BATHS AND WASHHOUSES, PUBLIC.

BATHS AND WASHHOUSES, PUBLIC. Until within a very few years there were in England no public bathing establishments which in any measure answered to the *Thermæ* of the Romans [BATH], places where, for a very moderate sum, the poorer, as well as the more affluent classes, might enjoy the use or the luxury of a warm, a tepid, or a cold bath. There were numerous "Baths," but they were private ones of a comparatively expensive character. It is certainly remarkable that the metropolis of England should have been so long behind that of other countries in providing inexpensive and convenient public baths. But so it appears always, or almost always, to have been. Among the vestiges of Roman London the remains of baths, and especially of warm baths, have been frequently discovered in the course of excavations made both within the walls of the ancient city and outside of them. Even at the present day, in one of the curious narrow lanes which extend from the Strand downwards to the Thames, called Strand Lane, may be seen one of these old Roman baths, with the clear spring flowing into it, and still quite available for its original purpose. Remains of another Roman bath, which were found in digging for the foundations of the Coal Exchange, have also been preserved, and may still be seen. Like the other Roman baths found in London, these, however, belonged evidently to private houses; but it is probable that public baths were provided for the use of the citizens. In Rome, as we have seen [BATH], the public baths were numerous and on a magnificent scale. In other cities there were also public baths; nor is it likely that *Londinium* was unprovided with them, though they were perhaps of a comparatively humble class. Be that as it may, there are no traces or records of public baths in the city subsequent to the Roman dominion. The citizens, however, had their Thames, not then a polluted stream; and there were several smaller streams, now diverted or wholly lost, or else perverted into sewers. There would seem, moreover, from the statement of Fitz Stephen, who wrote in the reign of Henry II., to have been wells or springs which were resorted to for bathing. It is not clear however, that these were properly bathing-places, though, from the way in which Stow speaks of them, it is likely they were. Stow (1598) especially mentions a bathing-place well known in our own time: "Somewhat north from Holywell is one other well, carved square with stone, and is called Dame Annis the Clear; and not far from it, but somewhat west, is also one other clear water, called Perilous Pond, because divers youths, by swimming therein, have been drowned." There is little doubt that swimming was always practised by the London youths wherever they could find a place fit to swim in, but baths, except for medicinal purposes, do not seem anywhere in England to have been constructed. Where, from its natural heat or supposed sanctity, the water was believed to possess peculiar curative properties, baths were indeed erected at an early period. The baths of Bath were perhaps never wholly neglected from the time of the Romans, who were well acquainted with their qualities. In the Tudor period medicinal baths were in great repute. At Holywell, in Flintshire, is a very beautiful edifice, erected by the mother of Henry VII., the lower part of which served the purpose of a plunging bath, while the upper part was a chapel; and the baths of Buxton were much resorted to before the Reformation. Still no public baths appear to have been anywhere erected for the mere purpose of ablution. In 1648, an ordinance granting to a Doctor Chamberlain, "that he might have the benefit of improving all baths for fourteen years together, for the good of the people," was read in the House of Commons, and committed; but his "improvement," no doubt referred to medicinal

BATHS AND WASHHOUSES, PUBLIC.

baths. It was not till the reign of Charles II. that the want of public baths was, in a measure, supplied; three or four *bagnios*, as they were called, being then erected in London. These were, however, only for the wealthier classes, the charge being 4s. for each person; and, in fact, they were in a measure medicinal, being for "sweating, hot bathing, and cupping;" and, as they are described as after the Turkish model, they were, no doubt, pretty much like the shampooing baths of the present day. These places became the resort of disreputable persons, and fell into discredit, the very name being long generic for a house of ill-fame. In the course of the 18th century, a few baths were opened. Perilous Pond, its name being changed into Peerless Pool, was in 1743, walled in, enclosed, and converted into an excellent swimming-bath. Others of a like character were formed in subsequent years; and during the present century there had come to be a good sprinkling of swimming-baths about the metropolis, as well as several establishments for warm and cold bathing. The warm baths were, however, almost invariably too expensive for general use, and the favourite resort for swimming was, as it still is, the Serpentine, in which as many as 12,000 persons, it is said, in a report of the Humane Society (1850), have been counted bathing at once, early on a Sunday morning. The canals in the vicinity of London were and are also resorted to by a large number of bathers.

But if baths of any kind were rare, public washing-houses or laundries were quite unknown. In olden days, indeed, the English were not wholly, or perhaps generally, home-washers. The housewife or the laundress carried the linen down to the nearest convenient spot by the side of a stream, where "the shore was shelvy and shallow," like that which the whitsters [washers] of Windsor resorted to, by Datchet Mead, where Falstaff was so unceremoniously slighted from the buck-basket. It is on record that the corporation of Reading, upon the suppression of monasteries, petitioned for the grant of the Friary in that town, for a town-hall, because their old hall stood by the river Kennet, near the spot which was used by the townswomen for washing clothes; and the corporation say in their petition that the noise of the women's clappers caused great interruption to the transaction of public business. These clappers were, of course, wooden ones. Washing in cold water, they used wooden battledores to beat their clothes, just as the *blanchisseuses* of the Seine do still. In the present day, washing by the river-side is, we believe, nowhere to be seen in England, but it is common enough in Scotland, Wales, and Ireland; and, as is well known, the Parisian laundresses pretty generally resort to washing-boats on the Seine. In Pepys's day, London families would seem to have sent their linen to be washed by their servants at some washing establishment; for that most valuable of diarists tells us, that on August 12th, 1667, he dined all alone, "my wife and maids being gone over the water to the whitster's with their clothes, this being the first time of her trying this way of washing her linen." Again he notes (August 19th, 1668), "This week my people wash over the water, and so I little company at home;" by which we may suppose that Mrs. Pepys was satisfied with her trial of "this way of washing her linen," as she continued to practise it for above a year.

It was reserved for our own day to establish public baths and laundries for the community generally, and for the poorer portion of it in particular. The practical philanthropist early saw that the sanitary improvement of the condition of the poor in our larger towns was a work loudly calling for accomplishment. Medical men, clergymen, city missionaries, parochial officers, and all whom either professional duty or benevolence had led to enter the dwellings of the very poor,

however their opinions differed in other respects, were at least unanimous in declaring that those dwellings exhibited a degree of dirt and squalor with which health and morality were alike incompatible. Many remedies for the evil were suggested, and several carried into execution. One little knot of practical men resolved fortunately to give their special attention to the matter of personal cleanliness. It had been allowed by all who were really acquainted with the homes of the very poor, that in their crowded and wretched dwellings cleanliness was impossible. In such places not only were there scarcely the means for personal cleanliness, but to wash and dry clothes properly was quite impracticable. It was proposed, therefore, to see whether the establishment of places where, for a small charge, a warm bath could at any time be had, and where all the conveniences for washing and drying clothes should be provided free of charge, or at a trifling cost per hour, would not be gladly accepted by the classes most requiring such conveniences.

The movement was practically initiated by the holding of an influential meeting at the Mansion House, under the presidency of the Lord Mayor, in September, 1844, when resolutions were passed for the formation of an "Association for Promoting Cleanliness amongst the Poor;" and an active subscription was commenced. The first experiment was made in a wretched locality near the London Docks, where in an open court, called Glasshouse Yard, Rosemary Lane, an old but capacious building, which had for some time been occupied by "sleeping-berths for the houseless poor," was rented and converted into the first "Free Baths and Wash-houses," and opened in May, 1845. A portion of the building was adapted, as well as it could be at a small expense, to the purpose, and furnished with a due supply of tubs and boilers, and with a few baths in various out-of-the-way recesses; and soap and soda, as well as hot and cold water, were provided gratuitously. The number of persons who availed themselves of the establishment was, in the first year, 27,662 bathers, and 36,577 washers; in the second year there were 84,584 bathers and washers. This, though the first establishment of the kind in London, was not the first in England; a very small one having been previously started, and with much success, in Liverpool, though without the knowledge of the London Committee. The Glasshouse Yard establishment owed its success solely to its usefulness. There was nothing extrinsic to render it attractive. It was placed in one of the worst spots in the metropolis; the building itself was as little suited to the purpose as any building well could be; the accommodation was of the most ordinary kind. Yet it at once proved—if proof were needed—that the poorest in that wretched neighbourhood would gladly be clean when the means were attainable. In August, 1846, a second, and much superior establishment, was opened in George Street, Euston Square; a plot of ground having been liberally offered by the New River Company, near one of their reservoirs, with the additional advantage of a free supply of water for the first six months. In the first year there were here some 113,000 bathers and 20,000 washers. This establishment, in which the baths are more varied in price than elsewhere, still flourishes.

The establishment third in point of date was, however, the first in importance and in the value of the consequences which resulted from it. In this the committee first fairly developed their plans. Although the building in Glasshouse Yard was opened gratuitously, it had been desired that the institution should as soon as practicable be rendered self-supporting by means of a small charge to each person who used it. The committee hoped too, to see the system extended throughout the country; and they rightly thought that nothing would so effectually and speedily further that object as to be able to show a Model Establishment, which, while it contained all the conveniences and appliances which those who availed themselves of it could desire, should be in itself all that science, combined with practical skill, could effect in the economy, suitableness, and completeness of its arrangements. Accordingly, architects and others were invited to send in designs for baths and laundries, and all the information which could be obtained was collected. The Model Establishment was then erected on a site which had been purchased in Goulston Square, Whitechapel, a very poor and crowded neighbourhood, but of ready access. The arrangements being almost entirely novel caused a very large original outlay, and many changes have been subsequently made; but as a whole they had been so carefully considered, and were so judiciously designed by Mr. Prichard Baly, the committee's engineer, that no material alteration has since been found necessary; indeed, in a recent Report of the Committee, we are told that "the general arrangements and mode of construction have been almost universally followed in London and the country."

In general character, then, these establishments are pretty much alike. A brief sketch of the interior of any one will serve to give a general conception of all, it being understood that there are differences of detail in each.

The baths for males and females are on opposite sides of the building, and separated in Goulston Square by the washing-room, in some others by the plunging-baths. In both sides are first- and second-class baths. The apartment in which these are placed is spacious and lofty, covered by an open roof, and lighted in the day by ample skylights; by gaslights at night. Each bath-room is a distinct compartment, somewhat more than six feet square, shut in by walls of painted slate, which are carried up to the height of some ten feet; but the top is

open, so as, while ensuring privacy, to admit of thorough ventilation. The bath, in some establishments sunk in the ground, in others placed as usual above it, is either of iron enamelled, or of zinc. The first- and second-class rooms are usually alike in every respect, except that the fittings in the first-class rooms are of a superior kind, and more complete than in the second. On each door is a porcelain knob, having a number painted upon it; a similar number is painted inside. An index outside enables an attendant to let in either hot or cold water, as the bather may direct. The charge for a first-class warm bath is usually sixpence, for which two towels, flesh and hair brushes, and a comb, are allowed. For a second-class bath the charge is twopence, but only one towel is allowed, and the bather must provide his own comb and brushes. The baths are in all respects alike, the same quantity of water (in most places forty-five gallons, but at St. Martin's much more) is allowed, and the bath is invariably cleaned after each person. The most perfect cleanliness is indeed observed in every respect. For a cold bath the charges are respectively threepence for a first- and one penny for a second-class bath: the regulations are the same as with the warm baths. The baths on the female side are similar to the others, but there is a little more taste in the first-class fittings. At Goulston Square there are only warm and cold baths. At St. Martin's a shower-bath is added. At George Street there are also vapour-baths. At all the more recently constructed establishments there are plunge or swimming baths filled with tepid water. For these swimming-baths the charge is usually fourpence for the first-, and twopence each person for the second-class. At the larger of the recent establishments there are two swimming-baths—a first and a second class; the smaller places have only one large bath, using it three days a week as a first-, and the other three days as a second-class bath.

The baths have everywhere proved exceedingly popular. The second-class baths are, in the summer particularly, always well attended, and of an evening there are generally many waiting for their turns, which are always strictly in the order of arrival.

The number of baths varies, of course, according to the requirements of the locality, and the size of the building. The number of first-class baths, for example, at St. Martin's-in-the-Fields, is twenty-four men's, five women's; of second-class, thirty-three men's, and eight women's. At Goulston Square, there are ninety-four first- and second-class baths. At St. James's, Marshall Street, there are only about fifty of both classes; but there is a swimming-bath. The number of bathers at Goulston Square in the year is above 150,000; at St. Martin's-in-the-Fields the number is above 200,000.

The *Wash-houses* are more remarkable than the bathing-rooms, because entirely unlike what is seen anywhere else. Along the centre, on one side, and at the ends of a large and lofty room, are ranges of little doorless and roofless compartments, the walls being of unpainted slate, and some six or eight feet high: these are the washing-places. At convenient points are the wringing-machines. Along one side of the room (at Goulston Square) is what looks like a range of wide but shallow deal drawers, turned up endways, the handles being one above the other—that is the drying apparatus. A long flannel-covered board is furnished for ironing on. In some of the latest wash-houses a mangle is provided.

Each washing compartment is 6 feet long by 3½ feet wide. At the end are two wooden troughs, which serve as a washing-tub and a boiler; these are furnished with taps for hot and cold water, for steam, and for letting off the waste water, so that the tubs are filled and emptied without any more trouble on the part of the washer than turning the tap, and without moving from her standing-place. The water in the boiler is made to boil by the admission of steam into it, which, as we said, the washer can do whenever she pleases. The ventilation is so arranged that the steam from each compartment is at once drawn upwards, and carried off to the great ventilating shaft.

The wringing-machine is in effect a sort of wide but shallow colander; the sides, instead of the bottom, being perforated, or rather formed of galvanised wire, so arranged that the meshes are about a quarter of an inch apart. When the wet clothes are put in this, it is set in rapid motion by a handle, which works a few connecting wheels; the clothes at once, by centrifugal force, arrange themselves around the sides, and the water is rapidly driven out between the wires, and carried off by water-pipes: an opening at the foot of the machine shows when the water ceases to flow, and when, consequently, the "wringing" is completed, and then the pressure of a lever at once stops the machine. The machine has rather a heavy look, but the turning of it is really very light work, and by it three minutes suffice to rid even a thick blanket of its moisture. The drying-chamber is a long chamber, heated by hot air to a temperature above 212°, and divided into numerous smaller chambers, so as to separate the clothes of the washers. Each division of the chamber contains a clothes-horse or maiden, one being allowed to each washer. In ten minutes or a quarter of an hour the clothes, unless very heavy or numerous, are quite dry. The committee have published a table in one of their reports, to show the rapidity with which the drying is accomplished. Some of the results are curious. We may take a single instance as an illustration of the processes we have been following. Three large dirty blankets weighed before being washed 9 lbs. 1 oz.; after washing they weighed 24 lbs. 14 ozs.; after leaving the wringing-machine, 12 lbs. 3 ozs.; after being dried, 8 lbs. 12 ozs. These blankets took 25 minutes to

dry, at a temperature of 210°. In all other cases the results were similar, establishing the fact that "the articles, when taken from the drying-chamber, contained decidedly less moisture than they did when they were received for the wash." To show the "satisfactory working of the drying-chamber at the model establishment, and also its great advantage in the economy of time, trouble, and expense to those of the labouring classes who resort to it," the committee give a return of the articles dried there in one week ending January 24, 1852. It is too full for us to copy; but we may state, that the number of articles of all kinds, from counterpanes, jackets, and trousers, down to shirts and stockings, was 36,844, belonging to 1373 washers, who occupied 2999½ hours in washing, drying, and ironing them; and that the drying consumed only 282 bushels of coke, which cost under 4*l*. In some of the buildings last erected, efforts have been made to economise still more the cost of this and other operations.

In most of the establishments there is only one class of washers; but in some there are both first and second classes, the difference being that the first class have a somewhat larger compartment allotted to each washer, and a third or rinsing-tub. The charge for the use of all the apparatus we have described is now generally 1½*d*. an hour, though in a few places it is only 1*d*. an hour. Where there are both classes, the charge is 2½*d*. an hour first-class, and 1½*d*. second. Soap, soda, &c., have to be found by the washers. The number of washing compartments varies, of course, according to the size of the establishment: at Goulston Square there are 84 of them; at St. Martin's, 56. The average time occupied by each washer at the model establishment is two hours and a half, and this is the general average time in London; in some country towns it differs considerably. In London it seems pretty well established, that the active wife of a labouring man can at one of these places wash and dry the clothes of her family in two or three hours. The ironing, at least in part, is generally done at home.

Let us look a little at what has been accomplished. In August 1846 the royal assent was given to an Act to encourage the establishment of public baths and washhouses, which, as amended in the session of 1847, empowered parish vestries and borough councils to establish such institutions, and, with the sanction of the Treasury, to borrow money for the purpose on the security of the borough fund or poor's rates. A schedule directs, among other very excellent rules, that baths must be provided in them at 1*d*. for cold and 2*d*. for warm baths; and that the washhouses shall be furnished with necessary conveniences at a charge not exceeding 3*d*. for two hours. Baths and wash-houses of a higher class are to be charged as the council and commissioners respectively think fit. The baths and washhouses "for the labouring classes" in any such establishment, must be not less than twice the number of those of any higher class. This Act at once gave the system a firm standing; and both boroughs and parishes have availed themselves of its powers to a considerable extent. Of course, it is not always easy to persuade vestrymen to permit an addition to be made to their parochial rates for a purpose that does not promise advantage to themselves; but as it has become year by year more evident that these institutions may be made self-supporting, and in due time repay the amount expended on their foundation, so there has been a growing readiness to found them. In London and the suburbs, besides the model establishment in Goulston Square, and that in George Street, Hampstead Road, there are several large parochial establishments, some of which are fitted up in an extremely complete manner, while all are well attended by both washers and bathers. Manchester and Liverpool have each several baths and washhouses, and almost every other large town throughout the country is either provided, or taking measures to be provided, with similar establishments; and the example has been followed by several of the smaller towns. Nor have the good effects of the movement been confined to this country. The Committee for Promoting the Establishment of Baths and Washhouses for the Labouring Classes were able, at the end of 1852, to state in the report before quoted, that the governments of France, Norway, and Belgium, the municipality of Venice, and the authorities at Hamburg, Turin, Munich, Amsterdam, Lisbon, and New York, had applied for and been furnished with information on the subject; and in some of these countries the example of England has since been followed in providing similar establishments for the labouring classes.

It is evident that the institution has become firmly established. In London alone the bathers number upwards of two millions a year, while the washers exceed half a million. The constantly increasing number of bathers and washers shows that the system is commending itself to a large section of the population. The experience of twelve years has proved that, with proper attention and economy, the establishments may be rendered self-supporting; and the observations of all who have watched them in particular localities vouch for their beneficial influences. The point in which they appear to have failed is, in reaching the very poorest. That portion of the community for whom the institution was primarily intended, seems to have been scarcely touched by it. Everywhere those who avail themselves of the benefits offered are of a class above the poorest. The most profitable section of the establishment is found to be the "first class." Whether availing themselves of the hint, the managers of these establishments might not, by furnishing a yet higher class bath (though still at a moderate price), provide the means by which they might support one of a cheaper kind than they have at present been

able to afford, and so extend the benefits of the system both upwards and downwards, is a question perhaps deserving of more attention than it has hitherto received.

BÂTMAN (pronounced Bawman), a soldier told off for a particular duty: as, when a battalion takes the field, and the tents are conveyed on horses, one bâtmán is allowed, by the "Queen's Regulations for the Army," to each of the field-officers, one to the staff, and two to each of the companies, for the care of the horses carrying the camp equipage; and those men are, for the time they are thus employed, exempted from all other regimental duties. The horses above specified are termed bâthorses, for the purchase of which the officer commanding the company is allowed a sum of money, and for which forage is provided by the commissariat. For regiments on duty in the kingdom, the bâtmán and bâthorse of course become unnecessary.

BATRACHOMYOMA'CHIA (*Βατραχομυομαχία*), the battle of the frogs and mice, is the title of a Greek poem, consisting of 294 hexameter verses. This poem, though generally ascribed to Homer, and printed with the editions of the Iliad and Odyssey, undoubtedly belongs to a late age, and is attributed by Plutarch and Suidas to Pigres, of Halicarnassus, in Asia Minor. Pigres is called by Suidas the brother of that Artemisia who was the wife of Mausolus. This poem, however, is probably the composition of some still later writer of the Alexandrine school. Some critics consider it a satirical poem: as it is not very long, the reader may form his own opinion without much trouble. Parnell has translated it into English verse.

BATTA, an allowance made to military officers in the service of the East India Company, in addition to their pay. As the officers of Queen's regiments serving in India receive their pay according to the scale fixed by her Majesty's regulations, and which pay is below the emoluments derived by officers of similar rank in the regiments of the East India Company, the allowance of batta is made also to them by the Company, and is so adjusted as to preserve an equality of income between the two services.

The scale of allowance under the name of batta varies not only with the circumstance of the regiments being in the field or in cantonments, but also according to the part of the country in which they are stationed.

Batta was originally given with the intention of enabling officers to provide for field-equipment, and for those extra expenses which they must incur when marching; but it early lost this character when it was continued to officers in cantonments. In November, 1828, the distinction was made between the amount allowed when in actual service, and when in cantonments; before that time no difference was made. The effect of the alteration is this: that at stations, whether in garrison or cantonment, within 200 miles of the seat of government of each presidency, where an officer formerly got full batta, he now gets half that batta, with an allowance for house-rent, which is inferior to what the other half of the batta would be. The half-batta of a lieutenant-colonel is 304 rupees (about 30*l*.) per month; his allowance for house-rent is 100 rupees. A major's half-batta is 228, and for house-rent 80 rupees per month; captain's half-batta, 91, and house-rent, 50 rupees; lieutenant's, 61, and 30 rupees; ensign's, 46, and 25 rupees. Colonels of regiments, not being general officers on the staff, nor holding offices specially provided for, are allowed the full batta of 750 rupees per month at any station, but they have not any allowance for house-rent. It was estimated that, by carrying into effect the regulation of November 1828, the government of the East India Company would save 12,000*l*. per annum. In the field, and in garrison or cantonment, beyond 200 miles of direct distance from the seat of government of each presidency, full batta is allowed: or rather the other half batta, which is now called extra batta.

BATTALION. This name is applied to a certain division of the infantry in an army, corresponding, nearly, to the *chiliarchia* in a Greek phalanx, and to the *cohort* in a Roman legion. The number of men composing a battalion is variable, but in the British service, according to the present establishment, it consists of ten service and two depôt companies, which at their service strength of 100 rank and file each, would give 1200 men; or 1000 with the service companies and 200 at the depôt. This is the strength in rank and file of a battalion on the Indian establishment, making, with 91 non-commissioned officers, trumpeters, and drummers, and 48 officers, a total of 1,339 of all ranks. The battalions on the home establishment consist likewise of 10 service and 2 depôt companies, or 950 rank and file—of which 150 form the depôt companies—25 drummers, 56 sergeants, and 46 or 45 officers, according as it is the first or second battalion, making a total of 1,077 of all ranks. A battalion of the Guards is somewhat smaller, there being only 10 companies, or 800 rank and file, which with 61 non-commissioned officers and drummers, and 38 officers, gives a total of 899 of all ranks. The number of battalions in a regiment varies; at present, of the three regiments of Guards, the Grenadier Guards is composed of three battalions, while the Coldstream and Scots Fusilier Guards contain only two each. Of the 100 regiments of infantry, the 24 first contain two battalions each; the 60th or Royal Rifle Corps, four battalions, and the rest one each. The Rifle Brigade consists of four battalions. There are, therefore, now, 138 battalions of British infantry, exclusive of the Royal Marines, three West India regiments and Colonial corps. And there are fourteen battalions of artillery, besides the Horse Brigade.

It seems, therefore, that, originally, the name of regiment was applied to the body of men organised for a particular district, or a particular branch of service; and that, when the numerical strength of the regiment exceeded what was considered convenient, it was divided into two or more battalions. Battalions may, therefore, be defined as the units of the modern tactical system and composition of infantry, which is arbitrarily divided into regiments. The number of battalions in a regiment varies much in the different armies of Europe; the strength of a battalion, however, is generally about 800 or 1000 men.

The phalanx of the Greeks, and the legion of the Romans, with their respective constitutions and divisions, will be described under the words PHALANX and LEGION.

The destructive effects of fire-arms among dense bodies of men necessarily caused the close order of battle used in ancient warfare to be abandoned: though, down to the middle of the 18th century, an opinion that the troops could not otherwise resist effectually a charge of the enemy, and the desire to form them with facility into a column for attack, induced commanders of armies to draw up the battalions in a line from four to six files deep. But the numerous casualties which still occurred, led subsequently to the practice of forming the line in three ranks; and in the present regulations for the disposition of the British army, it is prescribed that the battalions are to be drawn up in two ranks only. The argument in favour of this method, which, it may be observed, was recommended, in 1783, by Turpin, the commentator of Vegetius, is, that in action two ranks of men only can fire at once, and as the third rank can only be employed in loading, and handing the muskets to the men in their front, this service scarcely compensates for the loss occasioned by the exposure of so many men to the enemy's fire. This is fully borne out by Marshal Marmont, Duke of Ragusa, in the following passages, which are extracted from a translation of his work which appeared in the 'United Service Journal,' for February, 1845: "Nothing can be said in favour of a third rank, for without entering into a detail of volleys, persons of experience know that if one can, at a review, fire a volley in three ranks, it is impossible in war." A foreign writer, however, contends that with soldiers as well disciplined as those of Russia, three ranks would be more advantageous than two: since the men in the middle rank are enabled to fire a second time with the muskets obtained from those in the third rank, immediately after they and the front-rank men have made their first fire, so that a much less interval takes place between the volleys than that which occurs when the line consists of only two ranks. Marshal Marmont says it is ascertained to be impracticable to hand over the firelock to the third rank as the French order prescribes. "This method, being merely theoretical, is by no means applicable to the face of an enemy. In fact, the third rank, of its own accord, in a few moments, forms into the other two; the most advantageous formation is, therefore, instinctively adopted; but as the change is made contrary to order, there results from it a kind of disorganisation."

During the wars which arose out of the revolution in France, the armies of that nation became habituated to a formation in close columns instead of a line of small depth. This practice, which seemed to be a return to the tactics of the ancients, possesses some advantages when an attack is to be directed against an enemy's line which is too far extended to allow the divisions to succour each other in time; and the great merit of Napoleon consisted in manœuvring so as to lead his opponent to fall into this error, and then overwhelming him by numerous consecutive and powerful attacks directed against the weaker part of his line. The system, however, seems to have been persevered in too tenaciously by the French generals; for against steady troops, their columns not only suffered serious losses in making the assaults, but were incapable of keeping up a fire equal to that which might have been produced by a more extended order. Such was the error committed by Marshal Soult at the battle of Albuera. According to Napier ('History of the Peninsular War'), "that general persisted beyond reason in fighting with dense columns, and thus lost the fairest field ever offered to the arms of France. Had the fifth corps of the French opened in time," the historian observes, "nothing could have saved the British army from a total defeat."

A battalion of 800 men, that is disregarding the dépôt, is divided into ten companies; and, for convenience in performing the movements which may be required, each company is subdivided into two equal parts, and each of these into sections. The battalion is commanded by its own colonel; and several battalions or regiments are, on service, united under one general officer; these constitute a brigade, and may be considered as a small legion. According to the present regulations each man occupies in line 21 inches, and, as no intervals exist between the companies, the extent of a battalion formed two deep, is about 240 yards. Six paces are left between every two battalions, and the same interval only separates one brigade from another.

The company of grenadiers occupies the extreme right, and the light company the extreme left of the battalion: these are called the flank companies, and the others take their places from right to left, according to the numbers by which they are designated. The captain, or officer commanding each company, is stationed in the front rank on the right of his company; and immediately behind him, in the rear

rank, is his covering sergeant. The lieutenants, ensigns, and the sergeants of the companies form a third, or what is called a supernumerary, rank in rear of the others, at the distance of three paces. The two regimental colours are placed in the front rank between the two centre companies, and two non-commissioned officers are in the rear rank behind them; a sergeant is stationed in the front, between the colours, another stands opposite to him in the rear rank, and a third in a line with both, in the supernumerary rank. These last-mentioned sergeants serve to direct the march of the battalion when it moves parallel to its front; for which purpose, on that occasion, they form themselves in a line in that direction, and march before the battalion at the distance of six paces.

The commander of the battalion places himself in front when he has to superintend the ordinary exercises, otherwise his station is in the rear. The lieutenant-colonel is behind the colours in rear of the supernumerary rank; the majors are in rear of the second battalion companies on the right and left flanks respectively, and the adjutant in a line with them, opposite to the centre. The situations of the *Staff* of the battalion, the musicians, &c., together with the particulars above briefly stated, are fully described in the treatises on the field exercises and evolutions of the British army.

Originally the grenadiers performed the duty of throwing hand-grenades, or small iron shells charged with powder, among the enemy; and the firelocks of the fusiliers and light infantry were different from those of the other troops; but, at the present day, all the infantry of the line carry the same kind of musket, namely, the Enfield rifle.

The principal evolutions of a battalion consist in reversing the front of the line, taking a position at right-angles to its actual front; forming a column by bringing the different companies or their subdivisions parallel to, and directly in rear of each other, either at open or close intervals; forming a column *en échelon*, or with the divisions parallel to, but in positions receding from, each other towards the right or left, in the manner of steps; or, lastly, forming a hollow square. By changing the front, a retrograde movement in line may be made; by forming the line perpendicularly on either flank, an attempt of the enemy to turn it may be opposed. Columns are formed for the purpose of marching along roads or through defiles, or advancing in a body towards an enemy's position; a movement *en échelon* allows troops to gain ground obliquely towards the front or rear; and a hollow square is formed in order to resist an enemy in every direction, when the battalion is in danger of being surrounded.

(Turpin de Crissé, *Commentaires sur les Institutions Militaires de Végèce*; Daniel, *Histoire de la Milice Française*; Okounef, *Examen Raisonné des Propriétés des Trois Armes*; Bismark on the *Tactics of Cavalry*, translated by Major Beamish; *Regulations for the Formations, Field Exercises, and Movements of her Majesty's Forces*. For many particulars relative to the present state of the British army, the *Monthly Lists* may be consulted. See also *R. E. Aide-Mémoire*, art., Evolutions of Infantry.)

BATTARDEAU. [COFFER-DAM.]

BATTENS. One description of sawn fir timber planks of small dimensions, imported from the north of Europe, or from America, is known in commerce under the name of *battens*, by way of contradistinction to the other descriptions known respectively as *deals* and *planks*. Battens are of various lengths, from 10 to 14 or occasionally 16 feet, and generally 7 or 6½ inches wide by 3, 2½, or 2¼ inches thick; they are sold, however, by what is called the Petersburg standard, which is equivalent to 120 battens 12 feet long, 7 inches wide, by 2¼ inches thick. The present duty upon their importation is at the rate of 10s. per load of 50 cubic feet, from foreign countries; or 2s. per load when of or from British possessions; in the latter case 5 per cent. additional duty is charged. The best battens come from Norway or St. Petersburg.

Battens are principally used for flooring purposes, or for covering roofs to receive slating, on account of their being less exposed to shrinking than other plank stuff, owing to their smaller scantling. It is customary to cut the 2½-inch battens, as imported, into two boards for floors, and into three boards for slating; sometimes in inferior floors battens cut into three boards are also used.

In joiner's work the term *batten*, or *battening*, is used to express the species of framing immediately attached to a wall, which subsequently receives any paneled wainscoting, or a canvas lining, introduced for the purpose of isolating the paper from the wall itself, or even of isolating the plastering of a room from the wall, if there should be any danger of the latter affecting the decorated surfaces by its humidity, or by its tendency to "saltpetre." In such cases the battens are usually made about 2¼ inches wide by 1½ inches thick, and are placed at clear distances asunder of from 7 to 12 inches, according to the nature of the surface they are designed to receive; when the battens are intended to receive canvas they are made wider, but are placed at rather greater intervals. Sometimes the laths nailed at intervals upon the common rafters of a roof to receive the nails of the slating, or the hook of tiles, are called incorrectly *battens*.

BATTERING RAM. [ARTILLERY.]

BATTERY (IN LAW). [ASSAULT.]

BATTERY, (ELECTRICAL and GALVANIC, or VOLTAIC). [ELECTRICITY.]

BATTERY. This name is given to any number of pieces of ordnance

placed behind a parapet, or elevation of earth, either to defend a position, destroy the works, or dismount the artillery of an enemy. It likewise means the equipment of a certain number of pieces of artillery. [FIELD ARTILLERY.]

It may be said that the ancients made use of a species of ordnance in the operations of attack and defence; and the battering-rams, the balistæ, and the catapultæ, which, when placed on the natural ground, or in buildings of timber, or elevated on mounds of earth, served the besiegers to demolish the walls of fortresses, or to drive the defenders from them, may be considered as corresponding to the guns, mortars, &c., which constitute the armament of a modern battery.

Vitruvius states ('De Architecturâ,' lib. x.) that Cetrus of Chalcedon was the first who covered the ram with a shed, in order to secure the men who worked it from the arrows, darts, and stones thrown by the enemy; and he adds, that the construction of the shed was subsequently improved by the engineers of Philip and Alexander. The *testudines* and *helépoles* were buildings of this nature, for the protection of the men and military engines, and in this respect they correspond to the parapets and *épaulements*, which cover the ordnance at present employed in the attack of a fortress. (See the description of the *helépolis* (ἐλέπολις) of Demetrius. Plutarch, 'Life of Demetrius,' cap. 21.)

While the same species of artillery continued to be used in warfare, it is evident that no material change could take place in the nature of the edifices constructed to cover it; but from the epoch of the invention of gunpowder, the wooden sheds or towers were superseded by masses of earth, whose thickness was necessarily made greater than the depth to which a cannon-shot can penetrate into them. In modern times the designation of a battery varies with the purposes to be accomplished, the nature of the ordnance employed, and the manner in which the firing may be made.

A *breaching battery* is one which may be placed at between 50 and 1000 yards from any wall or rampart, in order to demolish it; and the effect is produced at all times by firing perpendicularly to the front to be breached, and, if near enough, *point blank* at it; such a battery generally, therefore, has its front parallel to the face of the wall to be breached.

An *enfilading battery* is one whose parapet is perpendicular to the produced line of the enemy's rampart; so that the shot from the guns may graze the interior side of that rampart or its parapet, in the direction of its length. When shot discharged from pieces of ordnance make successive rebounds along the ground, the firing is said to be *à ricochet*, and the battery a *ricochetting battery*; and this mode of firing is employed when it is intended to dismount artillery by enfilading a rampart. The effect is produced by giving to the axis of the gun an elevation of between six and nine degrees above a line passing from its chamber through the crest of the enemy's parapet in front; and, according to the latest experiments, the distance at which a battery should be placed from the nearest extremity of the rampart to be enfiladed by ricochet firing is between 400 and 600 yards: at a greater distance than the latter much of the ammunition would be expended without effect.

A *gun battery* is one in which guns only are employed, for either of the purposes above mentioned, or to defend any ground, by a fire of round or solid shot.

A *howitzer battery* is one in which howitzers are employed. This species of ordnance throws shells, or hollow shot, generally at a small elevation of the axis to the horizon; and it serves to produce, by the bursting of the shells, a breach in a rampart of earth; or, when fired *à ricochet*, to destroy the palisades or other obstacles which might impede the troops in assaulting an enemy's work. Howitzers are also used in conjunction with guns, to form breaches in ramparts of brick or stone.

A *mortar battery* is one in which shells are thrown from mortars at a great elevation of the axis of the piece; so that, by the momentum acquired in falling, they may crush the roofs, and by their explosion complete the destruction of magazines or other buildings. This is called a *vertical fire*. By employing large charges of powder, a very extensive range has been produced by mortars; for, at the siege of Cadiz, the French are said to have sent shells to the distance of more than three miles from the battery.

When the battery is mounted on a natural or artificial eminence, in order to allow the guns to fire from above downward, or to make what is called a *plunging fire* against or into the works of the enemy, it constitutes a *cavalier battery*; and when the guns are elevated on a platform, or on tall carriages, so as to be enabled to fire over the superior slope of the parapet or *épaulement*, the battery is said to be *en barbette*. This kind of battery is usually executed at the most advanced points of a fortress, for the purpose of allowing considerable lateral splay in the direction of the artillery to the right or left; by which means the reconnoitring parties of the besiegers may be annoyed while at a distance and in motion.

In the formation of any of the field batteries above mentioned, while they are beyond the range of the enemy's musketry, they may be executed without cover for the working parties, like any simple breast-work, after the outline has been traced on the ground by the engineers; but when the men employed in the work would be much exposed to annoyance from the enemy's fire, it becomes necessary that they should be protected by a mask of *gabions*. [GABION.]

These being planted on their bases along the exterior side of the intended trench in front of the battery, permit a cover, which a musket-ball cannot pierce, being soon obtained. Within this line of gabions the excavation is commenced, and part of the earth obtained from the trench is thrown into and beyond the gabions, till the covering mass is thick enough, if necessary, to be proof against a cannon-ball: the men thus work in comparative security to raise the parapet with earth, which they do generally to the height of about seven feet from the ground, and to the thickness of eighteen or twenty feet, not including the breadths of the slopes given to the exterior and interior sides. The exterior slope is generally left with that inclination which earth, when thrown up, naturally assumes, that is at about 45° to the horizon; but the interior slope being necessarily more steep, in order to allow the guns to be brought close up to it, is retained by a *revêtement* or covering, either of *fascines* [FASCINES], gabions, or sand-bags, bags full of earth. Batteries are termed *elevated*, *half-sunken*, or *sunken*, according to their method of construction. The parapet of the elevated battery is constructed of earth obtained from the ditch; of a half-sunken battery, part from the ditch and part from the interior; and of a sunken battery, wholly from the interior.

The *embrasures*, or openings in the parapet, through which the guns are to fire, are, at the *neck* or interior extremity, about two feet wide, and at the exterior about half the thickness of the parapet: each of their sides or cheeks has a small declination from a vertical plane, so that the breadth of the opening at top is rather greater than at the bottom, or on what is called the *sole* of the embrasure, in order that the flame from the muzzle of the gun may be less liable to damage those sides: for the same reason the latter are lined with fascines, or which is preferred, with gabions, at the neck of the embrasure. The interval between two embrasures is called a *merlon*; and the part between the *sole* and the ground within the battery is called the *genouillère*.

The guns rest on platforms, generally of timber, either of a rectangular or dovetailed figure. [PLATFORM.]

Besides the parapet which forms the front of the battery, a wing is constructed of the same materials on each side, called an *épaulement*, in order to protect the interior from any enfilading fire of the enemy. MAGAZINES are always formed either within or near the rear of the battery, to contain the ammunition for its service, in the proportion of one magazine to three or four guns: this is generally a rectangular pit, sunk to about three feet below, with sides and a roof of timber rising about as much above, the natural ground: the roof is covered with earth of a thickness which may be capable of resisting the momentum of a shell, and the descent to the floor of the magazine is by an inclined plane towards the rear. *Traverses*, or elevations of earth, revetted at the sides generally by gabions, are formed at intervals in the interior of the battery, to afford protection for the men against such shot or shells of the enemy as may fall there.

Howitzer and mortar batteries are executed nearly in the same manner as the others, except that mortar batteries never have embrasures, and the embrasures of a howitzer battery are made of a peculiar shape. [EMBRASURE.]

Some further particulars of batteries will be found under SIEGE.

BATTLE-AXE, a military weapon of offence used in different countries from the remotest times. Sir Samuel Meyrick says, as it was suggested by, so it immediately followed, the invention of the hatchet. The two Greek names for the battle-axe, ἀξίνη (*axine*), and πέλεκυς (*pelekus*), occur in Homer in the same verse, 'Il.' O. l. 711. What was the precise difference between the two weapons we are not told by ancient writers, but it seems probable that the *axine* was similar to our hatchet, while the *pelekus*, which is usually translated in Latin by *bipennis*, had evidently two heads or edges; for Homer mentions another instrument of the same kind in the 23rd book of the 'Iliad,' called ἡμιπέλεκον (*hemipelekon*), or the half-axe. Suidas interprets ἡμιπέλεκτα (*hemipeleka*), by αἱ μονόστομοι ἀξίνοι, one-edged axes. (See Kuster's note on ἡμιπέλεκτα.) The *pelekus*, or *bipennis*, was also called *securis Amazonica*, the Amazonian axe, from its being supposed to have been used by those female warriors. The best representation of the ancient form of this *bipennis* is probably to be found in Petit's 'Dissertatio de Amazonibus,' 8vo, Amst., 1687, where it appears on the reverse of a coin of Thyatira, as well as upon the reverses of two coins of Marcus Aurelius. Numerous other coins of great antiquity bearing the *bipennis* are referred to in Rasche's 'Lexicon Rei Nummarie,' tom. i. col. 502, et seq.; 'Supplem.' tom. i. p. 596.

Among the nations and tribes who joined the great expedition of Xerxes, we find battle-axes among the Sacæ (Herodot. vii. c. lxiv.), and the Egyptians (ibid. c. lxxxix.) Brennus, at the siege of the Roman capitol by the Gauls, was armed with a battle-axe. The Vindelici fought against Drusus with the battle-axe. (Horat. 'Carm.' iv. 4.) Tacitus, speaking of a later period ('Hist.' ii. 42), describes Otho's forces as cutting through helmets and breastplates with their swords and axes (*gladiis et securibus*). In the Roman armies, however, we do not find the battle-axe in ordinary use. It seems to have been considered as the weapon more peculiarly used by uncivilised nations. Ammianus Marcellinus (fol. Par. 1681, lib. xix. c. vi.), under the year 359, describes a body of Gauls as furnished with battle-axes and swords.

The introduction of the battle-axe into this country has been

frequently attributed to the Danes; but proofs of an earlier use of it in our islands are deducible. Mr. Hayman Rooke, in a memoir printed in the 'Archæologia' of the Society of Antiquaries, has engraved a fragment of a battle-axe found among some Druidical remains at Aspatria in Cumberland, in June 1789 ('Archæol.' vol. x. p. 113); and in the same volume (pl. xl.) are two representations of the old Galwegian bill or battle-axe, each two feet six inches long, found in a moss near Terreagles. Remains of others are stated to have been found among the barrows on the downs of Wiltshire, and in the north of Scotland. The Saxons used an axe with a long handle, which they called a bill; this continued long in use, and became the pole-axe and bill-hook of modern times: they had also the double-axe, or twy-bill. The Danes and Norwegians, however, probably made more use of this instrument than any other nations of their time. That the battle-axe was used in England in the Saxon times, we have the authority of different MSS. of the 9th century, and the English are represented as using it, in the Bayeux tapestry. Axe-heads of flint and of bronze have been found in many of the tumuli opened in various parts of this country; and others of a similar kind in those of Denmark (see the 'Archæologia,' and the Journals of the Archæological Association, and Institute, *passim*, Akerman's 'Archæological Index,' and Worsaae's 'Primeval Antiquities of Denmark,' translated by Thoms).

At the battle of Stamford Bridge, between Harold of England and Harold Harfager of Norway, when the Norwegians gave way and the English pursued them, a total stop is stated to have been put to the pursuit for some hours by the desperate boldness of a single Norwegian, who defended the pass of the bridge with his battle-axe. He killed more than forty of the English, and was himself at last slain only by stratagem. (Hen. Huntingt. l. vii. 211.) Ware, who wrote in the time of Henry II., mentions the gisarme (a word spelt in a variety of ways by different writers), which seems to have been a species of double-axe, with a cutting weapon projecting beyond the transverse points of the axe.

When King Stephen was taken prisoner by the Earl of Gloucester, we are told by Gervas of Canterbury that he had broken his battle-axe in pieces before he took to his sword, and was even then brought down by a stone. (Script. x. Twysd. col. 1354.)

During the middle period of English history we read but little of this weapon, though it appears to have been constantly used. The Welsh infantry at the battle of Agincourt, in 1415, found it particularly serviceable in despatching those whom the archers had wounded with their arrows. In Strutt's 'Manners and Customs of the English,' vol. ii. pl. xlv., Henry V. is represented as setting Richard, Earl of Warwick, to keep Port Quarternyle, at the siege of Rouen, by the delivery of a battle-axe.

Toward the close of the 16th century, the battle-axe, as a weapon of war, seems to have fallen into gradual disuse; although the occasional placing of a pistol in its handle, in some specimens which remain, seems to bespeak a wish on the part of the warriors of that period that it should be retained with an improved use.

Grose, in his 'Military Antiquities,' vol. ii. pl. xxviii. fig. 4, and pl. xxxiv. fig. 3, has engraved a Lochaber axe and an ancient battle-axe. Sir Samuel Meyrick, in his engraved illustrations of ancient armour now at Goodrich Court in Herefordshire, pl. lxxxiii., has engraved numerous specimens of battle-axes and pole-axes, from the time of Henry VI. to one of the year 1685, which is of Dutch origin, bearing the date, and the handle being ornamented with ivory.

The battle-axe was used at a very early period in naval fights, chiefly to cut the ropes and rigging of vessels. (See Scheffer, 'Mil. Nav.' ii. 7.)

BATTLE, WAGER OF. [APPEAL.]

BATTLEMENT, a parapet wall, usually indented, originally intended for the protection of soldiers in military works; but in Gothic architecture, and especially English Gothic, commonly employed in ecclesiastical as well as castellated edifices. [GOthic ARCHITECTURE.] The battlements are of very remote antiquity, as remains of them still exist in Greece and Italy (see Mazois' 'Ruines de Pompeii,' and Stuart's 'Athens'); and they are represented in Egyptian paintings and Assyrian sculpture. The modern battlement, however, is better known as belonging to buildings from the 11th to the end of the 16th century; but it was not in general use in ecclesiastical edifices until the middle of the 12th century.

The battlement is generally indented, with a coping sloping both ways from about the centre; the lower part, between the coping and the cornice of the building, is often pierced and decorated. Although by the word battlement is generally understood the whole indented parapet wall, the term may perhaps with more propriety be applied to express rather the higher part of the wall, in contradistinction to the indent, interval, or embrasure. It is possible that the term battlement may have derived its name from the facility afforded to soldiers of doing battle under the protection afforded by the higher part of the indented wall. Battlements offer in their proportions, and in the details of their mouldings and ornaments, a great variety of examples.

Few Norman battlements remain. Usually, during the Norman period, the battlement seems to have been a plain parapet without intervals; and, if decorated, the decoration probably consisted of the semicircular arch, the peculiar feature of the Norman style. The

upper part or rim of a Norman font, decorated with semicircular-headed panels, in South Hayling Church, Hampshire, appears to be an imitation of such a parapet. The Norman church of l'Abbaye aux Dames, at Caen in Normandy, has a parapet decorated with pointed-arched-headed panels, which at the introduction of the pointed-arch style most probably supplanted the old semicircular-arched panel, similar to that at Hayling Church.

During nearly the whole period of the First Pointed, or Early English style, the parapet was seldom indented; and in many buildings it was plain, in others decorated. At Salisbury, it is executed with a series of arches and panels, and in Lincoln Cathedral with quatrefoils in sunk panels. A battlement of equal intervals occurs in small orna-

Battlement.

Trefoiled arches and corbels under battlement.

[Salisbury Cathedral.]

mented works erected about the close of this period, when this First Pointed or Early English style gave way to the Second Pointed, or as it is ordinarily denominated, the Decorated English style.

During this Second Pointed period, the parapet wall without indentations continued frequently to be used; but it is often pierced through in various forms, generally consisting of quatrefoils, and quatrefoils in circles. Another form, however, which is not so common, may be considered more beautiful. This is a waved line, the spaces of which are trefoiled. In St. Mary Magdalen Church, at Oxford, there is a

[Mary Magdalen College, Oxford.]

good example of this kind of battlement. Of the plain battlements, that which was most in use in this period has the embrasures or intervals narrow, and is surmounted with a capping moulding placed in a horizontal position as at Waltham Cross; but there are some

[Waltham Cross, as restored from the ancient fragments, by W. B. Clarke.]

battlements of the same date with the capping running both vertically and horizontally, of which there is a fine specimen in the tower of Merton Chapel, Oxford. In some small works of this style a flower is occasionally used as a finish above the capping, moulding, or cornice, but it is by no means common. The nave of York Cathedral presents a fine example of the pierced battlement so prevalent during this period; it consists of arches or arched panels, trefoiled or cinquefoiled, and the interval is a quatrefoil in a circle; the whole is covered with a moulding running both horizontally and vertically.

In the battlements belonging to the Third Pointed or Perpendicular style, parapets without indentures still continued to be used occasionally; the serpentine line with the trefoil was also still in use, but the line dividing the trefoil was more frequently made straight, and the divisions were consequently formed into triangular panels. But in the early and best works, the trefoils are not divided by straight lines. One of the finest examples of panelled parapets is at the Beauchamp Chapel, at Warwick, consisting of quatrefoils in squares, with shields and flowers. There are many varieties of pierced battlements belonging to this period. Those erected in the early part of it have commonly quatrefoils, either in the lower compartments or above the panels of the lower compartments, forming part of the higher panels. Two heights of panels are also frequently employed in battlements of this period. At Loughborough there is an example of a fine battlement, consisting of rich pierced quatrefoils in two heights. Such battlements have generally a moulded cornice running round the battlement and the embrasure. A few edifices of a later period have pierced battlements ornamented with pointed compartments, as in the tower

of Lincoln Cathedral, the Tomb-house at Windsor, the Lady Chapel at Peterborough, and the great battlement at King's College Chapel, Cambridge. Sometimes on the exterior of a building, and often within, the Tudor or three-leaved flower, forming a point at the top, is used

[From the tower of Lincoln Cathedral, from a sketch by G. Moore, Arch.]

on the battlement, as at the screens in the choir of Exeter Cathedral; and there are a few instances of the upper part of a battlement analogous in form to it, in small works erected long before this date—as at Northampton Cross. But Waltham Cross, erected at the same

[Northampton Cross, from an original sketch by G. Moore, Arch.]

time, is without this finish. Some battlements of this period, especially in very rich designs, have, in lieu of the Tudor flower, a finial on the top of pierced quatrefoils, as at Woolpit and Blithborough Churches in Suffolk and Norfolk. Of plain battlements in the Perpendicular style there are many varieties. Some are formed with nearly equal intervals, and with a plain coping placed both horizontally and vertically. Castellated battlements have the embrasures between the battlements nearly equal to the width of the battlements themselves; sometimes

[Turret of King's College Chapel, Cambridge.]

they have wide battlements and narrow embrasures, with the coping moulding placed horizontally, and the sides cut plain. Another battlement consists of a moulding running round the battlement and the embrasure, while a capping is set upon the horizontal part of the embrasure and battlement, as at York Minster. The most common

[York Minster.]

battlement towards the close of this period has a broad cornice, consisting of several mouldings, running both vertically and horizontally, the embrasures being very often much narrowed and the battlement enlarged.

The battlement, which was originally designed for the protection of the besieged, became afterwards merely an ornament to an edifice;

being used as an ornament to the transoms of windows, and in other curiously inappropriate positions. A most remarkable example of the

[Buttress, with battlements, at Loddon Church, Norfolk.]

excessive use of it as a decoration is shown in the annexed cut, representing the top of a buttress at Loddon Church, Norfolk.

BAXTERIANS, a name which is applied to those who adopt the theological system of Richard Baxter. The name is now almost extinct; but Baxterianism is still the resting place of many who do not approve of the extremes of Calvinism. The Baxterians hardly ever attained the rank of a separate denomination, even when they were most numerous; and they are now completely scattered among different communions. Their writings are most popular among the orthodox dissenters.

Baxterianism occupies a sort of middle place between Arminianism and Calvinism. It is not correct to say that it reconciles the two schemes. It only connects them by showing that portions from each may be made to harmonise with each other. Hence it would be more properly described as a system of theology framed out of the systems of Calvin and Arminius, and becoming itself the point of union between them. Its chief merit is supposed to consist in the amalgamation of the Arminian doctrine of free grace with the Calvinistic doctrine of election. The Baxterians profess to believe that a certain number, determined upon in the divine counsels, are elected to salvation without respect to their good works. To this extent they receive the doctrine of effectual calling. But to make their view of the operation and comprehensiveness of divine favour complete, they contend that all to whom the gospel is preached are placed in a condition for securing their own salvation. Hence they think with Calvin that Christ died in a special manner for the elect; and, in a more general sense, for all others who come within the light of the gospel. The Calvinistic tenet of reprobation forms no part of their system.

The grounds on which Baxter contended that the death of Christ put all men in a state of salvation are briefly these: 1st, Because Christ assumed the human nature, and bore the sins of the human race; 2nd, Because pardon and life were offered to all mankind on condition of acceptance,—“Whosoever believeth shall be saved;” and, 3rd, Because it is not to the elect alone, but to all men, that the benefits of the gospel are proclaimed.

The arguments by which the learned divines of this school prove the elect to have a superior interest in the death of Christ over the non-elect, are deeply tinged with that metaphysical subtlety of which Bishop Burnet complains as the great blemish of Baxter's writings. The hypothesis, in a few words, may be thus stated: that Christ has made a conditional gift of the benefits accruing from his death to all mankind; but to the elect the gift is absolute and irreversible; from which he draws the inference that, notwithstanding the *positive* possession of these advantages was decreed to the few, yet conditionally the benefit was extended to all.

The Baxterians are greatly opposed to Antinomianism. Faith without works they hold to be an unscriptural and dangerous tenet. Several of the minor doctrines of Calvinism are adopted in a modified sense, among which may be mentioned justification and the perseverance of the saints. They advocate the certainty of perseverance, but incline to the opinion that it may be lost by too weak a degree of saving grace.

In all the Baxterian deviations from the system of Calvin there is a decided leaning to more comprehensive views. Baxter was himself opposed to the narrowing of the terms of salvation, and designed to remove every appearance of exclusiveness in the operation of divine favour from the system which he took such pains to adjust and promulgate. The most eminent divines who have embraced these opinions since the death of their author are Watts and Doddridge—men who have both illustrated in their works and lives the candid and amiable spirit of the school to which they belonged.

(Calamy's *Abridgment of Mr. Baxter's History of his Life and Times*, 2nd edit. 1713; Baxter's *Catholic Theology*; Buck's *Theological Dictionary*.)

BAY, in architecture, a division or compartment in a building formed by the main ribs of the vaulting, the principals of the roof; the main beams or arches, pillars, pilasters, or buttresses, or any other principal features which divide the building into corresponding compartments. The space between the mullions of a window is also sometimes, but improperly, called a bay: it is more correctly called a light.

BAY-SALT. [SALT.]

BAY WINDOW. [ORIEL.]

BAYADEER (said to be a corruption of *Bailadeira*, a Portuguese word, which signifies a dancing woman), a name given to the regularly-bred dancing girls in India, who are also the regular prostitutes. Among the Hindu Brahmins, female children are devoted, before their births, under a vow of the parents, to the service of the deity Mahadeo, and these are received into some of his temples. They are brought up in the usual accomplishments, and the wages of their exertions and their infamy enter the treasury of the temple with which they are connected. Mr. Maurice ('Indian Antiquities') says that the priests of these pagodas, as he calls them, induce young females to enter, that every pagoda has a band of them, who dance before the idol, to whom they are considered as wedded, and that they are not considered as at all disreputable. If there is any offspring from their promiscuous intercourse, boys and girls are both considered as consecrated to the idol: the boys are taught to be musicians for the festivals; the girls have to lead a similar life to their mothers. Bernier's account, of a much earlier date, is of a like character. The Mohammedans of India have also their dancing-girls, of the same character, but who are generally provided by women who make it their business to select handsome children, teach them the necessary accomplishments, and subject them to the same infamous life; but though called bayadeers, they are not devotees of the temples.

These girls are generally introduced to any party that requires their attendance, escorted by a band of musicians. A native band consists of instruments resembling guitars, and others like clarionets, with cymbals and kettle-drums, which altogether produce a very wild, but not an unpleasing, and a somewhat melancholy harmony. The women dance and sing; and when one is desired to dance, she calls for the ornaments of her feet, which consist of silver chains, which she fastens on her ancles. Then, rising from the ground, she arranges her dress, which generally consists of about a hundred yards of light muslin, which terminates in innumerable folds at about the swell of the leg; and of a shawl which covers part of the head, comes over the shoulders, and falls in folds over the petticoat. The hair is seldom ornamented, but is parted in the middle, and kept close down by the aid of the cocoa-nut, which improves its jet and gloss, but communicates an unpleasant odour. Behind the ears a bunch of pearls is worn like a cluster of grapes, and a ring is suspended from one of the nostrils, through which it is inserted. The ornaments however are sometimes more and sometimes less numerous and costly than this.

The dancing consists in a certain methodical kicking of the right foot, which causes the chains on the ancles to jingle in unison with the music; the dancer now advancing, then retreating; sometimes with the hands up, and twisting them about; at others, enveloping her head completely in the shawl. The movements of the bayadeer are sometimes so slow in this performance that an inexperienced spectator might suppose her about to fall asleep, when, in correspondence with a change in the music, she becomes full of life, and exhibits a rapid and exhausting succession of violent action. She takes up her robe and folds it into various shapes; then she lets it go, so that while she spins round like a top it forms a circle, bearing some resemblance to the tail of a peacock. It is perfectly amazing for what a length of time practice enables them to maintain this circular motion. This part of the performance is sometimes dispensed with. In different parts of the country these dances vary in the proprieties of dress and attitude. In some parts they are highly indecent, but this is not always, or perhaps generally, the case. The songs of the bayadeers however commonly express, in very warm language, the sentiments of amorous passion, as addressed by the female to her lover. Such songs afford a striking contrast to those of the Persians, who, according to Sir William Ouseley, "never suffer their females to make, either in prose or verse, any advances or declarations of love."

(Heber's *Narrative of a Journey, &c.*; Ouseley's *Travels in various Countries of the East.*)

BAYEUX TAPESTRY, a web or roll of linen cloth or canvass, preserved in the Hôtel de Ville, Bayeux, in Normandy, upon which a continuous representation of the events connected with the invasion and conquest of England by the Normans is worked in woollen thread of different colours, in the form of a sampler. It is 20 inches wide, and 214 feet long: and is divided into seventy-two compartments, each bearing a superscription in Latin which indicates its subject, or the person or persons represented. It is edged on its upper, as well as its lower part, by a border representing chiefly quadrupeds, birds, sphinxes, minotaurs, and other similar subjects. Mr. Bruce states that "it contains figures of 623 men, 202 horses, 55 dogs, 505 animals of various kinds not already enumerated, 37 buildings, 41 ships and boats, and 49 trees—in all 1512 figures."

Attention was first directed to this singular monument by M. Lancelot, in a memoir presented to the Academy of Inscriptions and Belles Lettres, in 1724, in consequence of his discovering an illuminated drawing from a portion of it, among the manuscripts in the library of M. Foucault, who had been Intendant of Normandy. At the time of finding it, he did not know what it actually represented; whether the original was a sculpture round the choir of a church, upon a tomb, or on a frieze; whether it was a painting in fresco, or on glass; or, lastly, whether it might not be a tapestry. He saw that it

was historical, and that it related to William Duke of Normandy and the conquest of England; and he wrote to Caen respecting it, but got no information.

Père Montfaucon, upon reading Lancelot's memoir, saw the value of this curious representation, and left no stone unturned till he had discovered the original. He wrote to Caen and Bayeux, and sent a copy of the drawing for inspection, when, at last, the canons of Bayeux recognised it as a portion of the tapestry in their possession, which tradition said had been worked by, or under the superintendence of, Matilda, the Conqueror's queen, which she had herself given to the cathedral, of which Odo, the Conqueror's half-brother, was bishop, and which they, the canons of Bayeux, were accustomed to exhibit to the inhabitants of the city, in the nave of their church, at a particular season of the year. M. Lancelot, in a second memoir, says it was at that time traditionally called *la Toile de Duc Guillaume*, a name by which it is still commonly known at Bayeux. Montfaucon sent an able artist, of the name of Antoine Benoit, to copy it; and at the opening of the second volume of his '*Monumens de la Monarchie Française*,' published in 1730, engraved the whole in a reduced form, accompanied with a commentary upon the Latin inscriptions, which, throughout, explain the intention of the figures represented in the different compartments.

M. Lancelot, upon the publication of the tapestry by Montfaucon, sent a second memoir to the Academy of Inscriptions and Belles Lettres (as has been just mentioned), which was read in 1730, and published in the same year, in the eighth volume of their transactions, in which he states that the earliest mention of this tapestry among the archives of the cathedral is in an inventory of jewels and ornaments belonging to the church, taken in 1476, where it is called "*une tente très longue et étroite de telle à broderie de ymages et escriptaux faisans representation du conquest d'Angleterre, laquelle est tendue environ la nef de l'Eglise le jour et par les octaves des reliques.*"

Dr. Ducarel is the next who gives us an account of this tapestry, in the appendix to his '*Anglo-Norman Antiquities*' (folio, London, 1767), where he has printed an elaborate description of it, which had been drawn up some years before, during a residence in Normandy, by Smart Lethieullier, Esq., an able English antiquary. Ducarel tells us that when he was in Normandy it was annually hung up on St. John's day, and went exactly round the nave of the church, where it continued eight days. At all other times it was carefully kept locked up in a strong wainscot press in a chapel on the south side of the cathedral.

From this time till the autumn of 1803 it received but little further notice, when Bonaparte, then first consul of France, contemplating the immediate invasion of England, ordered it to be brought from Bayeux to the National Museum at Paris, where it was deposited during some months for public inspection. The first consul himself went to see it, and affected to be struck with that particular part which represents Harold on his throne at the moment when he was alarmed at the appearance of a meteor which presaged his defeat,—affording an opportunity for the inference that the meteor which had then been lately seen in the south of France was the presage of a similar event. ('*Gentleman's Magazine*,' 1830, vol. lxi. pt. ii. p. 1136.) The exhibition was popular: so much so, that a small dramatic piece was got up at the Theatre du Vaudeville, entitled '*La Tapisserie de la reine Mathilde*,' in which Matilda, who had retired to her uncle Roger during the contest, was represented passing her time with her women in embroidering the exploits of her husband, never leaving their work, except to put up prayers for his success. (Millin, '*Magazin Encyclopédique*,' 1803, tom. iv. p. 541.) After having been exhibited in Paris, and in one or two large towns, the tapestry was returned to Bayeux, and lodged with the municipality. Mr. Dawson Turner, in his '*Tour in Normandy*,' written in 1818, says, the bishop and chapter of Bayeux had then recently applied to the government for the tapestry to be restored to their cathedral, but without effect. ('*Tour in Normandy*,' 8vo, Lond., 1820, vol. ii. p. 242.)

It was most fortunate that this curious monument escaped destruction during the Revolution. Its surrender at that time was demanded for the purpose of covering the guns; a priest however succeeded in concealing it and preserving it from destruction.

The new degree of publicity given to the tapestry by its exposure in the French capital again made it a subject of discussion; and the Abbé de la Rue, professor of history in the Academy of Caen, endeavoured, in a memoir, afterwards translated by Francis Douce, Esq., and printed in the 17th volume of the '*Archæologia*' of the Society of Antiquaries, to show that a mistake had been committed by tradition in the selection of the Matilda, and that its origin ought not to have been ascribed to Matilda the Conqueror's queen, but to Matilda the empress, the daughter of King Henry I.

The next memoir on this curious subject is comprised in a short letter from Mr. Hudson Gurney, printed in the 18th volume of the '*Archæologia*,' who saw the tapestry at Bayeux in 1814, where it then went by the appellation of the *Toile de St. Jean*, which is explained by what Ducarel has said, that it was formerly exhibited upon St. John's Day. Lancelot, Montfaucon, Ducarel, and De la Rue, appear all to have considered the tapestry as a monument of the Conquest of England, intended to have been continued to Duke William's coronation, but from some cause or other left unfinished. Mr. Gurney

considered it to be an apologetical history of the claims of William to the crown of England, and of the breach of faith and fall of Harold; and that, as it stands, it contains a perfect and finished action.

In the mean time, the Society of Antiquaries in 1816 despatched an excellent and accurate artist, Mr. Charles Stothard, to Bayeux, who, in that and the succeeding year, brought home a perfect fac-simile of the tapestry, the drawings of which have been since engraved, coloured like the original, and published in the 6th volume of the *Vetusta Monumenta*, plates i. to xvii.

The appearance of the first portion of Mr. Stothard's drawings gave rise to some Observations from Mr. Amyot, in refutation of an historical fact which the tapestry had been supposed to establish; namely, that of Harold's mission to Normandy by the Confessor to offer the succession to William. (*Archæol.* vol. xix. p. 88.) These were followed by C. Stothard's own observations while at Bayeux, pointing out such circumstances as presented themselves to his notice during the minute investigation to which the tapestry was necessarily subjected (*Ibid.* vol. xix. p. 184), and again followed by 'A Defence of the early antiquity of the Tapestry,' by Mr. Amyot (*Ibid.* p. 192), in which the objections raised by the Abbé de la Rue against the tradition which made the tapestry coeval with the events it celebrates, are completely invalidated.

The work begins with the figure of a king seated upon his throne, who is addressing one of two persons standing by his side: the inscription is simply 'EDWARD REX.' It appears to be Harold taking leave. We next see Harold proceeding to Bosham attended by several followers; he carries a hawk upon his fist, at that time the distinguishing mark of nobility; his dogs are running before him: 'IBI HAROLD DVX ANGLORVM ET SVI MILITES EQVITANT AD BOSHAM.' A church is then represented, in front of which are two men who appear about to enter: above is the word 'ECCLESIA.' This church is Bosham in Sussex. The party next appear feasting at a table in a house, previous to their embarkation. Some persons are descending the steps from the apartment where they have been dining; others are embarking in four vessels. Harold enters first, still bearing the hawk and carrying a dog under his arm. These last-mentioned figures are wading through the water, naked from the waist downwards: 'HIC HAROLD MARE NAVIGAVIT ET VELIS VENTO PLENIS VENIT IN TERRAM WIDONIS COMITIS.' The last of the four vessels next appears anchoring in France, Harold standing at the prow: his name 'HAROLD' above. Three figures are then represented upon land; one of them is Harold in the act of being seized by order of Guy Earl of Ponthieu, who is on horseback, followed by his people: 'HIC APPREHENDIT WIDO HAROLDVM ET DVXIT EVM AD BELREM ET IBI EVM TENVIT.' Harold and Guy are next seen mounted upon their horses, and attended both by Saxon and Norman soldiers. The Saxons are distinguished by wearing mustachios; the Normans have none. Harold and Guy appear in conversation, 'VBI HAROLD ET WIDO PARABOLANT:' when messengers arrive from William Duke of Normandy to the Earl of Ponthieu 'VBI NVNTII WILLELMI DVCIS VENERVNT AD WIDONEM.' Between the Earl of Ponthieu who is seated, and his guards who receive the messengers, a tree divides the subject, as other trees, in like manner, divide all the principal events throughout the work. A dwarf, with the name of 'TYROLD' above, holds the horses of Duke William's messengers. William's messengers are again represented on horseback, bearing shields; 'NVNTII WILLELMI.' Next is a Saxon messenger mustached, kneeling to William on his ducal seat: 'HIC VENIT NVNCIVS AD WILGELMVM DVCEM.' Guy is seen immediately after, conducting Harold to the duke: 'HIC WIDO ADDVXIT HAROLDVM AD WILGELMVM NORMANNO-RVM DVCEM.' William meets them, and returns with Harold to his palace: 'HIC DUX WILGELM CVM HAROLDO VENIT AD PALATIUM SVVM.' We have then a female figure within the door of a church, and a priest, and beneath them the words 'VNVS CLERICVS ET ÆLFGYVA.' Mr. Douce says evidently Adeliza, William's daughter, who was affianced to Harold. The next event is William's warfare with Conan Earl of Bretagne, in which it is apparent Harold assisted and rendered essential service to the Norman party: 'HIC WILLEM DVX ET EXERCITVS EIVS VENERVNT AD MONTEM MICHAELIS.' Soldiers, mounted on horseback, arrive at Mount St. Michael and pass the river Cosno: 'ET HIC TRANSIERVNT FLVMEN COSNONIS ET VENERVNT AD DOL.' Harold is depicted among them, assisting some persons who had fallen into the quicksands while passing the river: 'HIC HAROLD DVX TRAHÉBAT EOS DE ARENA.' We have then the words 'ET CONAN FVGA VERTIT.' Conan is seen escaping from Dol and descending the walls by a rope. Troops are flying and approach Rennes: 'REDNES.' The Norman soldiers are next employed in attacking Dinant: 'HIC MILITES WILLELMI DVCIS PVGNANT CONTRA DINANTES.' Conan delivers up to them the keys of the town, which they succeed in taking: 'ET CVNAN CLAVES PORREXIT.' After this event William rewards the services of Harold by giving him a suit of armour: 'HIC WILLELM DEDIT HAROLDO ARMA.' William and his party then arrive at Bayeux; 'HIC WILLELM VENIT BAGIAS.' It is said that William, in order to secure to himself the succession of the Saxon throne, without having Harold for a competitor, caused him to take a solemn vow that he would never attempt the possession of the English crown: this vow he obliged Harold (then within his power) to make upon a covered altar, beneath which William had placed the most sacred and precious relics. No sooner had Harold

sworn the oath, than the Norman duke uncovered the altar, and by showing him what sacred things he had vowed, enforced upon his mind the blasphemy he would be guilty of, if he ever attempted the violation of his oath. Harold is represented taking the oath, while standing between two covered altars: 'VBI HAROLD SACRAMENTVM FECIT WILLELMO DVCI.' Harold next embarks for England: 'HIC HAROLD DVX REVERSVS EST AD ANGLICAM TERRAM ET VENIT AD EDWARDVM REGEM;' and is immediately after represented as relating the events of his journey to the Saxon king.

The next subject is the death and funeral of Edward the Confessor. The funeral procession comes first: 'HIC PORTATVR CORPVS EADWARDI REGIS AD ECCLESIAM PETRI APOSTOLI.' The king is then represented in his bed, giving his last directions to the officers of his court: his wife Editha weeping by his side: 'HIC EADWARDVS REX ALLOQVIT FIDELIS.' Beneath he is represented dead and laid out: 'ET HIC DEFVNCTVS EST.' The next subject is the crown offered to Harold by the people: 'HIC DEDERVNT HAROLDO CORONAM REGIS.' Harold then appears upon his throne, Stigand, Archbishop of Canterbury, at his side: 'HIC RESIDET HAROLD REX ANGLORVM. STIGANT ARCHIEPISCOVVS.' The subject that follows is the appearance of a comet, at which the people are gazing: 'ISTI MIRANT STELLAM.' Harold is seen below it, listening to a person who has approached him: his name above, 'HAROLD.' Boats are represented in the border beneath. The next subject which the tapestry represents is a ship, bringing to William the news of Harold's having assumed the English crown: 'HIC NAVIS ANGLICA VENIT IN TERRAM WILLELMI DVCIS.' William and his half-brother, Odo, bishop of Bayeux (distinguishable by the tonsure), appear consulting together and giving orders that ships should be built for the purposed invasion of England: 'HIC WILLELM DVX IVSSIT NAVES EDIFICARE.' Accordingly several persons are next represented as employed in cutting down trees; carpenters are constructing vessels, and others draw them into the sea: 'HIC TRAHVNT NAVES AD MARE.' The embarkation of the Normans forms the succeeding subject; they carry with them on board the ships wine, arms, and provisions: 'ISTI PORTANT ARMAS AD NAVES ET TRAHVNT CARRVM CVM VINO ET ARMIS.' William going to his own vessel is next represented: 'HIC WILLELM DVX IN MAGNO NAVIGIO.' Numerous ships are then seen passing the sea, loaded with troops and horses, and William arrives in Pevensey bay (his own vessel known by the figure of a boy holding a pennon at the stern; it bears a lantern at the mast): 'MARE TRANSIVIT ET VENIT AD PEVENESE.' The troops and horses next appear disembarking: they proceed to Hastings, where they seize provisions: 'HIC EXEVNT CABALLI DE NAVIBVS ET HIC MILITES FESTINAVERVNT HASTINGA VT CIBVM RAPERENTVR.' A figure on horseback, bearing a pennon at the end of his lance, is here distinguished by the words 'HIC EST WADARD.' The Normans are now busied in cooking meats and regaling themselves: 'HIC COQVITVR CARO ET HIC MINISTRAVERVNT MINISTRI. HIC FECERVNT PRANDIVM.' The soldiers dine upon their shields. Odo seated at a table, with William on his right hand, bestows his benediction on the viands: 'ET HIC EPISCOVVS CIBVM ET POTVM BENEDICIT.' William, with Odo and Robert Earl of Mortaigne, are seated under a canopy: 'ODO EPISCOVVS. WILLELM. ROTBERTVS.' A figure carrying a pennon then appears giving orders that the army should encamp at Hastings: 'ISTE IVSSIT VT FODERETVR CASTELLVM AT HESTENGA.' The camp forming: 'CASTRA.' William appears directing the building of a castle. The news is then brought to William that Harold is advancing to oppose the Normans; William on a raised seat: 'HIC NVNTIATVM EST WILLELMO DE HAROLD.' Two Normans setting fire to a house; a woman and child escaping from it: 'HIC DOMVS INCENDITVR.' The soldiers of William leave Hastings to meet Harold in the field; and the duke now, for the first time since his arrival, appears in armour: the march of the horsemen: 'HIC MILITES EXIERVNT DE HESTENGA ET VENERVNT AD PRELIVM CONTRA HAROLDVM REGEM.' Odo is represented bearing a mace, but preceded by William on horseback with a club, who interrogates Vitalis, an individual of his army, also on horseback, whether he has seen Harold's forces: 'WILLELM DVX INTERROGAT VITAL. SI VIDISSET EXERCITVM HAROLDI.' Harold also receives information relative to William's force: 'ISTE NVNTIAT HAROLDVM DE EXERCITV WILLELMI DVCIS.' William then addresses his soldiers, who are proceeding onward to the battle: 'HIC WILLELM DVX ALLOQVITVR SVIS MILITIBVS VT PREPARARENT SE VIRILITER ET SAPIENTER AD PRELIVM CONTRA ANGLORVM EXERCITVM.' The Normans approach, mostly on horseback, but intermixed with archers on foot. The battle now ensues, in which the Saxons are chiefly on foot, their shields distinguished from those of the Normans by being usually round with a boss in the centre. Lewine and Gyrth, the brothers of Harold, are slain: 'HIC CECIDERVNT LEWINE ET GYRTH FRATRES HAROLDI REGIS.' The obstinacy of the contest is next represented: 'HIC CECIDERVNT SIMVL ANGLI ET FRANCI IN PRELIO.' Odo is now represented charging full speed and striking at a horseman with a club or mace: 'HIC ODO EPISCOVVS BACVLVM TENENS CONFORTAT PVEROS.' This probably means that Odo had to encourage the troops, upon a report that William was slain. The battle continues; 'HIC EST WILLELM DVX.' The duke appears showing himself and giving orders: 'HIC FRANCI PVGNANT ET CECIDERVNT QVI ERANT CVM HAROLDO.' The death of Harold, the standard carried before whom appears to be a dragon. We have then the discomfiture and flight of the Saxons. Here the tapestry ends with figures of persons retreating in great haste; not

complete in its ornamental work, but, in all probability, complete in its history.

This extraordinary piece of needle-work—for such it is, though called tapestry—is now preserved in the Hôtel de Ville at Bayeux. It used to be kept coiled round a machine, like that which lets down the buckets of a well, and exhibited by being drawn out at leisure over a table; but it is now kept under glass, in the public library. The coloured plates of it, published by the Society of Antiquaries, from the drawings of Mr. Charles Stothard, in the 4th volume of the 'Vetusta Monumenta,' will enable any one to form a very accurate notion of its actual appearance. Plates i. to xvi. represent the whole, one-fourth size of the original. The xviii. plate gives a portion of the true size. Dibdin, in his 'Bibliographical Tour,' vol. i. p. 377, has engraved a view of it upon its machine. Thierry, in the Atlas of Plates to his 'Histoire de la Conquête de l'Angleterre par les Normands, cinquième éd.' 1839, has engraved a reduced fac-simile of the tapestry. It has also been engraved on a reduced scale, in colours, from the plates in the 'Vetusta Monumenta,' in 'The Bayeux Tapestry Elucidated,' by J. C. Bruce, LL.D., 8vo, Lond., 1855, the latest and most complete work on the subject.

It was long since decided by the French antiquaries, that this work is of the age of the Conquest, the Abbé de la Rue alone maintaining that it was executed in the time of our Henry I. Those persons however among the English antiquaries whose particular learning and knowledge render them competent judges of the authenticity of this tapestry, unite in the conviction that its own internal evidence corroborates the ancient tradition which the French antiquaries adopted. It represents the minutest manners and customs of the earliest Norman times in England; and was evidently designed while the particulars of the contest were known and fresh in recollection. It embraces several events of which no other record now exists, amongst which may be noticed the taking of Dinant, and the war between the Duke of Normandy and Conan, earl of Bretagne. Nor does any other notice exist of the service rendered by Harold to Duke William, during his war in Brittany. It is not a little remarkable, too, that in the compartment which represents the funeral procession of Edward the Confessor, a figure is portrayed placing a weathercock upon the spire of Westminster Abbey, indicating that the building was scarcely finished at the time of his decease. Ducarel, as we have already mentioned, says, that this tapestry, when exhibited at Bayeux, went exactly round the nave of the church.

Odo, it is to be remarked, makes the most conspicuous appearance, next to Duke William, of any Norman personage represented in the tapestry; and three figures, *Wadard*, *Turolde*, and *Vital*, apparently unimportant personages, were really among the chief of those whom Odo brought into the field. *Wadard* and *Vitalis*, with the son of a person named *Turolde*, are recorded, twenty years after the Conquest, among the under-tenants of Odo, as persons rewarded with lands, in the Domesday Survey. *Wadard* held property under the bishop in no fewer than six counties; *Vitalis* held lands under Odo in Kent; and the son of *Turolde* in Essex. (Ellis's 'Introduction and Indices to Domesday,' vol. ii. p. 403.) These circumstances cannot but appear convincing, not only that the tapestry is of the age assigned to it by tradition, and was worked expressly for the bishop's cathedral, but render it very probable that it was a present from Matilda, the Conqueror's queen, as a grateful memorial of the effective service which Odo had rendered in the Conquest.

BAYONET. [ARMS.]

BAZAAR. The word *bazaar* is Persian, and its primary meaning is a market, a forum. In Turkey, Egypt, Persia, and India this term distinguishes those parts of towns which are exclusively appropriated to trade. In this exclusive appropriation they resemble our markets; but in other respects they approximate more nearly to our retail shops. We have interpreted the word in its large sense; for although the term *bazaar* is in this country commonly understood to mean an assemblage of shops or stalls under cover, yet in fact it equally applies to open places in which bulky commodities are offered for sale. Such places sometimes occur in eastern towns, and are used chiefly in the early morning, at least in summer, for the sale of vegetables and cattle. If a place in the open ground outside a town be commonly applied to this use, it will be called a bazaar, and will be distinguished, as in all other cases, by joining to the word "bazaar" the name of the commodity sold. In large towns, however, such markets are generally near or in the midst of the regular covered bazaars; except the market for cattle, which is always outside or at the extremity of the town. In some places bazaars are rather extensive squares, the sides of which are lined with shops under arcades. In a few cases the covered ways branch off with some regularity from these squares as from a centre: and in one of the best specimens of the open market, at Kermanshah in Persia, the palace of the prince-governor occupies one of its sides. When, however, as in this and some other instances, the principal open area in the city is thus appropriated, its distinctive appellation of the *Maidan*, or square, is retained.

The regular bazaars consist of a connected series of streets and lanes, and, when of a superior description, they are vaulted with high brick roofs. The domes or cupolas which surmount the vaulting admit a subdued daylight; and, as all direct rays of the sun are excluded, a comparatively low temperature is obtained. The description

of a good bazaar in Persia is a description of a good bazaar in Turkey or India. Nevertheless, the Persian bazaars are rather more light and lively than those of Turkey. They are painted in many places, and sometimes decorated, particularly under the domes, with portraits of the heroes of the country, with representations of battles or hunts, with figures of real or fabulous animals, and with other subjects. The approaches to the bazaars are commonly lined with low shops, in which commodities of little value are exposed for sale. These approaches are sometimes open to the sky; but they are more generally covered in a rude manner with branches of trees, and leaves laid upon beams. In many of the provincial towns of Turkey and Persia, the bazaar, as a whole, would answer to this last description; and in others it is nothing more than a mud platform continued along the wayside, about two feet above the footpath, on which little covered shops are raised, that are mere boxes, scarcely affording room for the vendor to sit down on a bit of carpet or felt in the midst of his scanty stock.

In the best specimens of the vaulted bazaar the passages are lined on each side with a uniform series of shops, the floor of which is a platform raised from two to three feet above the level of the ground, and faced with brick. As the vault springs from the front of the line of shops, they seem like a series of recesses, and the partition-walls between them appear like piers supporting the arch. These recesses are entirely open in front, in all their height and breadth; they are scarcely more than very small closets, seldom exceeding six feet in breadth, rarely so deep as wide, but generally from eight to ten feet in height, and occasionally more. But in the more respectable parts of large bazaars there is generally a little door in the back wall which conducts to another small and dark closet, which serves the purpose of a store-room. The front cell is the shop, on the floor of which the master sits with his goods all around him, the articles most in demand being placed so within his reach that he has seldom occasion to rise, which, if he is a Turk, he rarely does without manifest reluctance. Such a dealer offers a very singular contrast to our ideas of a shopkeeper, being the very personification of luxurious repose as he sits smoking his pipe; or, if in winter, when these berths are chilly and uncomfortable, bending over a brazier of burning charcoal. The neighbouring shopkeepers have much communication with one another, and generally exhibit as much alacrity in promoting the interest of a neighbour as can be compatible with attention to their own. Indeed, a stranger might be disposed to imagine that all the tradesmen in the same line of business are in a general partnership, so little anxiety does any one exhibit to obtain a preference, and so willingly does he inform a customer where he may obtain an article more exactly suited to his wants than he can himself supply. This is more apparent in Turkey than in Persia. Persian, Armenian, and Jewish shopkeepers are in general more civil and obliging than Turks, and exhibit more anxiety to obtain custom. The writer has often been constrained by the former to turn aside and smoke of their pipes, and eat of their onions and bread, without being directly urged to make any purchase; but it is more pleasant to deal with a Turk, though he would not do this, because he deserves more confidence, yet not implicit confidence, in matters of purchase and sale. A French writer (M. Aubert de Vitry) says, "It is not necessary to offer a Turk less than two-thirds of the price he demands; to a shopkeeper of any other nation one-half may be safely offered; and in the case of the Jews there is no limit to the abatement." This is perfectly true; and no stranger in the East could have a better rule for his guidance in such matters.

Business commences and terminates with daylight in oriental bazaars. No trade or handicraft employment is in general carried on in the East by candle-light. None of the shopkeepers or artisans reside in the bazaars. When it gets dark, every one shuts up his shop and goes home. The fastenings of the shops are very slight; but the bazaars are in general well watched, and frequently secured with strong gates. In very warm countries it is usual for the majority of the shopkeepers to close their shops at mid-day, and go home to have their lunch and enjoy a siesta. The bazaars have then a very deserted appearance. Larcenies in the bazaars are scarcely known in Turkey; hence the shopkeepers do not hesitate to leave their shops quite open, without any one in charge, during their occasional absences; but when a rather long absence is intended, and the goods are of great value, a net, like a cabbage-net, is sometimes hung up in front, or laid over the goods.

The peculiar principle of oriental bazaars is, that all the shops of a city are there collected, instead of being dispersed in different streets as in Europe, and that in this collected form the different trades and occupations are severally associated in different parts of the bazaar, instead of being indiscriminately mingled as in our streets. Thus, one passage of the bazaar will be exclusively occupied by drapers, another by tailors, another by cap-makers, another by saddlers, and so on. In the bazaars of Persia, and, although less usually, in those of Turkey, the shops of provisions for immediate use form an exception to the rule. The shops of cooks and bakers are dispersed in different parts of the bazaar; the preparations in the former seldom extend beyond soups, and a sort of sausage without skin, called *kabooob*, a highly-seasoned and savoury article, which is much relished both in Turkey and Persia. Not only are trades carried on, but handicraft employments are exercised in the bazaars of the East; and thus while one part is very quiet, another resounds with the hammers of carpenters, smiths, and shoemakers. The stocks of the individual dealers are seldom of much

value; but an imposing effect is produced by the exhibition of the several stocks in a connected form, so that the whole of a particular street in a bazaar will appear as one great shop for the article in which it deals. This is the cause of the reported splendour and riches of an oriental bazaar. Of this kind of effect the bazaar for ladies' slippers in Constantinople is a very remarkable instance; such an extensive display on each side, through a long covered street, of small slippers, resplendent with gold and silver embroidery, and silk, and coloured stones, conveys an impression of wealth, luxury, and populousness which ten times the

number of shops in a dispersed form would not give. Wholesale dealers have no open shops in the bazaars, but they have warehouses in it or in its vicinity, to which the retailers resort as they have occasion. These warehouses are frequently in a large house or khan, occupied in common by several wholesale dealers. The khans also, to which the itinerant merchants resort until they have disposed of their goods, are generally in or near the bazaars; and they frequently make use of the same building with the stationary merchants.

Besides the regular business conducted in the bazaars by the pro-

[Turkish Bazaar, from the French work on Egypt.]

fessional shopkeepers, there is an under-current of irregular trade, highly characteristic of oriental manners. If a person not in business, or a stranger, has an article of which he wishes to dispose, he employs a crier, who takes it through the bazaar, proclaiming at the top of his voice its praises and its price. Many poor people also endeavour in the same manner, without the services of the crier, to dispose of such articles of their property, or produce of their industry, as they desire to sell. These are mostly persons who imagine they shall be able to obtain a better price from the purchasers or idlers in the bazaar than they have found the shopkeepers willing to give. There is also a class of sellers who exhibit a little stock of wares upon stools, in baskets, or on cloths spread on the ground. They generally deal in but one commodity, which they profess to sell on lower terms than the shopkeepers will take. It would seem that in respectable towns a preference is given to this mode of selling some one particular commodity. Much tobacco, and most of the little snuff that is used, are sold in this way at Bagdad; much opium is thus disposed of every morning at Tabreez in Persia; and at Constantinople many women post themselves in the bazaars, displaying embroidered handkerchiefs and other needlework, often wrought by the hands of ladies of quality, who are enabled by the produce to make a private purse for themselves, and purchase some little indulgences which they might not otherwise obtain.

In hot weather, oriental bazaars are traversed by men laden with a

skin or pitcher, from which they deal out to the thirsty a draught of excellently filtered water. Sometimes payment, seldom exceeding the fourth of a farthing, is expected; but frequently the men are employed to distribute water gratuitously, by pious individuals, who consider it an act of charity acceptable to Allah.

The contrast between the deserted appearance of the streets in an oriental town and the thronged state of the bazaars surprises a stranger. The women, except those of the lowest class, go little abroad; and of the men, the idle resort to the bazaar for amusement or conversation; and those who are not idle generally have some business there in the course of the day, which collects the visible population much into that part of the town, until the approach of evening effects a more equal distribution. The bazaar is not only the seat of immediate traffic, but of all commercial business; there all public, mercantile, and private news circulates, and there only free discussion can be carried on, unrestrained by the presence of the emissaries of power who haunt the coffee-houses. Public measures are keenly investigated, and the popular voice is often loudly expressed even to the ears of princes or ministers if they appear in the bazaars, as they sometimes do. Through the medium of slaves, eunuchs, and other agents, a constant intercourse is maintained between the innermost recesses of the seraglio and the bazaar. This is particularly the case at Constantinople, and in the capitals of the Turkish pashalics, and it is doubtful whether any thing

is transacted in the palaces at night, which is not known in the bazaars the next morning. This intercourse has often exercised an influence upon public affairs which none but the most minute inquirers into oriental history would suspect.

The various characteristic displays of oriental manners which the bazaars furnish, the nature of the goods exposed for sale, and the splendid appearance they sometimes make, the manner in which the artisans conduct their various labours, the endless variety of picturesque costumes which meet the eye, and the Babel-like confusion of tongues, all combine to form a scene of unequalled singularity and interest. No traveller who does not, in some oriental costume, sedulously frequent the bazaars and make many little purchases for himself, ought to feel assured that he understands the people, or has materials for fairly estimating their condition. The remarks here made are the result of the writer's intimate personal acquaintance with the bazaars of the East.

In this country the term bazaar is chiefly applied to large buildings, in which are arranged counters for the display and sale of articles of ornament, millinery, jewellery, toys, &c. They chiefly differ from arcades in not having distinct shops. [ARCADE.] These bazaars are of very recent date; the Soho Bazaar, the oldest establishment of the kind in the metropolis, having been founded in 1815. But the modern bazaar scarcely differs from the old Royal Exchange, and Exeter 'Change in the Strand, so often spoken of in the lighter literature of the latter part of the 17th, and early part of the 18th centuries. Besides the Soho Bazaar, there are in London the Pantheon, in Oxford Street; the Portland Bazaar, Langham Place; the London Crystal Palace, Portland Street, Oxford Street; the Pantechnicon, Pimlico; and the Baker Street Bazaar, near Portman Square. The two last, however, differ from the other bazaars in being places for the sale of carriages, furniture, pianofortes, and other heavy goods. Bazaars for the sale of light fancy goods, toys, &c., of a similar description to the London bazaars, have also been established in many of the larger towns and watering-places in various parts of the country.

On the continent, the bazaar is sometimes a market-place; sometimes, as at Antwerp, an Exchange combined with a place for the display and sale of articles of luxury, or a bazaar in our ordinary acceptance of the term.

BDELLIUM. Two resinous substances have both received this name. One is the *Indian Bdelium*, or *false myrrh*, and is obtained from the *Amyris Commiphora*. It is the bdelium of Scripture. The other is termed *African Bdelium*, and is produced from the plant *Hendolotia Africana*, a native of Senegal. The Indian bdelium is very similar to myrrh, and the tree which produces it diffuses a grateful fragrance to some distance around it. The African bdelium is much less odoriferous; it occurs in rounded or oval masses, from one to two inches in diameter, and has a dull wax-like fracture. According to Pelletier, it consists of

Resin	59.0
Soluble gum	9.2
Bassorin	30.6
Essential oil and loss	1.2
	100.0

Johnston gives the formula $C_{40}H_{31}O_5$ for bdelium (African?).

BDELLIUM, Medical uses of. Resembling myrrh in appearance, it also resembles it in its effects upon the human system, and is often fraudulently substituted for it; it is, however, weaker, while it is more disagreeable and acrid. [BALSAMODENDRON.] It was formerly used in many compounds and plasters, such as *diachylon*. It is now disused in Britain; but is to be found intermixed with gum Arabic.

The bdelium mentioned in the second chapter of Genesis has been supposed to mean *pearls*.

BEACON, a sign or token ordinarily raised upon some foreland or high ground as a sea mark. It is also used for the fire-signal which was formerly set up to alarm the interior of the country upon the approach of a foreign enemy. The word, as used in England, is derived from the Anglo-Saxon beacen or beacn, a sign or signal, whence bycnian, to show or point out. *Beac* or *bec* is the real root, which we still have in *beck*, *beckon*.

Fires by night, as signals, to convey the notice of impending danger to distant places with the greatest expedition, have been used in almost all countries. They are mentioned in the prophecies of Jeremiah, who (chap. vi. v. i.) says, "Set up a sign of fire in Beth-haccerem, for evil appeareth out of the north, and great destruction." Æschylus, in his play of the 'Agamemnon,' represents the intelligence of the capture of Troy as conveyed to the Peloponnesus by fire-beacons.

Lord Coke, in his 'Fourth Institute,' chap. xxv., speaking of our own beacons, says, "Before the reign of Edward III. they were but stacks of wood set up on high places, which were fired when the coming of enemies was descried; but in his reign pitch-boxes, as now they be, were, instead of those stacks, set up; and this properly is a beacon." These beacons had watches regularly kept at them, and horsemen called hobbelaers were stationed by most of them to give notice in day-time of an enemy's approach, when the fire would not be seen. (Camd. 'Brit.' in 'Hampshire,' edit. 1789, vol. i. p. 173.)

The Cottonian manuscript in the British Museum, Augustus I., vol. i. art. 31, preserves a plan of the harbours of Poole, Purbeck, &c., followed (art. 33) by a chart of the coast of Dorsetshire from Lyme to

Weymouth, both exhibiting the beacons which were erected on the Dorsetshire coast against the Spanish invasion in 1588. Art. 58 preserves a similar chart of the coast of Suffolk from Orwell Haven to Gorleston, near Yarmouth, with the several forts and beacons erected on that coast.

The power of erecting beacons was originally in the king, and was usually delegated to the lord high admiral. In the eighth of Elizabeth an Act passed touching sea marks and mariners (chap. 13), by which the corporation of the Trinity House of Deptford Strond were empowered to erect beacons and sea-marks on the shores, forelands, &c., of the country according to their discretion, and to continue and renew the same at the cost of the corporation.

Professor Ward, in his 'Observations on the Antiquity and Use of Beacons in England' ('Archæologia,' vol. i. p. 4), says, the money due or payable for the maintenance of beacons was called *Beconagium*, and was levied by the sheriff of the county upon each hundred, as appears by an ordinance in manuscript for the county of Norfolk, issued to Robert de Monte and Thomas de Bardolfe, who sat in Parliament as barons, 14th Edward II.

The manner of watching the beacons, particularly upon the coast, in the time of Queen Elizabeth, may be gathered from the instructions of two contemporary manuscripts printed in the 'Archæologia,' vol. viii. pp. 100, 183. The surprise of those by the sea-side was usually a matter of policy with an invading enemy, to prevent the alarm of an arrival from being spread.

An iron beacon or fire-pot may still be seen standing upon the tower of Hadley Church in Middlesex. Gough, in his edition of Camden, fol. 1789, vol. iii. p. 281, says, "at Ingleborough, in Yorkshire, on the west edge, are remains of a beacon, ascended to by a flight of steps, and ruins of a watch-house." Collinson, in his 'History of Somersetshire,' 4to, 1791, vol. ii. p. 5, describes the fire-hearths of four large beacons as remaining in his time upon a hill called Dunkery Beacon in that county. He also mentions the remains of a watch-house for a beacon at Dundry (vol. ii. p. 105). Beacon-hills occur in some part or other of most counties of England which have elevated ground. The Herefordshire beacon is well known. Gough, in his additions to Camden, ut supr. vol. i. p. 394, mentions a beacon hill at Harescombe in Gloucestershire, inclosed by a transverse vallation 50 feet deep. Salmon, in his 'History of Hertfordshire,' p. 349, says, at Therfield, on a hill west of the church, stood one of the four beacons of this county.

BEACON. [LIGHT-HOUSE.]

BEAD-MOULDING. [MOULDINGS.]

BEADLE, the messenger or apparitor of a court, who cites persons to appear to what is alleged against them. It is probably in this sense that we are to understand the *bedelli*, or under-bailiffs of manors mentioned in several parts of the 'Domesday Survey.' Spelman, Somner, and Watts, all agree in the derivation of beadle from the Saxon bydel, a cryer, and that from bidd, to publish, as in bidding the banns of matrimony. The bedelli of manors probably acted as criers in the lord's court. The beadle of a forest, as Lord Coke informs us in his Fourth Institute, was an officer who not only warned the forest courts and executed process, but made all proclamations.

Bishop Kennett, in the Glossary to his 'Parochial Antiquities of Oxfordshire,' says that rural deans had formerly their beades to cite the clergy and church officers to visitations and execute the orders of the court Christian. Parochial and church beades were probably in their origin persons of this description, though now employed in more menial services.

Bedel, or beadle, is also the name of an officer in the English universities, who in processions, &c., precedes the chancellor or vice-chancellor, bearing a mace. In Oxford there are two esquire and three yeomen bedels, each attached to the respective faculties of divinity, medicine and arts, and law. In Cambridge there are three esquire bedels and one yeoman bedel. The esquire bedels in the latter university, beside attending the vice-chancellor on public solemnities, attend also the professors and respondents, collect fines and penalties, and summon to the chancellor's court all members of the senate.

BEADS. The manufacture of glass beads is carried on in the following manner, at Murano near Venice. Tubes of glass of various colours are drawn out to great length, in a gallery adjoining the glass house; in the same way as barometer and thermometer tubes are drawn out in an English glass house. The tubes are then cut into very small pieces of nearly uniform length, on the edge of a fixed chisel. These small pieces are put in a heap into a mixture of fine sand and wood ashes, and stirred about with an iron spatula till their cavities get filled. The mixture is transferred to an iron pan suspended over a moderate fire and continually stirred until the cylindrical bits assume a smooth rounded form. When removed from the fire, and cleared out in the bore, they constitute beads.

Foreign beads are imported to the value of 8000*l.* to 10,000*l.* annually.

Beads are also made to an enormous extent in Birmingham; where certain varieties of them are sold in thousands of dozens for *dolls' eyes*.

Beads were used as ornaments, both as necklaces and armlets, from a very remote period. In 1839, on removing parts of a barrow at Northwold in Norfolk, there were found sixty-five beads of dark blue glass, rock crystal, and vitrified paste, cut in facets, and which most likely had formed the necklace of an Anglo-Saxon lady. About

1851, there was found a number of beads at Donaghadee, in the county of Down, Ireland; 150 glass beads were found, of various colours, with spiral ornaments in yellow enamel, with several others of amber. They were of various sizes, and probably also formed a necklace. From the bronze articles found with them there is little doubt that they are Roman, though, as the Romans had no settlement in Ireland, it is not easy to say how they came there. ('Archæological Journal' for 1856.)

BEADS (Rosary) are made of horn, ebony, ivory, glass, boxwood, and other materials, and are strung in chaplets used by the Roman Catholics for the purpose of counting their prayers. The Rosary is a series of prayers said to have been first instituted by St. Dominic about the year 1200, in honour of the Virgin Mary, and as an invocation to her for spiritual assistance. It consists of a repetition of the Ave Maria and the Paternoster or Lord's Prayer, both in Latin. It is divided into decads of ten Ave Marias, each decad being preceded by the Lord's Prayer, and terminating with the Gloria Patri. The full or great rosary consists of fifteen decads, but the common rosary, which is recited generally in the evening by pious Catholics, consists of only five decads. At the end of the five decads they recite the Creed, or Symbol of the apostles, and afterwards (in Italy at least) the Litany of the Virgin, which is different from the Litany of the Liturgy. The rosary is a daily family evening prayer; the head of the family says the first part of each Ave Maria, and the other members repeat in chorus the remaining part. [AVE MARIA.] "The original rosary of St. Dominic is a recitation of fifteen decads of Ave Marias, preceded each by a Pater, each decad being devoted to the meditation of one of the mysteries of the life of our Saviour. The first five mysteries are those of the incarnation, nativity, &c., and are styled joyful mysteries. The next five are those of the passion and death, and are styled sorrowful. The remaining five are those of the resurrection, ascension, assumption of the Virgin, &c., and are termed glorious." (Touren, 'Vie de St. Dominic'; 'Quindecim Mystera Rosarii Beatæ Mariæ Virginis,' a R. Schiaminasso delin. atque incisa, Rome, 1609.) The common chaplet is called *Corona*, "a crown," in honour of the Virgin.

The beads are distinguished by their size and shape, those marking the Lord's Prayer being larger than those for the Ave Marias. Rosaries of very small glass beads are worn by pious Catholics round their necks. The object of St. Dominic was probably, while doing honour to the Virgin, to fix at the same time the attention of the pious on the contemplation of the principal events of the Saviour's life, by allowing a certain time, marked by the recitation of ten Ave Marias, to the meditation upon each event or mystery. The name of rosary is figurative: it means a chaplet of spiritual roses, divided into three sets, white, red, and damask roses, corresponding to the joyful, sorrowful, and glorious mysteries. Such are the allegory and its explanation. ('The Rosarie of our Ladie otherwise called our Ladie's Psalter,' Antwerp, 1600.)

The Turks and other eastern nations have also chaplets of beads made of amber or other materials, which they turn through their fingers while sitting in a listless mood, but not, as it seems, for any purpose of prayer. The Turkish chaplet is called "Comboloio." The Chinese rosary consists of 108 beads of stones and coral, sometimes as large as pigeons' eggs, and is a part of the ceremonial dress, worn as a necklace and descending to the waist with certain beads introduced to mark the rank of the wearer. A smaller rosary of eighteen beads is used by the bonzes and the laity.

BEAMS. [MATERIALS, STRENGTH OF.]

BEAN, THE. Of this leguminous plant many varieties, classed however under only one species botanically, are extensively cultivated in the garden and in the field. It is the *Faba vulgaris* or *Vicia Faba*, which is our common garden and field bean. The French bean, haricot, or kidney-bean is an altogether different plant—*Phaseolus vulgaris*. We here consider them only from the agricultural point of view.

The common bean bears a pod containing several oblong rounded seeds, which are used in the soft young state for the table, and in the hard dry state for domestic animals chiefly, either whole or ground into meal. In some places bean-meal is mixed with other meal in making coarse bread; or the beans are boiled into a mess with fat meat, in which state they are very palatable and nutritious. The bean came originally from the east, and was cultivated in Egypt and Barbary in the earliest ages of which we have any records. It spread thence into Spain and Portugal, from whence some of the best varieties have been introduced into this country. The most common varieties of the garden beans are the Windsor, the Toker, the long-pod, and the Mazagan, all productive and well-tasted. In the field the tick bean, the common horse bean, the winter bean, and the small Dutch, or Heligoland bean, are preferred, being hardy as well as productive. The long-pod is occasionally sown in the field, the Mazagan and broad Windsor bean seldom.

There is no plant in which the transformation of the cotyledons into seed leaves is more readily traced than in the bean. The Windsor bean, in particular, from the size of its lobes and distinctness of its vessels, is admirably adapted for observation, the parts being readily distinguished by the naked eye. If a bean is planted in moist earth or soaked in water, in a moderate temperature, the cotyledons will swell and soon burst the skin which envelops them, separating into two lobes, which open like the shells of an oyster. In the part which forms

the joint an oblong body will appear, which is the embryo stem of the plant. This increases rapidly in the earth, and pushes a root downwards, and a stem upwards, which latter carries the lobes with it till they rise above the ground, when they expand, and are transformed into seed leaves. It is curious to observe the force of vegetation in the young bean when it is, as it were, imprisoned in a strong soil hardened at the surface, as may be seen when a path crosses a field of beans newly planted; the cotyledons, under these circumstances, are drawn into the crevices made by the young stem, where they often remain held fast till the first shower releases them. The change in the cotyledons deserves particular attention. As soon as the seed swells by imbibing moisture, the oxygen, which is always present in the atmosphere and in water, acts upon the farinaceous substance in the seed, and takes a portion of carbon from it producing carbonic acid, which is absorbed by the surrounding plants, or flies off in the state of gas: by this loss the remaining substance becomes a mild fluid emulsion, analogous to the milk of animals, which, being taken up by the minute vessels of the radicle, nourishes and increases them. It is this alone which produces the first growth; the earth is the mere cradle to protect the young plant and to keep it moist, by preventing the too rapid evaporation which the heat and light of the sun would otherwise produce: when the ground is entirely deprived of moisture, vegetation necessarily ceases. The cotyledons are the reservoirs of nature to supply proper food for the plant in its infant state. In proportion as the farina in the lobes is gradually exhausted new vessels appear through the substance of the lobes, conveying the newly formed juice from every part of them into the root and stem, and, at last, the cotyledons are transformed into seed leaves. The fibres of the roots are by this time completely formed, and have acquired the power of absorbing nourishment from the soil. [ROOT.] The plant may now be said to be weaned. The stem is then considerably advanced in growth, having put forth new leaves of a different form from the seed leaves: these last, having now performed their part, wither and soon fall off; if they are removed before this period, the plant, having lost its nurse, languishes and dies.

The bean at this stage of its growth requires particular attention. If the soil is rich and well prepared, it will grow rapidly and luxuriantly, and be soon out of reach of insects or weeds, and capable of resisting or of turning to account the varying influences of the atmosphere; but if the soil is poor and parched, and the supply of nutritive juices is scanty, the plant will soon show weakness and disease, and the only way to prevent a total failure of the crop, is to supply by art the deficiency of nature. In very poor soils manure may be applied in a liquid state, or as a top-dressing: in those which are not exhausted, tillage alone will enable the roots to spread, and give them a wider range to seek their food in. The weeds being destroyed, the whole powers of the soil are reserved for the crop; and the air charged with fertilising vapours being allowed to penetrate the surface, and being retained in the interstices of the soil, greatly assists in invigorating the vegetation. These are the principles on which is founded the whole culture of leguminous plants, whether in the garden or the field. Where labour is not spared and the produce is valuable, and where vegetables are raised as a kind of luxury for the tables of the rich, the greatest attention is paid to the cultivation of beans, so as to have them early and in regular succession during the whole summer. They are even occasionally raised by artificial heat. In general they are sown or planted at various times, from the beginning of winter to the middle of summer, but they must be protected from frost in the first case, and from too great heat and drought in the latter. They are set in rows with wide intervals, which are kept dug and clean, and in which lesser vegetables are advancing in growth, to be sheltered by the beans, and to succeed them when removed. In order to strengthen the pods already formed, as soon as those which are near the bottom of the stem are filled, the tops of the plants are cut off, and the beans are gathered when the seed has acquired sufficient consistency to be taken from the shells, before they have acquired any farinaceous qualities. One crop is made to succeed another by regulating the times of sowing; and thus beans are gathered for the table from May to November, or till the frosty nights check the growth of the plant. The cultivation of the field bean is only as perfect an imitation of the garden culture as circumstances will permit. As only one crop is required, and that in a perfectly ripe state, when the seeds are fully formed and hard, they are sown at one particular season, so as to avoid the danger from frosts and ungenial weather in spring, and at the same time to have the crop ripe in good time to be harvested before the cold and wet season sets in. The usual mode is to drill them by a machine, at the distance of from twenty to thirty inches, according to the richness of the soil, or to dibble them by hand, either singly or by putting two or three beans in each hole, increasing the distance of the holes from six to twelve inches. Beans are tolerably hardy, and will bear moderate dry frosts; but they suffer much from alternate frosts and thaws, which in this climate are so common in February. The end of February, or the beginning of March, is therefore generally preferred for bean-sowing. When the season is remarkably mild, as was the case in 1834, early sowing is a great advantage. The writer of this article planted a field of beans on the 1st of January, 1834, in a soil duly prepared; they were reaped in August, and produced a very good crop: his neighbours, who planted their beans in March, had not half the quantity on equally

good land, owing to the dryness of the summer. But this was an experiment which succeeded: had severe weather come on in February, the whole crop might have been lost. As a general rule, beans may be sown from the middle of February to the middle of March. The sorts usually cultivated in the fields are the winter bean, the tick bean, the horse bean, and the small Dutch or Heligoland bean. In some situations the Mazagan and the long-pod have produced good crops in the field; the first four are however best suited for general cultivation. There are several varieties of these, which differ but little in their appearance; experience is the best guide in choosing the seed which suits particular soils and situations. The small round regular-shaped beans are generally preferred, as obtaining the best prices in the markets, especially in large towns, where there is a great consumption of beans by hard-working horses.

The soil best adapted for beans is a rich strong loam, such as produces good wheat. In such a soil the produce is sometimes fifty or sixty bushels per acre, but an average crop, on moderate land, is about half that quantity. On very rich land beans have produced extraordinary crops, by being sown broad-cast and very thick, the stems being drawn up to a great height in favourable seasons. A small field of very rich land, in the county of Sussex, was sown in the year 1832 with four bushels of the small tick bean, which came up so thick, that the proprietor thought of thinning out the plants by hoeing; but he was advised to see what the produce would be, and when they were threshed out, there were 10 quarters and 1 bushel of beans. He had the ground accurately measured, and it was found to be 1 acre and 29 perches, which makes the crop above 68 bushels per acre. They completely smothered all weeds, and the subsequent crop of wheat produced 5 quarters to the acre; but this particular example of sowing beans broad-cast we do not hold up for general imitation. By cultivating the beans in rows, and by careful hoeing and manuring, alternate crops of wheat and beans may be raised for many years, without intermission, or any necessity for change or fallow: this has been long the practice in the richest part of Kent. In this case the beans must be drilled or set in rows, with intervals of from 24 to 30 inches between the rows; and the intervals must be repeatedly stirred or hoed with proper instruments, so as to prevent the growth of weeds and keep the soil in a perfectly clean and mellow state; the weeds which rise in the rows are removed by hand. Immediately after bean harvest, the land is scarified, or skimmed over with a plough having a very broad share, whence the operation is sometimes called *broad-sharing*. All roots of weeds and the remains of bean-halm are collected and burned, or put in a heap with quicklime, to be converted into manure. The ground is then ploughed once or several times, according to circumstances, and wheat is sown about the month of October, either broadcast or by means of a drilling-machine, in rows 10 or 12 inches asunder, which gives greater facility for hoeing and weeding the crop when necessary. The wheat which follows beans is generally good and heavy, and seldom runs to straw. After wheat-harvest the stubble is ploughed up and turned in with a very deep furrow; the land is harrowed flat, and a good coating of manure is put on in a moderately rotten state, and this is covered with a shallow ploughing: the land is well water-furrowed and left so till spring, when the beans are drilled in the mellow surface produced by the winter's frost. This is the most approved practice; but many experienced farmers vary it according to the varieties of soil, or according to difference of opinion. Some put on manure for the beans in spring, and some drill the beans in every second or third furrow after the plough; but all good farmers agree in manuring the land for the beans and carefully hoeing them. It is evident that a different method is required in different soils, varied according to their texture and situation. Alternate crops of wheat and beans can only succeed, for any length of time, on soils peculiarly favoured. In general, a change of crops and occasional fallows will be indispensable to keep the land perfectly clean and in good heart.

In cold wet soils beans require great care to ensure good crops. Although they will grow well and seem to flourish in the stiffest and most unsubdued clays, they will seldom produce much at harvest, unless the land has been well prepared and the cultivation managed with skill. There is no better criterion of the experience and industry of the farmer of cold wet clays than the appearance of his beans at harvest; and he may be judged by this crop, as the farmer of light sandy soils may be judged by his turnips. The cultivation of these two opposite kinds of inferior soils will, in general, be profitable or otherwise in proportion to the produce of the beans in the one and the turnips in the other; the first being a substitute for clean fallow, and the latter the foundation of all the succeeding crops. The bean, by its strong and penetrating root, opens the stiff soil to the influence of the atmosphere, by which the surface is dried and at the same time mellowed. Although the nutritious matter in a good crop of beans is great, and almost equal to that obtained from a crop of wheat, it exhausts the soil much less: its succulent stems and leaves absorb much nourishment from the atmosphere, and the latter falling off and decaying, restore carbon and mucilage to the soil, and make up for the inferior quantity of manure produced by the bean-halm in comparison with wheat-straw. There is perhaps no crop, bearing seed, which gives so great a return with so small an expenditure of the fertility of the soil; and certainly none that repays manure better, or leaves the land in a better condition for wheat or oats. It is a very common practice

to plough a stiff soil in spring only once, after it has borne clover, grasses, or wheat, and to drill beans in the furrows immediately after the plough, by hand or by an instrument; in this case it is best to deposit the beans as near the angle of the furrow as possible, and in every second furrow only, that they may rise regularly at a proper distance. In spite of the tough slices which the plough turns over in a mass, the force of vegetation in the bean makes it pierce through them, and, under favourable circumstances, a tolerable crop is sometimes obtained; while the more industrious neighbour, who has tilled his land in autumn and again in spring, by repeated ploughings, and made it fine and mellow, may be disappointed in his crop by untoward variations of weather. The slovenly farmer then laughs at the more perfect system of the other, pretending that it is wrong to work strong soils so much and make them *too fine*, as the term is. Thus the progress of a whole district in rational and improved culture is arrested or checked by the apparent evil of frequent ploughing. But the conclusion is founded in error. There can be no rule better confirmed by experience than that adhesive soils should be stirred and divided as much as possible; but this must be done with due regard to circumstances and seasons, and the differences in soils: chalking, marling, or manuring are necessary, in order to prevent the divided soil from *setting* into a hard, compact mass. Light-coloured clays which consist of siliceous sand and argillaceous earth only, without any intermixture of other substances, set the harder in drying the more they are stirred; after being ploughed they soon have the appearance of stripes of unburned brick; and if a heavy shower has fallen after the land has been harrowed, they become hard like a barn floor. It is of no use to pulverise such land, until its texture is altered by chalk, marl, dung, or ashes; and the safest way is not to stir it too much, as no good crop can be expected at all events till it be ameliorated. To prepare a middling stiff soil for beans, it should be ploughed into high and narrow lands in autumn, with numerous and deep water-furrows, so that no water may lie on any part of it, and, if possible, it should be manured with long dung before it is ploughed. In spring, if there has been some frost, the surface will be loose and mellow; in this the beans should be drilled or dibbled by hand, and a time should be chosen for hoeing them, when the ground is neither wet nor dry, so that the hoe, whether hand-hoe or horse-hoe, may penetrate two or three inches below the surface to open the soil and destroy the weeds. The hoeing of the beans is a most essential part of the culture, and according as it is well or ill executed the land will produce more or fewer crops after it without its being necessary to have recourse to a fallow. Objections have been made to the use of the horse-hoe and scarifier between the rows in stiff soils; because, when the ground is dry and caked, the hoe raises large clods and lays the roots bare, sometimes even destroying the plants. But there are means of preventing this: if the ground is repeatedly hoed when not quite dry, it will not bind into a hard crust or rise in clods; and should a sudden dry wind, after much rain, bake the surface in spite of every attention to it, a rough roller, of such dimensions as to work between the rows, will effectually loosen the soil, so that hoes and grubbers may follow without inconvenience.

When the beans have pushed their stems, and the proper leaves appear above the seed-leaves, the intervals should be carefully hoed, and, where it is practicable, three or four bushels of gypsum per acre may be sown, if the soil does not already contain this substance, and it will greatly stimulate the growth. The mode of its operation is not exactly known, but experience has proved its utility. [MANURE; GYPSUM.] A small quantity of gypsum seems to stimulate the growth of all leguminous plants and clovers; but if this quantity be already present in the soil, no additional quantity seems to have any effect. It has been recommended to cut off the tops of the plants when the lower pods are set, as is frequently done in garden culture, to accelerate the filling of them, and to prevent useless blossoms from drawing the nourishment to the top. The reason for doing this in gardens is, that when a plant has borne pods a certain time it is most advantageous to remove it, and the top blossoms, of course, never come to perfection. In the field this is not the case, there being no succession of plants; and, unless the top blossoms are very late, or the black dolphin (*aphis*) begins to appear, which is shown by the honey-dew on the top shoots, no advantage is gained by topping the plants, and the labour is thrown away. When the leaves of the beans begin to lose their green colour, and the pods to turn black, the crop should be reaped with the sickle and made into small sheaves, tied with straw bands or tar twine, and set up in the field to dry. In some places peas are sown mixed with the beans, or the headlands are sown with peas, the halm of which is used to tie the beans with; but peas cling round the bean-stalks and impede the setting of the pods; they also interfere with the hoeing and weeding, so that the practice is not to be recommended. Peas require a lighter soil, and are best sown separately, except when they are sown broad-cast mixed with beans, in order to be mown in a green state as fodder for cattle or for pigs. Sowing beans for this last-mentioned purpose is not much practised in England, but is found very useful on the Continent, especially in Flanders; in this case they are mown like tares soon after the pods are formed. In order to have a succession of this green food, they should be sown at different times, with a week or fortnight's interval. By this means a great deal of grass is saved, which may be reserved for hay; the cattle

fed in the stables or yards thrive well on this food, and produce a quantity of rich manure, chiefly in a liquid state, which fills the tanks and reservoirs which we have repeatedly mentioned as indispensable appendages to every good farm-yard. By having winter tares when the turnips are consumed, peas and beans after the first crop of clover, and summer tares to succeed them, cattle may be fed in the stables all the year round with great advantage, the land may be tilled at the best season of the year, and prepared for wheat, as well as by a clean fallow, while the green crop will fully repay all the expenses. Three bushels of beans and two of peas, mixed together, are required per acre when sown broad-cast, or drilled in each furrow after the plough. It is often advantageous to cut in a green state those beans which were sown for a general crop when food for pigs is scarce; they will go nearly as far in this way in feeding store pigs as the beans would have done when ripe, and the ground is left in a better state for the following crop.

Beans may be either sown by drill, in rows one foot to two feet apart, or hand-dibbled, or sown by hand or by barrow in the wake of the plough, under every second or third furrow-slice; or sown on manure in drills between ridgelets, 28 to 30 inches apart, being then covered by the splitting of these ridgelets, and the land being then partly harrowed down and rolled. The wider intervals are best when the bean is considered as a fallow crop. If the land be clean, an interval of 18 inches is sufficient to allow air and light for the proper setting of the blossoms and growth of the pods. When winter beans are sown, the stubble (wheat or oats) should be broad-shared and cleaned and ploughed. Manure may (20 cubic yards per acre) then be carted on the land, and spread and ploughed in; and the land, being harrowed, is ready for the drilling-machine. The seed, two or two and a half bushels per acre, may be sown in October, in rows about 20 or 24 inches apart, and the land, being harrowed down and water-furrowed, is left for the winter. The spring cultivation, horse-hoeing and hand-hoeing, is the same only earlier, as for any other sort. The crop is generally ripe a month before the spring-sown sorts, and therefore both less liable to blight, and better enabling a partial fallow before the seed-time of the wheat crop, which succeeds it. The winter bean is better for the lighter class of soils than other sorts. It is a heavy bean per bushel, and a good cropper.

Although beans grow best in a rather heavy soil, they are often profitable on much lighter land, especially after clover lea or grass, which is broken up after being depastured two or three years. This is an excellent preparatory crop for wheat, and better than oats, which leave such land full of weeds. In this case the land should be carefully ploughed up. For this purpose a skim-coulter, which has a small wing attached to it, to slice off the grassy surface of the land and turn it under the furrow, is a most useful appendage to the plough. This makes very clean work, and a heavy roller drawn across the ridges or lands leaves the whole surface compact and solid, keeping the moisture from evaporating and facilitating the slow decomposition of the roots of the grass. Thus a very good and clean crop of beans may be obtained. If the soil should be exhausted or very poor, a good coat of manure spread over the grass and ploughed in will be a great advantage to the beans and to the wheat which is to follow. On moderately light loams a profitable rotation of crops is that of turnips, barley, clover, beans, wheat; or, if it is in a rich state, turnips, barley, clover, oats, beans, wheat, beans. When land is in good heart, beans are often added to any rotation after wheat or before it, and the fallow is thus removed a year farther on. This is likewise done when it is intended to change the course of crops; because beans are considered the least exhausting of the crops which are allowed to ripen their seeds, and this practice is far less hurtful than the too common one of taking another crop of oats after the wheat, by which more harm is often done than the value of the crop can compensate for.

The diseases to which beans are subject are, the mildew, which is a minute fungus that grows on the stems and leaves, and is caused by cold fogs and frequent sudden variations of weather, and the black dolphin, an insect of the *aphis* tribe, which appears first in the form of a honey-dew on the tops of the plants. For the mildew, no remedy or preventive has yet been found: whenever it has attacked the plants generally, before the pods are filled, the best method is to cut down the crop in its green state, and if it cannot be consumed in the farm-yard, to plough it into the ground, where it will decay rapidly, and be an excellent manuring for the succeeding crop of wheat. If allowed to stand, the crop will not only be unproductive, but the weeds will infest the ground, and spoil the wheat crop by their seeds and roots, which will remain in the soil. Whenever the tops of the beans begin to be moist and clammy to the feel, it is the forerunner of the *aphis*. They should then be immediately cut off, and this, if done in time, may save the crop from the ravages of the insects; but the most effectual way to prevent any disease from attacking the plants in their growth is to have the ground in good heart, and well tilled; to drill the beans at a sufficient distance between the rows to allow of the use of the horse-hoe, and thus to accelerate the growth of the plants, and enable them to outgrow the effect of incipient disease, which seldom attacks any but weak plants.

The principal use of beans is to feed horses, for which purpose they are admirably adapted, and far more nourishing than oats. They should be bruised or split in a mill, and given to horses mixed with hay and straw cut into chaff; this will ensure proper mastication, and

prevent that thickening of the wind, as it is called, caused by indigestion, which makes beans alone not so well adapted for the food of hunters and race-horses. Great quantities of beans are consumed in fattening hogs, to which they are given whole at first, and afterwards ground into meal. Bacon hogs may be fattened entirely on beans and bean-meal; but as this food makes the flesh very firm, it is not so well adapted for delicate porkers. In the last period of their fattening, therefore, barley-meal is usually substituted for bean-meal. Bean-meal given to oxen soon makes them fat, and the meat is far better than when oil-cake is used for that purpose; mixed with water and given as a drink to cows, it greatly increases their milk. A small quantity of beans is generally mixed with new wheat when ground to flour; the millers pretend that soft wheat will not grind well without beans, and they generally contrive that there shall be no deficiency in the necessary proportion. Thus a quantity of beans is converted into what is considered as wheaten flour. This practice is well known to all bakers and dealers in flour; and as there are means of discovering the quantity of bean-meal in the flour, the ignorant and unsuspecting only are deceived, and the price of the flour to the skilful purchaser varies according to the quality. The bean contains a great deal of nutritious matter—23 per cent. of nitrogenous or flesh-forming substance and 48 per cent. of starch, with 10 per cent. of woody fibre, $3\frac{1}{2}$ per cent. of ash, and 14 or 15 per cent. of water, in its ordinary condition in the market. The ash of the grain and of the straw respectively contains, according to Way and Ogston ('Journal of the English Agricultural Society'), as follows:—

	Beans.	Straw.
Silica	0.88	3.86
Phosphoric acid	31.87	7.35
Sulphuric acid	4.50	3.21
Carbonic acid	1.94	22.73
Lime	8.65	21.29
Magnesia	6.55	4.88
Peroxide of iron	0.36	0.90
Potash	42.13	21.26
Soda	0.90	4.56
Chloride of Sodium	1.90	9.05
Chloride of Potassium	0.34	0.90
	100.02	99.99

These figures indicate a large demand upon the potash of the soil. The sulphuric acid and lime, present in considerable quantity, indicate also a considerable demand for gypsum, the compound of these two substances, which has in fact been found a good manure for the bean crop.

The French bean, kidney-bean, or haricot bean (*Phaseolus vulgaris*), is chiefly cultivated for its tender and succulent pod, being one of the most esteemed vegetables for the table. The varieties are innumerable, differing slightly in their qualities; they may be divided into two distinct kinds, the dwarf and the climbing; the former are the earlier, the latter the more productive. French beans are much less hardy than the common beans; a very slight degree of frost will destroy them entirely. The early sorts are therefore sown in sheltered situations, and occasionally protected by glass frames or mats. The climbing beans require the support of sticks or wires, round which they twine as they grow, with this peculiarity, that the coils turn round the support from the right to the left, contrary to the growth of some indigenous twisting plants, which turn from the left to the right, following the apparent diurnal motion of the sun.

The French bean, as an esculent vegetable, is wholesome and nutritious in a fresh state, and may be readily preserved for winter store or sea voyages by salting in casks. For this purpose the large, flat-podded, Dutch white runner is preferred. In Holland and Germany, where large quantities are salted in almost every family, a machine is used for cutting them expeditiously, which greatly resembles a turnip-slicer, and may, with a slight alteration, be used also for slicing cabbages when making the national German preparation of sour-kraut (*sauer-kraut*). It consists of a wheel or disc, A, in which two or four knives are set at a small angle with the plane of it, so as to shave off a thin slice obliquely from the beans, which are held in a box, C, with several partitions in which they are kept upright, so as to slide down in proportion as they are cut: thus six or eight beans are sliced at once, and very rapidly, merely by turning the handle B, and supplying the box with beans in succession. The sliced beans fall on the table below, and are immediately put in a cask with alternate layers of salt. When the cask is full and well pressed down, a round board is put over the beans and a heavy weight upon it. As the beans are compressed, and begin slightly to ferment, the liquor is poured off, some fresh salt is strewn over the surface, and a linen cloth is pressed close upon it to keep out the air; the round board and weight are put over the cloth, and so the beans remain till wanted for use. When any are taken out, they are washed in soft water to take out the salt, and gently stewed with a little gravy, or with milk and a piece of butter. They form a very wholesome vegetable dish at a time when fresh vegetables are scarce. The dried seeds are also boiled after being soaked in water for some time, and are usually mixed with the preserved green beans in the same dish. This use of the French bean is not common in England; but when we take into consideration that they are extremely

wholesome and nutritive, much more so than peas, and that they are an admirable corrective of the oily qualities of animal fat by their farinaceous qualities, we shall regret that both the culture and the use of them in the dry state are not extended for the benefit of the labouring part of the community. The cultivation of the French bean

[Bean Cutter.]

for the seed is confined in this country to the gardens and nurseries, and to a few spots in the Isle of Thanet in Kent, where they are raised for the London seedsmen. This is the only place, as far as our observation goes, where they are sown in the field. The produce in seed is said not to exceed twenty bushels per acre, but it must be observed that it is chiefly the dwarf sorts which are sown. There is no doubt that the produce of the runners would greatly exceed this quantity, and although it might be expensive to support them with sticks, the example of the hop grounds proves that, where the return is large, no expense or trouble is spared.

The best soil for French beans is a rich mellow loam, rather light than otherwise; but, provided the ground be well stirred, they will grow in any soil. They may be planted in rows, the dwarf sorts at two and a half or three feet distance; the runners, at four feet. As soon as the stems begin to rise above the seed leaves, the intervals should be well hoed with the horse-hoe, and the rows by hand. The scarifier or grubber may be used to loosen the soil, and when they are somewhat advanced in growth the runners may have sticks to climb upon. A row of turnips may be sown between every two rows of beans, or cabbages may be planted for cattle. The crop may be harvested as soon as the lower pods are quite dry and the seeds hard, and threshed like other beans. The seeds when raw have a bitter taste, and are rather tough under the teeth, which makes animals refuse to eat them in that state; but when boiled, they become soft and pleasant. Oxen and pigs eat them readily. They contain, according to Einhof, 84 per cent. of nutritive matter, of which 50 is pure farina, the rest gluten and mucilage: they are consequently superior to every other grain or pulse cultivated, in point of nourishment; and when it is taken into account that they remain in the ground only from May to September, and that a crop of cabbages or turnips is growing in the intervals at the same time, it will appear that the cultivation of this pulse on a large scale might add greatly to the resources of agriculture.

In the three years ending with 1858, the importation of foreign beans amounted on an average to 357,000 quarters annually.

BEAR, GREAT AND LITTLE. [URSA MAJOR AND MINOR.]

BEAR'S WHORTLE-BERRY, the generic and specific characters of which are given under the article ARCTOSTAPHYLOS UVA URSI [NAT. HIST.], was used in medicine by the ancients, fell into neglect, and was restored about the middle of the last century. It possesses manifest astringent and, under certain circumstances, diuretic properties. The leaves are the part of the plant which is used. These are destitute of

smell, but have an astringent, bitter taste. Analysed by Meissner, 100 parts contained

Gallie acid	1.20
Tannin, combined with gallic acid	36.40
Resin	4.40
Chlorophylle	6.35
Extractive, with malates and other salts	3.31
Ditto, with citrate of lime	0.86
Gum and extractive	33.30
Lignin	9.60
Water	6.00

101.42

The leaves are frequently intermixed with those of the *Vaccinium vitis Idæa*, or cow-berry, from which they may be distinguished by not being spotted nor having the margin revolute. The watery infusion of the cow-berry leaves, treated with muriate of iron, merely becomes green. The watery infusion of the bear-berry so treated throws down a blackish-gray precipitate; also with the leaves of the *Vaccinium uliginosum*, or bog whortle-berry. To distinguish them from these last is more important than from the foregoing, as the leaves of the bog whortle-berry are poisonous. They do not possess the leathery texture, or the reticulated character of the leaves of the *Uva ursi*. The leaves of the *Bucus sempervirens*, or common box, are often fraudulently intermixed with it. They may be distinguished by the veins of the leaves running from the mid-rib to the margin, not being reticulated like the *Uva ursi*, having an unpleasant smell, and yielding on analysis the principle called *bucuin*.

The power of the leaves is greatest over the mucous membranes and the kidneys. The leaves rubbed with cold water yield up all their tannin and gallic acid, and thus afford an infusion of great efficacy in hæmorrhages from the prostate gland. In cases of tendency to calculous diseases, especially of the phosphatic diathesis, it is of great use when persevered in; also in catarrh of the bladder. It has been thought useful in consumption, and indeed its tonic power may render it occasionally serviceable. It is administered in powder, in the form of an infusion or decoction; but the best form in which it can be longest used is that of extract, as recommended by Dr. Prout.

(See Prout, *On Diseases of the Urinary Organs*, second edit., p. 185.)

BEARD, the hair which grows upon the chin and contiguous parts of the face in men, and sometimes, though rarely, in women. With men its growth is the distinctive sign of manhood. In its anatomical character it is shorter and thicker than the hair of the head; but longer, if suffered to grow, than that of other parts of the body. It generally, but not invariably, is of the same colour as the hair of the head, but always the same as that of the eyebrows. It is most prolific among men of what are called the Caucasian race; many of the peoples of Africa, America, and Australia have little or no beards. Some animals are provided with beards, or, as they are called, whiskers, which are held to be organs of touch.

The fashion of the beard has varied greatly in different times and different countries; and some of the learned in curious trifles have spared no pains to record the changes. Hotoman wrote a treatise expressly on the beard, entitled 'Pogónias' (ΠΟΓΩΝΙΑΣ), first printed at Leyden in 1586, and which, on account of its rarity, was reprinted at length by Pitiscus in his 'Lexicon.'

The earliest notice of attention to its growth is probably in Leviticus, where the lawgiver of the Jews (chap. xix. 27) says, "thou shalt not mar the corners of thy beard."

Generally speaking, the growth of the beard was cultivated among the nations of the East, although it must be observed that most of the Egyptian figures in the ancient paintings are without beards. In Rosellini's work we have a series of portraits of Egyptian kings, nearly all without beards. (See Plate No. x. &c.) From some of the statues, however, a curious beard-case appears to have been worn. The Memnon's head in the British Museum has this appendage, though no hair is shown on any part of the face. Another small bust, of which we give a representation, illustrates its appearance. The ancient Indian philosophers called Gymnosophists were solicitous to have long beards, which were considered symbolical of wisdom. The Assyrians and Persians also prided themselves on the length of their beards; and St. Chrysostom informs us ('Opera,' edit. Montfauc. tom. xi. p. 378) that the kings of Persia had their beards interwoven or matted with gold thread. The figures on the Assyrian slabs, brought to England by Mr. Layard, are usually represented with beards; and generally the beards on the reliefs from Persepolis in the British Museum, are most elaborately executed in a series of minute curls. Something of the same style of beard is still preserved in Persia, where it is dressed and trimmed with extreme care.

Aaron Hill, in his 'Account of the Ottoman Empire,' folio, London, 1709, p. 45, draws this distinction between the Persians and the Turks:

"The Persians never shave the hair upon the upper lip, but cut and trim the beard upon their chin, according to the various forms their several fancies lead them to make choice of; whereas the Turks preserve with care a very long and spreading beard, esteeming the deficiency of that respected ornament a shameful mark of servile slavery." The slaves in the seraglio are shaved as a mark of servitude.

Athenæus (xiii. p. 565, edit. Casaub. Lugd. 1657) observes from Chrysippus's treatise 'De honesto et voluptate,' that the Greeks wore their beards till the time of Alexander. The first person who cut his beard at Athens, he adds, was ever after called *κόρην*, the shaven. Plutarch, in his 'Life of Theseus,' mentions incidentally that Alexander cut off the beards of the Macedonian soldiers, that they might not be used as handles by their enemies in battle. The Greeks continued to shave the beard till the time of Justinian, under whom long beards came again into fashion, and so continued till the taking of Constantinople by the Turks, in 1453. The Greek philosophers usually made the beard a distinguishing feature in their appearance, whence the proverb *ἐκ παργωνος σοφός*. Persius ('Sat.' iv. 1) terms Socrates *magister barbatus*, the "bearded master;" and Prudentius ('Apoth.' ii. 200) bestows the same title of *barbatus* upon Plato.

Varro ('De Re Rustica,' lib. ii. c. 11, edit. Commelin. 8vo, 1595, p. 126) and Pliny, following his authority ('Hist. Nat.' edit. Harduin, lib. vii. c. 59), say that the Romans did not begin to shave till the year of the city 454, when Publius Ticius Mena brought over barbers from Sicily. Scipio Africanus, Pliny adds, was the first Roman who shaved every day. The first day of shaving among the Romans was subsequently considered as the entrance upon the state of manhood, and was kept with festivities like a birth-day. This practice is alluded to by Juvenal ('Sat.' iii. 186). Alexander ab Alexandro ('Genial. Dier.' lib. v. § 18) says the Roman youth consecrated the first fruits of their beards to some god; a custom which is illustrated by passages in Martial, Statius, and other authors.

Augustus, and the Roman emperors his successors, till Hadrian, shaved, as appears by their coins. Hadrian was the first emperor who wore a beard. (See 'Dion. Cassius,' edit. 1750, lib. lxxviii. p. 1132.) Plutarch says he wore it to hide the scars in his face. The emperors who followed Hadrian continued to wear beards. (Pancirollus 'de Rebus Memorabilibus,' edit. Francof. 1660, p. 163.) Rasche, however, in his 'Lexicon Rei Num.' notices the circumstance of Augustus suffering his beard to grow as a mark of grief for the death of Julius Cæsar; and says that certain coins struck about this time at Aria, A.U.C. 710, present the portrait of Augustus bearded. Dion. Cassius, lib. xlviii. (edit. Hamb. 1750, tom. i. p. 551), says that Augustus put off his beard about A.U.C. 717, with great ceremony and feasting. Antoninus Pius and Marcus Aurelius wore lengthened beards as philosophers; though Aurelius, when young, is represented without a beard. Some of the Africans wore long beards, as may be seen upon the coins of Juba. (See Rasche, 'Lexicon Rei Num.' tome ii. p. 2, col. 1018.)

It would require no small space to enter minutely into the history and vicissitudes of the beard among the nations of modern Europe. The Lombards, or Longobardi, derived their name entirely from its length: and Eginhard, the secretary of Charlemagne, informs us that the Merovingian, or first race of French kings, were equally solicitous to nourish its growth; though at a later period among the French it should seem that the common people shaved the whole beard.

The ancient Britons, according to Cæsar ('De Bello Gall.' lib. v. c. 14), wore no beards except upon the upper lip. He probably spoke of the Kentish Britons only, or of the tribes who immediately adjoined them. Strabo speaks of the beards of the inhabitants of the Cassiterides, the Scilly islands, as in his time like those of goats. ('Geogr.' edit. Falconer, Oxf. 1807, fol. lib. i. p. 239.)

Tacitus, speaking of the Catti, one of the ancient German nations, says, from the age of manhood they encouraged the growth of the hair and beard, nor would lay them aside till they had slain an enemy. ('De Mor. Germanorum,' c. xxxi.)

The Anglo-Saxons, at their arrival in Britain, and for a considerable time after, wore beards. In the Anglo-Saxon MSS., St. Dunstan is represented with a beard and whiskers; and on the Great Seal, Edward the Confessor has a pointed beard and moustaches. (See Knight's 'Popular History of England,' vol. i. pp. 136 and 165, where they are copied.) The clergy, however, were very early obliged to shave their beards in obedience to the laws, and in imitation of the practice of all the Western Churches. This distinction between the clergy and the laity subsisted for some time; and a writer of the 7th century complains that the manners of the clergy were then so corrupted, that they could not be distinguished from the laity by their actions, but only by their want of beards. By degrees the English laity began to imitate the clergy so far as to shave all their beards except the upper lip.

The English spies who were sent by Harold to discover the strength and situation of the Duke of Normandy's forces, returned with the account that almost all his army had the appearance of priests, as they had the whole face with both lips shaven. (See Malmesbury, lib. iii.) The Normans, indeed, not only shaved their beards themselves, but when they became possessed of authority, they obliged others to imitate their example. It is mentioned by some of our historians as one of the most wanton acts of tyranny in William the Conqueror, that he compelled the English (who had been accustomed to let the

hair of their upper lip grow) to shave their whole beards; and this was so disagreeable to many of them, that they chose rather to abandon their country than to lose their whiskers. (See 'Mat. Paris,' edit. 1640; 'Vit. Abbat. S. Albani,' tom. i. p. 46.) Ordericus Vitalis, p. 815, relates a curious anecdote of Henry I. submitting to lose his beard at the remonstrance and by the hands of Serlo, archbishop of Sens.

In the higher classes of society the beard, in a greater or less degree, was encouraged by the English for a series of centuries, as is evident from the sepulchral monuments of our kings and chief nobility, and from portraits where they remain. Edward III. is represented upon his tomb at Westminster with a beard which would have graced a philosopher. Stowe, in his 'Annals,' edit. 1631, p. 571, in his account of the reign of Henry VIII. under 1535, says, "The 8th of May the king commanded all about his court to poll their heads, and, to give them example, he caused his own head to be polled, and from thenceforth his beard to be knotted, and no more shaven." The practice of wearing the beard continued to a late period; and the reader will readily call to recollection the portraits of Paulet Marquess of Winchester, Cardinal Pole, and Bishop Gardiner, all ornamented with flowing beards, in the reign of Mary I. In the reign of Elizabeth, beards of different cut were appropriated to different characters and professions. Shakspeare, in 'Henry V.,' act. iii. sc. 6, speaks of a "beard of the general's cut." Mr. Knight has remarked on the passage, that "beards of a particular cut had then appropriate names, and were sometimes characteristic of professions." The *steeletto* beard and the *spade* beard appears to have belonged to the military profession; though the cut of particular generals—settlers of the fashion—might vary. Southampton is always represented with the *steeletto* beard, Essex with the *spade* beard." The soldier had one fashion, the judge another, the bishop different from both. Malone has quoted an old ballad, inserted in a miscellany entitled 'Le Prince d'Amour,' 8vo, 1660, in which some of these forms are described and appropriated. (See Reed's 'Shaksp.' 8vo, Lond. 1803, vol. xii. p. 399.) Taylor, the Water-Poet, in his 'Whip of Pride,' likewise describes the fashions of the beard as they still continued to subsist in his time:

"Now a few lines to paper I will put,
Of men's beards' strange and variable cut;
In which there's some do take as vain a pride
As almost in all other things beside.
Some are reap'd most substantial like a brush,
Which makes a nat'ral wit known by the bush;
(And in my time of some men I have heard,
Whose wisdom have been only wealth and beard.)
Many of these the proverb well doth fit,
Which says, 'Bush natural, more hair than wit.'
Some seem as they were starch'd stiff and fine,
Like to the bristles of some angry swine;
And some (to set their love's desire on edge)
Are cut and pruned like to a quickset hedge.
Some like a spade, some like a fork, some square,
Some round, some mow'd like stubble, some stark bare;
Some sharp, stiletto-fashion, dagger-like,
That may with whisp'ring, a man's eyes outpike;
Some with the hammer-cut, or Roman T,
Their beards extravagant reform'd must be;
Some with the quadrate, some triangle fashion,
Some circular, some oval in translation;
Some perpendicular in longitude,
Some like a thicket for their crassitude.
That heights, depths, breadths, triforme, square, oval, round,
And rules geometrical in beards are found.

* * * * *
The barbers thus (like tailors) still must be
Acquainted with each cut's variety."

The beard now gradually declined, and the court of Charles I. was the last in which even a small one was cherished. After the restoration of King Charles II., moustachios or whiskers continued, but the rest of the face was shaven; and in a short time the process of shaving the entire face became universal.

The beard went out of fashion in France in the reign of Louis XIII., and in Spain when Philip V. ascended the throne. In Russia it continued somewhat longer. Butler, in his 'Hudibras' (part ii. canto i.), alludes to the beard "cut square by the Russian standard." Dr. Giles Fletcher, in his 'Treatise of Russia,' observes, "that the Russian nobility and quality accounting it a grace to be somewhat gross and burly, they therefore nourished and spread their beards to have them long and broad. This fashion continued among them till the time of the Czar Peter the Great, who compelled them to part with these ornaments, sometimes by laying a swingeing tax upon them, and at others by ordering those he found with beards to have them pulled up by the roots, or shaved with a blunt razor, which drew the skin after it, and by these means scarce a beard was left in the kingdom at his death: but such a veneration had this people for these ensigns of gravity, that many of them carefully preserved their beards in their cabinets, to be buried with them, imagining perhaps that they should make but an odd figure in the grave with their naked chins."

Within the last fifty years, however, the beard has made its re-appearance in most European countries, and with it the moustache and whiskers. Its first use would seem to have been in the French army during the rule of Bonaparte; from thence it extended to

civilians; then to Italy; then to Germany; then to Spain and Russia; and, lastly, to England, where, though yet far from general, it is evidently on the increase. Its retention has been advocated by some medical men as conducing to health; and while the British army was in the Crimea, directions were issued to allow the soldiers to wear their beards, which they are still allowed to, with certain restriction.

The reader who desires further information on the history of beards may consult the lexicons of Hoffmann and Pitiscus for the classic times; and in Bulwer's 'Anthropometamorphosis, or Artificial Changeling,' 4to, Lond. 1653, pp. 193-216, scene xii. is a whole chapter 'On the opinion and practice of diverse nations concerning the naturall ensigne of manhood appearing about the mouth;' quoted from innumerable authors, ancient and modern.

Shaving the beard in derision was, throughout the East, considered to be the greatest mark of ignominy which could be inflicted upon an enemy (2 Sam. x. 4, 5); and to pluck a man's beard was the highest mark of insult. The Eastern origin of some of our old romances is, perhaps, in no circumstance more visible than in the descriptions which are so frequently given of giants cutting off the beards of princes who fell into their hands. Drayton alludes to this practice in his 'Polyolbion,' Song iv.:

"And for a trophy brought the giant's coat away,
Made of the beards of kings."

Beards were considered to be of great use in enchantments. Spenser ('Faerie Queene,' book vi. canto i. v. 15) tells of the lady Briana, who to her suitor

"Refused had to yield her love againe,
Untill a mantell she for him do fynd,
With beards of knights and locks of ladies bynd."

The suffering of the beard to grow in the time of mourning is a custom which has been already incidentally alluded to. Levi, in his 'Succinct Account of the Rites and Ceremonies of the Jews at this present time,' 8vo, Lond., says, that for the seven following relations, namely, a father or mother, brother or sister, son or daughter, husband or wife, they must not shave their beards, nor cut their nails neither of their hands or feet, nor bathe for the term of thirty days; which term is called in Hebrew *Shyloshim*, which means thirty days.

To *beard*, in modern English, means to set at defiance, to oppose face to face in a hostile manner. Shakspeare, in 'Henry IV.,' act. iv. scene 4, makes Douglas say,

"No man so potent breathes upon the ground
But I will beard him."

BEARING, the direction of the line drawn from one point to another. It is a term usually applied to the points of the compass, as follows: If the line *BA* be in a N. W. direction from *B*, *A* is said to bear N. W. of *B*, or the bearing of *A* is N. W. To take bearings is to ascertain the points of the compass on which objects lie. The following example will serve to familiarise the word, by connecting it with a simple problem of trigonometry:

Cape B is twenty miles from Cape A, and bears S. E. of it. On board a ship *S*, Cape A is observed to bear N. N. E., and B bears E. by N.: required the position of the ship. Draw *SD*, *AC*, both east; then the angle *DSB* is one point of the compass, and the angle *DSA* six points: consequently, *ASB* is five points of the compass, or $56^{\circ} 15'$; but *CAS* and *ASD* are together equal to two right angles, or sixteen points, of which *ASD* is six points, therefore *CAS* is ten points; but *CAB* is four points, therefore *SAB* is six points, or $67^{\circ} 30'$; therefore, in the triangle *ABS*, the side *AB* and two angles are known, whence the other sides, or the ship's distance from the two capes, can be found. The easiest method of solving this problem is by actual construction, the results of which are generally as accurate as the data.

In a manner somewhat similar, the distance of a ship from a headland might be found by observing its bearings at two different hours of the day, and knowing the course and the distance sailed in the intermediate time. If all the bearings are by compass, as in the second problem, the magnetic variation need not be allowed for, because all the bearings are equally wrong; but if one or more be true bearings taken from a map, as in the first problem, then the bearings observed by the compass must be corrected. [AZIMUTH; COMPASS, AZIMUTH.]

The above diagram is a sufficient illustration of the purpose to which "bearings" apply at sea: it remains to describe the manner in which such are to be observed. Of late years considerable improvement has taken place in the mode of obtaining bearings at sea. The oscillation of the compass card was long an impediment to accuracy, and observations in azimuth could only be relied on to within a quarter of a point; but the improvements in compasses [COMPASSES], the increased size of merchant shipping, and the extended use of steam as a propeller, including increase of speed, have affected "navigation" to such an extent, that it will be a legitimate object in this Cyclopædia to condense within certain limits all that is known in nautical science up to the present,—all that is of public or general interest in that subject.

The operation of observing a bearing of a distant object has consisted in bringing the two sight vanes of an azimuth compass [COMPASS, AZIMUTH] in a line with the object, and then reading off the degree upon the compass card. If two objects were to be observed, the same operation was repeated with the second, and the difference in degrees or points of the compass gave the contained angle, and a good azimuth compass on shore would, on ordinary occasions, afford sufficient accuracy; but it is difficult at sea, even to a practised navigator, when a ship and the card have much motion, to catch the intersection of the object with the sight vanes at the very time of estimating or reading off the degree which then precisely faces the "lubber-line" of the instrument. And a highly experienced nautical surveyor has shown ('Nautical Mag.') that on frequent occasions the usual position of the azimuth or standard compass unfits it for convenient use. It is, indeed, placed so high above the deck on board iron ships or steamers, that an improvement in the method of taking a bearing was called for. Accordingly, Captain Becher, R.N., described a "dumb card," for general use; and a veteran and experienced officer, Lieut. Friend, F.R.S., invented and patented a species of dumb card, which he calls a "Pelorus." The navigator gains herefrom these great advantages; namely, his attention is not distracted by two observations, which ought to be simultaneous; but while he "sets" the distant objects by the sight-vanes of the Pelorus, his assistant, at a preconcerted signal, reads off the degree on the compass card. And again: it often happens that an island or headland is visible from aloft, but not so from the deck; in such cases, from the circumstance of the Pelorus, or dumb card, having no magnetic needle, it can be used with equal facility even in a ship's top-gallant cross-trees, if desirable, thus avoiding all considerations of attraction from contiguous chain-gear; and all that is necessary is for the observer to set the side of the square box of the instrument parallel to the fore-and-aft line of the ship, and at the moment of making the observation to raise a hand or the voice, when the man at the binnacle (by previous arrangement) records the bearing of the ship's head at the precise moment; and the bearing of the ship's head, compared with the angle which the object makes with the ship's head by Pelorus, will be the bearing of the object. For example: An object is seen to bear, by Pelorus or dumb card, 45° on the starboard bow, while the ship's head, by the binnacle, was N. by W. The difference between N. by W. and 45° , or four points eastward, will extend to N. E. by N. (the bearing of the object). The value of these instruments is increased by the introduction of another very recent discovery in astronomical science [SPHEROGRAPH]; and they are likely to be of immense importance in navigating foggy districts, inasmuch as a good bearing of the sun in a mist by day, or of a star or planet by night [HORIZON], obtained by a Pelorus, gives, in connection with the Spherograph, a good and reliable approximate latitude, &c., dispensing with the altitude. [DEAD RECKONING.]

Another recent change in the mode of taking bearings bids fair to prove extensively useful to navigators, and especially in iron ships or steamers. A well-known and experienced London merchant-captain, Charles Robertson, has invented and patented a "Deviation Detector." It is simply a brass arrow-shaped index, with a pin through its centre extending downwards and dropping into a hole in the centre of the covering-glass of a ship's compass. The pin is long enough to stand some three or four inches above the arrow, and by means of a joint in it admits of its being elevated or depressed vertically, as convenient. On the sun's true bearing being known by calculation (or by the spherograph), the arrow point is turned so that the shadow of the pin falls along the axis of the arrow, when the difference between the arrow point and the degree beneath it on the compass card marks at once the absolute error of the compass (including both deviation arising from terrestrial magnetism and the effects of local attraction).

For example: Suppose calculation, or "inspection," informs me that, at a given moment, the sun bears truly S.W. On turning the arrow point towards the sun, so that the shadow of the pin lies on the axial line, if the part of the compass card immediately under the arrow point reads S.W., the compass has no error, because then the true and magnetic bearings coincide; but if the card read S.S.W., and the true bearing (by the arrow point) read S.W., there will evidently be an error of two points of the compass. The importance of the instrument (simple as it is) may be inferred from the numerous and varied attempts which have long been made, to apply the principle in various forms in navigating an iron ship or steamer.

BEATIFICATION, an act by which the pope declares a "servus Dei," that is, an individual who died in good repute as a virtuous and holy man, to be beatified or blessed after death; that prayers may be

addressed to him, and his image be placed on the altar within the limits of some diocese, province, or town, or within the houses of the religious order to which the deceased belonged, defining at the same time the peculiar mode of worship allowed by prayers, masses, &c., until the time he may be duly canonised as a saint, to which beatification is a step. His relics may thenceforth be exposed, his image is crowned with rays, but neither are carried in procession; and though a special office is appointed in the Church service, the day of the office is not an obligatory festival, and it has no octave. The distinction between beatification and canonisation is this: The first is a mere permission to honour and worship, and the object of this veneration is styled *Beatus*, in which the pope does not act as a judge to decide on the condition of the person beatified; while in canonisation this is done, and an injunction is given to venerate the object of it as a saint, "*Sanctus*," acknowledged by the whole Church. Originally it was the bishop of the diocese who allowed the veneration or worship of deceased individuals whom he deemed worthy of it; and when the worship extended to other dioceses, and by degrees to the Church in general, "with the consent, tacit or expressed, of the supreme pontiff," then the worship, which was before that of simple beatification, acquired the character of canonisation. But when, in after times, the question both of beatification and canonisation was referred to the Roman see, the pontiffs, in granting the first, always made the distinction: "*dummodo propter præmissa canonizatus, aut canonizata, non censeatur*." (Benedicti XIV. '*Opera*,' vol. i. '*De Servorum Dei Beatificatione*.) In the same chapter Benedict XIV. determines the regulations as to the proceedings, evidence, &c., to be gone through previous to granting the writ of beatification. It may be granted to two classes of individuals, martyrs and confessors. After beatification has been obtained, a new suit and fresh evidence of sanctity are required in order to obtain the canonisation of the same individual. In May 1807, five *Beati* were canonised, or declared saints, in St. Peter's church, by Pius VII. The ceremony is very expensive, and therefore is not performed very frequently. It is only since the pontificate of Alexander VII. that the ceremony of beatification has been performed in St. Peter's church, with great solemnity; St. Francis de Sales, in Jan. 1662, being the first whose beatification was solemnised there. Applications for the honour of beatification are generally made by the friends or relations of the deceased, or by the brethren of the religious order of which he was a member; evidence of his conduct and merits is collected and laid before a congregation of cardinals and prelates; counsel is employed by the applicants, while another counsel opposes the petition, and endeavours to find flaws in the evidence. This latter office is performed by a legal officer of the Roman see, who has been nicknamed *l'Avvocato del Diavolo*, "the devil's advocate," as he performs what is considered an ungracious part, by opposing the admission of a candidate into the category of the saints.

BEATS, in Music (a term always used in the plural), are the pulsations, throbbings, or beatings, resulting from the joint vibrations of two sounds of the same strength and nearly of the same pitch; that is, of two sounds differing but little, if at all, in intensity, and which are almost, but not exactly, in unison. When two organ-pipes or two strings sounded together, are nearly, but not accurately, of the same pitch, that is, are not in perfect tune, they produce throbbings that may be compared to the rapid beating of the pulse; and to these *Sauveur*, the discoverer of the phenomenon, applied the term *battements*, or beats, which has since been adopted by all writers on the subject.

Mr. Woolhouse in his '*Essay on Musical Intervals, Harmonics, &c.*' London, 1835, says "Beats originate in the slight perturbation of the periodic coincidences of the vibrations which take place with the perfect chord, which perturbation makes one of them gain a little upon the other at these successive places of coincidence: and as soon as this small gain brings two consecutive vibrations about to another coincidence, a long cycle of the vibrations will be completed, and they will begin and perform a similar long cycle in the same manner, and so on. The coincidences at the beginning and end of these cycles are the times when the beats are heard, and consequently the time of the cycle is the same as that between two consecutive beats. They seem to be caused by the mutual concurrence of the vibrations in setting the particles of the surrounding air in motion, which makes the joint sound more loud at the places of coincidence, though not with sufficient frequency to produce the sensation of a continued sound."

Dr. Smith has, in his '*Harmonics*,' entered fully into the subject of *beats*, and founded hereon his well-known system of temperament. [TEMPERAMENT.] In his ninth proposition he says, that "if a consonance of two sounds be uniform without any beats or undulations, the times of the single vibrations of its sounds have a perfect ratio; but if it beats or undulates, the ratio of the vibration differs a little from a perfect ratio, more or less, according as the beats are quicker or slower." His experiment in demonstration of this is practical, easy, and satisfactory. "Change," says Dr. Smith, "the first string of a violoncello for another about as thick as the second. Then screw up the first string, and while it approaches gradually to a unison with the second, the two sounds will be heard to beat very quick at first, then slower and slower, till at last they make a uniform consonance without any beats or undulations. At this juncture, either of the strings struck alone, by the bow or finger, will excite large and regular

vibrations in the other, plainly visible; which show that the times of their single vibrations are equal." For the vibrating motion of a musical string puts other strings in motion, whose tension and quantity of matter dispose their vibrations to keep time with the pulses of air propagated from the string that is struck; a phenomenon explained by Galileo, who observes, that a heavy pendulum may be put in motion by the least breath of the mouth, provided the puffs be often repeated, and keep time exactly with the vibrations of the pendulum. "Alter the tension," continues Dr. Smith, in pursuing his experiment, "of either string a very little, and the sounds of the two will beat again. But now the motion of one string struck alone makes the other only start, exciting no regular vibrations in it; a plain proof that the vibrations of the strings are not isochronous." And while the sounds of both are drawn out with an even bow, not only an audible but a visible beating and irregularity is observable in the vibrations, though in the former case the vibrations were free and uniform. Now measure the length of either string between the nut and bridge, and when the strings are perfect unisons, mark, at the distance of one-third of that length from the nut, one string with a speck of ink. Then place the edge of the nail on the speck, or very near it, and press the string, when, on sounding the remaining two-thirds with the other string open, a uniform consonance of fifths will be heard, the single vibrations of which have the perfect ratio of 3 to 2. But on moving the nail a little downwards or upwards, that ratio will be increased or diminished; and in both cases the imperfect fifths will beat quicker or slower, accordingly as that perfect ratio is more or less altered.

Dr. Young remarks of *beats*, that they furnish a very accurate mode of determining the proportional frequency of vibrations, when the absolute frequency of one of them is known; or the absolute frequency of both, when their proportion is known; for the beats are usually slow enough to be reckoned, although the vibrations themselves can never be distinguished. Thus, if one sound consists of 100 vibrations in a second, and produces with another acuter sound a single beat in every second, it is obvious that the second sound must consist of 101 vibrations in a second. (Young's '*Philosophy*,' i. 390.)

In tuning unisons, as in the case of two or more pipes or strings, the operator is guided by beats. Till the unison is perfect, more or less of beating will be heard, as the sounds more or less approach each other. "When the unison is complete," observes Sir John Herschel, "no beats are heard: when very defective, the beats have the effect of a rattle of a very unpleasant kind. The complete absence of beats affords the best means of attaining by trial a perfect harmony. Beats will also be heard when other concords, as fifths, are imperfectly adjusted." (Herschel on *Sound*.)

Dr. Smith, in the learned work of which we have here availed ourselves, gives some useful practical rules for tuning by means of beats, the substance of which will be found under the head of TUNING.

BEAUTY is that quality in visible objects in consequence of which their colours and forms are agreeable to the human mind. The word *beauty* (as Mr. D. Stewart observes, '*Essay on Beauty*,' c. ii.) was first applied to objects perceptible by the sight; and, by an easy transition, it has been extended to objects perceptible by the hearing; as when we speak of beautiful music, a beautiful tune, voice, &c. The instances of words which properly signify an impression on one sense being used to signify an impression on another sense are very numerous: thus we sometimes pass from the sight to the touch, as when we speak of lightness or heaviness of form and of colour; from the touch to the hearing, as a sharp, piercing, thrilling, penetrating, or heavy sound; from the touch to the smell, as a pungent smell; from the touch to the sight, as harsh and soft colouring; from the hearing to the sight, as monotony of colour, tone of a picture, harmony of colours; from the taste to the sight, as mellow colouring; from the taste to the hearing, as sweet music.

This proneness to transfer words from one object of sense to another does not, however (as Mr. Stewart remarks), explain why the word *beauty* should be extended only to agreeable *sounds*, and not to agreeable *tastes* or *odours*. That, however, there is a closer affinity between the perceptions of sight and hearing than between those of sight and any other sense, it is not difficult to perceive; and the fact is satisfactorily traced by the same writer to the following causes:—1. The *picturesque* effect which custom, in many instances, gives to sounds; as when a tune calls up the image of a person's home or the haunts of his childhood. 2. The *expressive* power of sounds, as in the case of the human voice, when the expression of the countenance corresponds with the tones of the voice and the meaning of the words which it utters. 3. The significant power of sounds, in consequence of conventional speech. In this way they every moment present pictures to the imagination; and we apply to the description as to the thing described (with hardly any consciousness of speaking figuratively) such words as *lively*, *glowing*, *luminous*, *splendid*, *picturesque*. "To these considerations should be added (as the same writer justly observes), as a cause conspiring powerfully to the same end, the intimate association which, in our apprehensions, is formed between the eye and the ear, as the great inlets of our acquired knowledge, as the only *media* by which different minds can communicate together, and as the organs by which we receive from the material world the two classes of pleasures which, while they surpass all the rest in variety and in duration, are

the most completely removed from the grossness of animal indulgence, and the most nearly allied to the enjoyments of the intellect. The unconsciousness we have in both these senses of any local impression on our bodily frame may perhaps help to explain the peculiar facility with which their perceptions blend themselves with other pleasures of a rank still nobler and more refined." (Ibid. c. vi.)

But although the epithet *beautiful* is never applied to the perceptions of any sense except those of seeing and hearing, yet it is extended to the results of some intellectual processes, as when we speak of a beautiful chain of reasoning, a beautiful poem, a beautiful metaphor, a beautiful language, a beautiful machine, a beautiful contrivance of nature, &c. When the word *beauty* is thus employed, it is merely a vague term of praise, and is nearly synonymous with *admirable*. "The word beauty (as Mr. Knight remarks) is often applied to a syllogism or a problem; but then it means clearness, point, or precision or whatever else be the characteristic excellence of that to which it is applied." ('Inquiry into the Principles of Taste,' p. 259.) As the effect of beauty in visible objects is to produce admiration, all beautiful objects are also admirable; and thence it was an easy step to apply the epithet beautiful to things which produced admiration, although this feeling did not arise from the cause which produces it in the contemplation of visible objects. Similar transfers may be observed in other words: thus the word *law* properly signifies a general command given by one intelligent being to another; but because the effect of such a command is to produce an uniformity of conduct in the persons to whom it is addressed, the term *law* has been extended to those operations of nature in which an uniformity of phenomena prevails, although the cause of the uniformity is altogether different. [ANALOGY.]

In the following remarks on the nature and causes of beauty, we shall limit ourselves to the original and appropriate meaning of the word in question, namely, the beauty of *visible objects*.

The beauty of visible objects consists of two parts, namely, the beauty of colour and the beauty of form, which, although closely connected with each other, arise from different sources, and from sources of a different character, inasmuch as the one appears to be, in most cases, a simple emotion, and therefore an ultimate fact, of which no explanation can be given, while the other is a pleasure derived from association, which is susceptible of analysis.

There cannot, in our opinion, be any doubt that certain colours, and certain arrangements of colours, are naturally, and in themselves, pleasing to the eye. Children are observed to take delight in brilliant colours before they have learnt to connect any agreeable ideas with them. The analogy of the other senses would, *a priori*, lead to this conclusion: for as there are certain odours, tastes, and sounds, which are naturally pleasing or displeasing to the nose, the tongue, and the ear, so it may be presumed that there are certain colours, and combinations of colours, which are naturally pleasing or displeasing to the eye. Although, as will be presently shown, one branch of beauty is entirely founded on association, the feeling of beauty cannot be derived from association alone. "It is the province of association (as Mr. Stewart has justly observed) to impart to one thing the agreeable or disagreeable effect of another; but association can never account for the origin of a class of pleasures different in kind from all the others we know. If there was nothing originally and intrinsically pleasing or beautiful, the associating principle would have no materials on which it could operate." ('Essay,' i. c. 6.)

This origin of the feeling of beauty appears to us to consist in the pleasure derived from the contemplation of colours, a pleasure, in most cases, purely sensual and organic, and as incapable of explanation as the pleasure derived to the mind through the medium of the ear from the harmony of sweet sounds. An instance of purely sensual beauty is afforded by *precious stones*, which all ages and nations, ancient and modern, barbarous and uncivilised, have agreed in admiring. That their beauty does not arise from any collateral associations of their durability and hardness is evident from this, that in the unpolished state, when they are equally hard and durable, they excite no admiration. The precious *metals* also are beautiful for the same reason; though they have other qualities besides their beauty which give them exchangeable value: whereas the value of precious stones is almost exclusively owing to their beauty. Flowers, the plumage of birds, the rainbow, the setting sun, the clear blue expanse of the sky or the sea, also derive their beauty in great measure from the mere sensual impression on the organ of sight. Indeed, there are only a few cases (such as that of the beauty of complexion, which will be mentioned below), in which the beauty of colour is derived from association, and therefore admits of a resolution into simpler elements.

The beauty of form belongs altogether to a different category, and is derived (as we shall attempt to show) from an association inseparably connected with the form of any object, and necessarily and instantaneously suggested by it, namely, its adaptation to the purpose which it is intended to fulfil. The beauty of form, as arising from this source, is however subject to certain conditions, the chief of which is, that the object should either possess the beauty of colour, or at least should be of such a colour as is completely inoffensive to the eye. The beauty of form, although in strictness not connected with the colour of any object, is nevertheless so far dependent on it, that if the colour should be offensive to the eye, the pleasure derived from the beauty of form is much impaired, or is even destroyed. Beauty of form as

arising from the fitness of the form for its end, requires that the colour of the object should be such as shall not interfere with the effect produced by the mutual relations of its parts.

There is, however, another condition for the existence of beauty of form, beyond the perception of its fitness to its purpose, the statement of which will complete our definition of this kind of beauty. If, then, those colours are either absent or present, whose absence or presence is essential to the perception of beauty in any object, simply as an organic impression, the beauty of form in any object mainly depends on our sense of its adaptation to the end for which it is destined, provided that this end is *agreeable to contemplate*, and is such that the mind dwells on it with pleasure. Hence the form of the antelope, the swan, or the tiger, is considered beautiful, because we take a satisfaction in contemplating the movements which those forms are admirably fitted to produce; but the form of the pig's snout is not considered beautiful, because the mind flies with disgust from the filthy purposes for which that animal employs it. So likewise we call the outward form of the arms, legs, neck, &c., of the human figure beautiful, when their form is suited to their respective uses; but no one (except perhaps an anatomist) finds any beauty in the form of the human stomach, or intestines, or liver, though equally well fitted for their several ends, because they suggest the notion of processes which men do not willingly contemplate. (Burke's 'Sublime and Beautiful,' part iii. s. 6—8.)

Perhaps, in strictness, it might be thought that the simple emotion derived from the colour of objects is alone properly entitled to be considered as the feeling of beauty; and that the beauty of form in any object, derived from a sense of its fitness to its end, is only a pleasing association, allied indeed to the feeling of beauty by a close analogy, but still distinct from it. This question (which in fact is merely verbal) we have not sufficient space to discuss at length; nevertheless it appears to us that all ages and nations have agreed in speaking of the beauty of form as well as of colour, and that we are justified in considering as included in the feeling of beauty those emotions which are susceptible of analysis, as well as those which are not.

Having made these general remarks, we will proceed to explain, with somewhat more detail, the application of the principles last stated.

The beauty of form, arising from a perception of utility or of fitness of certain means to produce a certain end, may be observed both in animate and inanimate objects—in the works both of nature and of art. In animate beings we are gratified by the recognition that a certain form is suited to the wants of the animal, and that certain desired effects or motions are produced with ease and little effort. It is on this principle that we admire the beauty of the human form, every part of which is perfectly fitted for its intended purposes, and that we admire the motions of a horse, a stag, a greyhound, or a cat, as being made without any apparent trouble or difficulty, and as the result of a power which accomplishes its end with the least possible expense of exertion. The same feeling which makes us take pleasure in movements and forms which indicate ease, leads us likewise to dislike those which express constraint and toil; hence, both in nature and art, all forced and laboured attitudes, all tension of muscle, all visible and overstrained efforts to produce a certain effect, or to express a certain feeling (which is the source of affectation in art), are offensive to the taste. And thus all angular and jerking action, and all heavy dragging of the limbs, are devoid of beauty, as being signs of violent and toilsome effort, and as equally removed, though in contrary ways, from that equable, flowing, and easy motion in which grace consists. Nor is it only in animals that the marks of ease are agreeable to us; the varied, flowing, and irregular outline which characterises the free growth of plants, is beautiful on the same principle. It was the perception of this fact which induced Hogarth to imagine that beauty of outline consists in its serpentine direction, which is true of those animate and organised beings whose wants require them to assume this shape; but does not apply to other objects, such as buildings or walks, in which convenience requires a straight or angular form, and in which a straight or angular form is therefore beautiful. The beauty of proportion or symmetry in the forms of animals is likewise derived from a sense of utility; for it is manifest that small limbs would not suit the wants of a large body; that a large foot would be an incumbrance to a small leg; that a large hand would be an incumbrance to a small arm, &c. For the same reason different animals have different proportions, as their bodies are formed on different scales and adapted to different purposes; and thus the form or size which is beautiful in one animal would be monstrous in another, as if the long neck of the camelopard, an animal living on the leaves of trees, were given to the lion, whose teeth and claws are adapted to seizing and tearing the flesh of animals; or if the antlers of a stag were fixed on the forehead of a dog. (Horace, 'De Arte Poet.' at the beginning; on some exceptions to this principle, see Hogarth's 'Analysis of Beauty,' c. 6; Müller's 'Archæologie der Kunst,' § 24.) And thus the limbs of the human body, or the features of the human face, are beautiful only in their proper places, when they are taken in combination with the other parts of the body, and so manifestly suggest the notion that they are fitted to perform their respective offices.

"'Tis not a lip or cheek we beauty call,
But the joint force and full result of all.

All incongruous combinations in animate beings are contrary to beauty: for example, the pink and white complexion, which suits the delicacy and weakness of the female form and character, is less becoming to man, than the dark-red and brown, which characterise the sun-burnt cheek of a person accustomed to rural labours, to athletic exercises, to field-sports, and to a military or naval life. Somewhat feminine forms and colours are occasionally admired in very young men; and in women, as in the natives of the South of Europe, a dark complexion is often extremely beautiful: but an effeminate appearance is not more approved in men than an effeminate mind; and muscular or athletic forms in women are commonly considered coarse and clumsy, a judgment confirmed by the taste of the Greek artists, who, in representing Diana as a huntress, with her dogs, her arrows, and her garments girded up for running, never give her a masculine form; as, in their representations of Apollo, though they avoid muscularity, they carefully guard against the roundness and softness of limbs which are proper to female beauty. [APOLLO.]

Hence the *middle* form in the different species of animals is the most beautiful; that is to say, it is that abstract form at which the painter or sculptor arrives by rejecting all the faulty extremes, and which he takes as the type from which the varieties of individuals diverge in different directions. Thus the most beautiful size in man is between a giant and a dwarf; or, to take an instance in a single feature, the most beautiful form of the nose is when the outline is straight; any deviation from this form on either side, so as to make it like that of the fauns in Greek sculpture, or to give it a protuberance, is injurious to the beauty of the human countenance. (See Müller, 'Archæol. der Kunst,' § 329, n. 5.) And as it is with the general form of the human race, or of the several limbs and features, so is it with particular classes. Thus, "though the forms of childhood and age differ exceedingly, there is a common form in childhood and a common form in age, which is the more perfect as it is the more remote from all peculiarities." (Reynolds' Discourse 3.) Reynolds, however, is mistaken when he says that the middle form is beautiful because it is the most common (see 'Idler,' No. 82); for, as has been truly remarked, there are many forms of frequent and ordinary occurrence, which are by no means beautiful. The beauty of the middle form arises from its being that which is the most suited to the purposes and wants of the animal: thus, if a nose, a mouth, or an eye was very much above, or very much below the average size, it would either be inconvenient from its magnitude, or incapable of performing its functions on account of its smallness. Having once established this maxim in our minds, we forget, as in many other instances, the principle on which it is founded; and although a nose, for example, would be equally fitted for its purposes if it deviated slightly from the straight line, yet we consider that line alone as the standard of ideal beauty.

The reason why we are gratified by the perception of congruity or fitness in the general structure of an animate body and of its several component parts, by the appearance of ease and grace in the movements of animals, and universally by all the marks of activity, vigour, energy, and health, is that we are gratified by the absence of suffering, as we are pained by its presence; as when a person not hardened by custom to such sights witnesses an execution, a surgical operation, the slaughter of animals, a field of battle covered with the dead and dying, a hospital, &c. Hence all those objects which suggest the notion of pain, discomfort, or decay, are devoid of beauty. Such is the case with animals, as the elephant or the hippopotamus, which are heavy and cumbrous in their shape, and appear to drag their limbs with difficulty and effort; suggesting none of those impressions of joy and satisfaction in the animal, exulting in its strength and agility, which are occasioned by the unshackled movements of the horse, the antelope, or the stag. (See the comparison of the horse at the end of the 6th Iliad.) Hence, likewise, all deformity in animals is inconsistent with beauty, and is ugly in proportion as the shape of the limb or body deviates from the standard form, and is unfitted for the purposes for which it is intended.

For the same reason that deformity in animals is inconsistent with beauty, all appearance of disease, decay, and death is loathsome and hideous: as the ghastly look of a bleeding wound, the convulsive movements of agony, the pale, livid, or emaciated countenance of a person expiring under the rapid progress of a pestilential disease, or wasting away with famine, atrophy or consumption, the mouldering remains of a dead body, or the empty frame of a skeleton. Hence, when Romeo is described by Shakspeare as descending into the vault, in order to see Juliet's corpse, he says, on discovering that the bloom had not faded from her face,

"O my love! my wife!
Death, that hath suck'd the honey of thy breath,
Hath had no power yet upon thy beauty.
Thou art not conquered: beauty's ensign yet
Is crimson in thy lips, and in thy cheeks,
And death's pale flag is not advanced there."

The same feelings are transferred by us to the vegetable kingdom, though with a great diminution of their intensity: thus the yellow or brown colour of the faded leaf is for the most part less beautiful than the brilliant and vivid green of spring and summer vegetation; nevertheless, there is probably no person at all alive to the beauties of

external nature who has not admired the rich and varied tints of an autumn landscape, produced by the irregular discoloration of the leaf. When, however, decay has completed its work, all beauty vanishes; and a tree quite bared of its leaves has nothing more to recommend it to the eye than if it were actually dead. And when a tree has through age or by accident undergone a partial decay, its beauty is impaired, though its wreck may still suggest agreeable notions of power and grandeur, the memory of former vigour, of resistance to time and the elements, or to the destructive agents of nature. Such are in part the feelings excited by the sublime picture of Milton:—

"As when heaven's fire
Hath scathed the forest oaks or mountain pines,
With singed top their stately growth, though bare,
Stands on the blasted heath."

In general, however, all appearance of poverty, meagreness, or decline of vegetation is, unless compensated by countervailing circumstances, unfavourable to beauty. (See Price's 'Essay on Beauty,' p. 29.)

The beauty derived from a perception of utility is not confined to the works of nature, but is common to the works of constructive art, in which the adaptation of means to ends is equally observable, and in which there is a similar correspondence of the constituent parts. Thus in buildings each different part has a manifest and visible purpose—as the column to support a weight on the ground, the arch to support a weight over an opening, the windows to admit light and air, the projection of the roof to throw the rain-water from the walls, &c. Every part of a building has therefore its peculiar form and beauty, dependent on its destination. And the same is the case with different *kinds* of building: the disposition of parts which would be beautiful in a church or a palace, would be displeasing and absurd in a cottage or a fortified castle. "Grecian temples, Gothic abbeys, and feudal castles," says Mr. Payne Knight, "were all well adapted to their respective uses, circumstances, and situations: the distribution of the parts subservient to the purposes of the whole; and the ornaments and decorations suited to the character of the parts, and to the manners, habits, and employments of the persons who were to occupy them; but the house of an English nobleman of the 18th or 19th century is neither a Grecian temple, a Gothic abbey, nor a feudal castle; and if the style or distribution, or decoration of either be employed in it, such changes and modifications should be admitted as may adapt it to existing circumstances; otherwise the scale of its exactitude becomes that of its incongruity, and the deviation from principle proportioned to the fidelity of imitation." ('On Taste,' part ii. ch. 2. § 54; see also Lord Aberdeen on 'Grecian Architecture,' p. 26-35.)

For a similar reason, all ornament in architecture should be subordinate to use, and should grow out of and be suggested by it; whence professed architects, with whom the idea of decoration is predominant, often fail in their attempts to produce beauty, and in many cases seem rather to adapt the building to the ornaments than the ornaments to the building. Accordingly, it may be observed, that engineers whose attention is solely directed to the use of that which they plan, often construct more *beautiful* buildings than persons with whom beauty is the chief consideration. And generally, it may be observed, that all ornament, if accumulated to an excessive degree, either from a love of gaudy magnificence, or for the sake of ostentation, is devoid of beauty.

For the same reason that neatness, freshness, and regularity are pleasing to us in buildings, as being associated with the ideas of comfort and enjoyment, "we require," as Mr. Knight has observed, "that immediately adjoining the dwellings of opulence and luxury, everything should assume its character, and not only be, but appear to be, dressed and cultivated. In such situations, neat gravel walks, mown turf, and flowering plants and shrubs, trained and distributed by art, are perfectly in character" (ii. 2. 29). In laying out the direction of roads or walks, the beauty of the line is likewise determined by its fitness. Thus, in an open and level plain a straight line is most agreeable to the eye; in broken and irregular ground, the line which adapts itself to the shape of the country, by constantly keeping the same level, is to be preferred. The pleasure which is felt in following the windings of a road carried through a mountain-pass, and creeping round the declivities of the rocks, is enhanced by a sense of skill in the contriver and executor, and of difficulty successfully overcome.

The beauty of furniture and dress is likewise in a great measure derived from their *fitness*; though, with regard to dress in particular, our taste is liable to be determined by many independent, and often conflicting considerations, as novelty, fashion, &c., some of which will be mentioned below. Symmetry of parts, which the eye often so rigidly exacts in architecture, in gardening, in the internal decoration of a house, in dress, &c., arises in great measure from a sense of utility: thus, for example, in the construction of a house, the entrance is obviously best placed in the centre of the wall, as it affords the easiest communication to the various parts of the building; the windows are most convenient if they are at nearly equal distances from each other, and are not crowded together in some places and separated by wide intervals in others; the columns best perform their work if they are separated by equal spaces, and therefore support equal weights. The pleasure derived from symmetry in works of art is however not confined to its *beauty*, but in part arises from the evidence which it affords

of an uniform and extensive plan having been conceived and executed, and in part from that satisfaction which we take in the perception of resemblances, as well in outward objects as in the efforts of wit and imagination. It was probably the latter feeling (combined however with an excessive attempt to imitate in the garden the forms of architecture) which gave rise to the style of gardening described by Pope, in which

"Grove nods at grove, each alley has its brother,
And half the platform just reflects the other."—(*Epist.* 4.)

This formal style of gardening was founded on a just sentiment of what is suited to the immediate neighbourhood of a house, both in respect to the comfort of the inhabitants and the agreement with architectural forms; but in clipping shrubs into unnatural and fantastic shapes, and in laying out the ground in over-minute and complicated patterns, it sometimes carries a just principle to a vicious excess. (See Walpole's history of the modern taste in gardening, in his 'Anecdotes of Painting;' and Whately 'On Gardening,' § 139—47.)

The garden, in fact, forms the *transition* from the forms of architecture to those of landscape, and is a sort of middle term by which the hard, angular, and precise forms of art are melted into the flowing, irregular, and infinitely varied outlines of nature. Hence the quantity and character of the ornament in a garden ought to depend on the style of the building to which it belongs; and thus a richly decorated garden would not harmonise with a perfectly plain house; and, on the other hand, a large building loaded with architectural ornament seems to require something more than a few shrubs, planted irregularly around it, which scarcely differ in character from the neighbouring country. It is on this principle that small cottages and houses, which make no pretension to architectural beauty, are much improved by the growth of creepers and other plants upon their walls, which, as it were, makes them a part of the surrounding vegetation. On the other hand, in buildings which, from their imposing size and elaborate execution, have an independent character of their own, creepers usually suggest a notion of discomfort and neglect, a feeling which has no place if the building is not inhabited by man, and which, therefore, is not awakened by the sight of an ancient mouldering ruin overgrown with ivy. (See Price 'On the Picturesque,' vol. i. p. 287, vol. ii. pp. 134, 170, 177, 218; Lord Aberdeen 'On Grecian Architecture,' p. 45.)

The perception of fitness or congruity appears to us to account for the beauty of form in nearly all cases, and occasionally for the beauty of colour: there are, however, other circumstances which contribute to produce or heighten that feeling, or are conditions necessary to its existence. Such, for example, is the beauty of *expression* in the human countenance, when the notion conveyed to the mind is that of benevolence, cheerfulness, tranquillity, innocence, simplicity, or affection. (See Bacon's 'Essay on Beauty.') The distinctness and rapidity with which the eyes express the emotions of the mind contribute very powerfully to their beauty. *Novelty* likewise is, to a certain extent, essential to the perception of beauty; and as the most beautiful object would, by its continual presence, soon pall upon the sight, and produce complete indifference, so objects, whose beauty will not bear close examination, and is only calculated to please for a time, are agreeable merely from their novelty and freshness. This is the case to a great extent with fashions in dress, which are continually changing, and in which the newest fashion often seems the most beautiful, although it may have no other recommendation than its novelty. It does not, however, seem to us satisfactory to explain the beauty of modes of dress by saying, that "while they were in fashion they were the forms and colours which distinguished the rich and the noble, the eminent, the envied, the observed in society; they were the forms and the colours in which all that was beautiful, and admired, and exalted were habitually arrayed. They were associated, therefore, with ideas of opulence, and elegance, and gaiety, and all that is captivating and bewitching in manners, fortune, and situation, and derived the whole of their beauty from those associations." ('*Encycl. Britan.*' art. 'Beauty,' Suppl. vol. ii. p. 186.) For, in the first place, there is always a certain regard to utility in all kinds of dress and ornament for the person: colours are selected with reference to the colour of the complexion or hair, different dresses become the young and old, &c.; and those forms are usually chosen which, if not the most adapted to the motion of the limbs and the display of the natural beauties, are at least *consistent with them*. (See Hogarth's 'Analysis of Beauty,' c. 6, ad fin.) Caprice or bad taste may sometimes introduce such fashions as hair-powder, pomatum, and hoops, and habit may reconcile the eye to such monstrous disguises; but it seems incredible that any person should maintain that modes of dress are in themselves indifferent, and that the powdered and plastered hair and stiff hoop of an English or French lady of the 18th or middle of the 19th century are intrinsically as beautiful as the loose and flowing locks and graceful drapery of a Grecian statue. New modes of dress are worn, not because they are *beautiful*, but because they are *fashionable*. Ladies not unfrequently lament that the new fashion is ugly and unbecoming, though they abandon the old fashion as being obsolete. Brilliant colours, moreover, are almost universally considered beautiful for dress, especially for female dress; and therefore they are worn by the rich, who can afford a frequent succession of clothes: the poor, who cannot, are con-

sequently forced to clothe themselves in dark and dingy colours, which are not so soon soiled and spoilt. So likewise fine, soft, and smooth textures are not only more convenient, but more beautiful for clothing, as being better fitted to show the form of the body: in this respect the taste of all ages has agreed, from the Romans, who admired the cobweb garments, the *textilis aura*, which they imported from the East, and who bartered gold for an equal weight of silk, down to the modern purchasers of the delicate fabrics of Paisley and Lyons: and hence the rich clothe themselves in fine linen and woollen, in silk, in velvet, and in lace; while the poor, unable to purchase such luxuries, content themselves with coarser and thicker textures. In fact, however, the dress of the rich is not beautiful because it is the dress of the rich, but it is the dress of the rich because it is beautiful: costly furniture is not beautiful because it is costly, but it is costly because it is beautiful. The dress of the poor is not plain because it is the dress of the poor, but it is the dress of the poor because it is plain. In countries where the peasants ornament their dress with taste and fancy, as in some cantons of Switzerland, their dress is thought beautiful; in countries, as in ancient Venice, where the upper orders wore black clothes, black might have been considered a mark of nobility and rank, but could scarcely, even by the natives, have been considered as beautiful: nor in this country does any one think a barrister's or even a judge's wig and gown, a clergyman's surplice, or a bishop's sleeves, as having any title to be called beautiful because they are the dress of distinguished persons or professions.

Variety, likewise, is a condition of the beauty of colour nearly allied to novelty. Combinations of colours, if they are not so mixed as to be confused, and if their tints harmonise well together, are for the most part agreeable to the eye; while large and unbroken masses of an uniform hue, such as long flat walls, wide expanses of sand or water, or green plain, are devoid of beauty. The beauty of the human hair arises, in great measure, from the irregularity of its movements, its flexibility and variety of outline, and the changeability of its tint, as its glossy surface reflects the light in different parts; while a bald head is not only deprived of this ornament, but also seems to be shorn of its fair proportions, and to want something which belongs to its integrity.

The most remarkable exception to the ugliness of uniform colours, it has been said, is the beauty of the blue sky and the blue sea; but the colour is never uniform, in fact, but exquisitely graduated. Even, however, when the sea is most brilliant in its colour, how much do a few white sails, scudding along its surface, add not only to the interest but also to the beauty of the scene!

Some writers have thought that a certain *size* is an essential element of beauty: thus Aristotle, in his 'Poetic,' says, that beauty consists in *magnitude* and *proportion*; and, therefore, a very small or a very large animal would be devoid of beauty, the former because the eye could not *distinguish*, the latter because the eye could not *comprehend* its parts.* This notion of Aristotle's doubtless arose from his predominant love of making the excellence of everything to consist in a mean between two extremes; but in the case which he puts the mean is the beautiful form, because it is the best suited to the nature and wants of the animal. That beauty *generally* does not depend on the size of the object which makes the impression on the sense, is proved by the admiration which we equally bestow on the delicate frame and brilliant plumage of a humming-bird, and on the vast expanse of an Alpine view. Burke, on the other hand, makes *smallness* an essential element of beauty ('*Sublime and Beautiful*,' part iii. § 13); but the arguments which he adduces are equally untenable, as being founded on a partial view of the subject. Among other considerations he alleges the practice of giving diminutive names to the objects of our affection; but this arises not from any sense of the connection of beauty with smallness of size, but from the incompatibility of the passion of *love* with that of *fear*—that is, so far as fear means an anticipation of evil; for by using diminutive names, expressive of weakness and inferiority, men signify their consciousness that the persons whom they love are things in their power, of which they entertain no apprehension and do not stand in awe.

The feeling of beauty is, moreover, increased, if not awakened, by ancient recollections, which spread a charm over places illustrated by the arts, the learning, and the civil and military glories of former ages. It is, however, necessary to distinguish between the quality of *beauty* and the feelings excited by *interesting* historical associations. There is no doubt that the first time that a scholar beholds Athens or Rome, he is affected far more powerfully and agreeably than a person to whom ancient history is a blank. But these emotions cannot be considered as arising from the perception of beauty. It seems to us quite conceivable that a painter who did not know that Pericles or Socrates were Athenians, or that the Parthenon was the Temple of Minerva, should be as much alive to the *beauty* of the view of Athens as the historian, though his feelings would not be so strongly moved by the sight before his eyes. (See Knight 'On Taste,' part 2, ch. ii. § 70-73.)

* Το γὰρ καλὸν ἐν μεγέθει καὶ τάξει ἐστὶ, &c., 'Poet,' chap. vii.; and see Twining's translation, note 61, where several passages are cited showing the opinions of the Greeks as to the close connexion of large size and beauty. Our word *handsome*, in like manner, includes an idea of size above the ordinary standard.

This distinction between associations which give an *interest* to an object, which make us *curious* to see it, and those which make it *beautiful*, has not always been sufficiently attended to. Thus Mr. Alison cites Runnymede and the Rubicon as instances of beauty conferred or enhanced by historical associations. (Vol. i. pp. 25, 27.) But beauty never arises from such a source as this. No man would think a plain green field or an ordinary stream more beautiful than any other such field or stream, simply because King John had signed Magna Charta in the one, or Julius Cæsar raised the standard of rebellion on the banks of the other. A sincere Roman Catholic might be led into trains of the tenderest pathos and the loftiest religious enthusiasm by the sight of a fragment of the true cross, but would find no beauty in it. The iron crown of Charlemagne, or the stone on which the Scottish kings were crowned at Scone, would suggest historical recollections of deep interest, but would be devoid of beauty. The same may be said of badges of distinction, as orders, crowns, coronets, mitres, &c.; they may call up ideas of nobility, magnificence, grandeur, courage, or power, and yet they may not be beautiful. No one probably ever found any beauty in the Garter, the Victoria Cross, or the Cross of the Legion of Honour, however lofty or agreeable their associations may be. Feelings of this kind may make the mind susceptible to impressions of beauty, but cannot alone produce it. What can have less pretensions to beauty than a modern fortress, with its bare walls and heavy unornamented masonry? Yet it is inseparably connected with all those ideas of power, grandeur, martial prowess, and courage, to which Mr. Alison in other cases refers the origin of beauty.

Having thus attempted to give a general account of the origin and causes of beauty in outward objects, we shall next consider the *state of mind* which is most favourable to the perception of it.

In the first place it may be remarked that a *certain degree of cultivation* is necessary to the perception of beauty. Savage nations appear to be nearly or quite destitute of any notion of it, in the works both of nature and art, or at least their admiration, as in children, is confined to gaudy and shining trinkets and ornaments of the person. The practice of tattooing, however, is doubtless founded on notions of beauty, more mistaken even than those which led the ladies of Europe to cover their hair with powder and pomatum. In the lower orders of civilised nations the same indifference to beauty may be generally observed, in proportion to their coarseness and ignorance. The early development of the sense of beauty among the Greeks, which is so strikingly shown both in their mythology and poetry, and in their works of art (see 'Philological Museum,' vol. ii. p. 165-166), is a proof of their early culture and of their great superiority, even in a half savage state, to the barbarous nations by which they were surrounded.

Another thing essential to the perception of beauty is *sensibility of mind*, arising from the development of the social affections, and the cultivation of the benevolent feelings. The custom, prevalent in some countries, of planting flowers on graves, and of offering nosegays to the images of saints or of the Virgin, is a mark at once of a feeling of beauty and of sensibility of mind. On the other hand, persons of a sour, phlegmatic, morose, and misanthropic temperament, are little alive to the beauty of outward objects or works of art. It was, doubtless, from a sense of the incompatibility of a feeling for beauty with absence of all social and benevolent sympathies, that Milton represents the Devil as insensible to the beauties of Paradise:—

"The Fiend
Saw undelighted all delight, all kind
Of living creatures, new to sight and strange."

As on the one hand, all the antisocial passions, as anger, jealousy, envy, fear, &c., are inconsistent with the perception of beauty; so the social passions sharpen and facilitate it, as love and pity, which, as Dryden says, "melts the soul to love." Hence *loveliness* in the human race is intimately connected with beauty, as the desire of sex is heightened and stimulated by the beauty of form, colour, and expression; but it is not identical with it, for lovers are often not only blind to the defects of their mistresses, but sometimes even admire them on that very account: whence love is proverbially said to be blind.

A third requisite to the perception of beauty is *serenity and cheerfulness of mind*, and the absence of overpowering care or affliction, which engrosses the faculties and prevents them from taking pleasure in the relations of outward objects. This inconsistency is well illustrated by the reflections of Hamlet, when he is oppressed with a sense of the painful task imposed upon him by his father's spirit. (Act ii. sc. 2.) (See Alison 'On Taste,' vol. i. p. 10.)

On the relation of the beauty of outward objects to the beauty of works of art, more will be said under the heads of the several arts. Here it is only necessary to observe, that of the three arts of design, namely, architecture, sculpture, and painting, the two last are purely *representative* arts, while the first alone creates objects which have a *use* beyond the mere gratification of the taste. The beauty of buildings therefore belongs to the class of objects which we have been above examining; while the beauty of pictures and statues, though closely connected with the same range of ideas, yet forms a class apart, and requires the consideration of additional elements peculiar to itself. These are derived in great measure from the capabilities of the respective arts, as dependent on the materials which they work with and the effects which they are thus able to produce. There are many objects

beautiful in nature which cannot be represented with advantage by the painter or sculptor; on the other hand, there are many objects disagreeable in nature which are beautiful in a picture, because a picture is an abstraction, a representation of the colour and outline of an object, without any of those accompanying circumstances which in the reality may cause disgust to the other senses, and thus prevent the mind from enjoying that pleasure which it might otherwise derive through the organ of sight alone. Hence those things in nature which are peculiarly fitted to be subjects for a painter, are properly said to have *picturesque beauty*, as those forms and postures which would appear to most advantage in marble, might, as has been truly remarked, be said to have *sculpturesque beauty*. There are certain general characteristics of these two arts, as that painting best represents expression, whilst sculpture best represents character; that painting embraces a vast variety of subjects, whilst sculpture confines itself almost exclusively to the human figure and some of the nobler animals, which may be here pointed out; but to determine the peculiar provinces of these two arts respectively requires a separate investigation, with reference not to the general subject of beauty, but to the capabilities and advantages of each, and would be materially assisted by a knowledge of those mechanical processes and mysteries of art which the professed sculptor or painter can themselves alone possess.

(On the relation of the beautiful and the sublime, see the article *SUBLIMITY*; and on the more psychological view of Beauty of recent German philosophers, see *ÆSTHETICS*.)

BEBIRIC ACID. [BEBIRINE.]

BEBIRINE ($C_{33}H_{21}NO_6$). An alkaloid found by Dr. Rodie in the bark of a tree (the *Nectandra Rodiei*) growing in British Guiana, and used by the inhabitants as a remedy for fever, in the place of quinine. According to MacLagan, the Bebirine of Rodie contains two alkaloids; *bebirine*, possessing the above formula, and *sepirine*, which is a reddish-brown resinous body, that has not been further examined. Bebirine is a white, inodorous, amorphous powder, possessing a strong and persistent bitter taste. It is nearly insoluble in water, but soluble in alcohol and ether. It forms with acids bitter and uncrystallisable salts. Bebirine and sepirine are contained in the bark, in combination with *bebiric acid*, the composition of which is not known.

BEBIRINE, Medical uses of. The part used in medicine is the bark. It is derived from the trunk, and comes over in flat heavy pieces from 1 to 2 feet long, from 2 to 6 inches broad, and about 3 or 4 inches thick. The epidermis is brittle, and of a grayish-brown colour. Internally the bark is of a cinnamon-brown colour. The fracture is rough and fibrous. The taste is bitter, astringent, and aromatic. The seeds also contain the bebirine, on which the medicinal properties of the plant depends. The following is Dr. MacLagan's analysis of the two:

	Bark.	Seed.
Bebirine	2.56	2.20
Tannin and resinous matter	2.53	4.04
Soluble matter	4.34	9.40
Starch		53.51
Fibre and albumen	62.92	11.24
Ashes	7.13	0.31
Water	14.07	18.13
Loss	6.45	1.17
	100.00	100.00

The alkaloid bebirine is obtained by decomposing commercial sulphate of bebirine by ammonia; the precipitate is washed with cold water, triturated whilst still moist with moist hydrated oxide of lead, dried in a water-bath and exhausted rectified spirit; an alcoholic solution of bebirine is thus obtained. The alcohol may then be distilled from the bebirine. If this is heated with ether a part will be left undissolved. Dr. MacLagan thought this another alkaloid, and called it *sepirine*, but he now regards it as bebirine in an oxidised condition.

When bebirine is obtained from its ethereal solution, it is a yellow, amorphous, resinous-looking substance, but in the form of powder it is white.

The effect of the Bibiru bark is the same as that of cinchona. It is bitter and tonic, and possesses antiperiodic or febrifugal virtues. The alkaloid possesses the same properties; and from experiments which have hitherto been made, although it is not so powerfully febrifugal as quinine, it does not produce the headache, feverishness, singing in the ears, and other symptoms which are sometimes found to follow the administration of quinine. In intermittent and remittent fevers, in neuralgia, and as a genuine tonic it has been recommended, and especially in those cases where quinine disagrees.

BED OF JUSTICE. This expression (*lit de justice*) literally denoted the seat or throne upon which the king of France was accustomed to sit when personally present in parliaments. Under the ancient monarchy of France, a bed of justice denoted a solemn session of the king in the parliament, for the purpose of registering or promulgating edicts or ordinances. According to the principle of the old French constitution, the authority of the parliament, being derived entirely from the crown, ceased when the king was present; and consequently, all ordinances enrolled at a bed of justice were acts of the royal will, and of more authenticity and effect than decisions of parliament. The last bed of justice was assembled by Louis XVI. at Versailles, on the

20th of September, 1787, at the commencement of the French revolution, and was intended to enforce upon the parliament of Paris the adoption of the obnoxious taxes, which had been previously proposed by Calonne at the Assembly of Notables. But when the Duke of Orleans inquired of the king whether it was to be considered a *lit de justice* or a deliberative consultation, the king replied that it was a royal sitting. ('Thiers,' vol. i.) The edicts, however, were recorded, though there was much opposition.

BEDCHAMBER, LORDS OF THE, are officers of the royal household, under the groom of the stole. The number of lords is twelve, who wait a week each in turn; queens regnant are attended by a like number of ladies of the bedchamber, under a mistress of the robes. The groom of the stole does not take his turn of duty, but attends on all state occasions. There are thirteen grooms of the bedchamber who wait likewise in turn. All the appointments are in the royal nomination, and salaries are provided for all of them.

The title of lords of the bedchamber appears to have been adopted after the accession of the House of Hanover. They are first mentioned by that title in Chamberlayne's 'State of England,' for 1718.

BEDE-HOUSE, a term used for an alms-house. Hence *bede-man*, or *beid-man*, a person who resides in a *bede-house*, or is supported from the funds appropriated for this purpose. In the Court of Exchequer in Scotland, this term is used to denote that class of paupers who enjoy the royal bounty.

BEDESMAN, or **BEEDMAN**, from *bede*, a prayer, and that from the Anglo-Saxon *bid-an*, to pray, was a common mode of signature in the time of Henry VIII. at the end of letters; as of a prayer-man, or one who prayed for another. Sir Thomas More, in writing to Cardinal Wolsey, ordinarily styles himself "Your humble orator and most bounden beedman, Thomas More." (See Ellis's 'Orig. Letters illustr. of English Hist.' first ser. vol. i.) Margaret Bryan, the governess of the Lady Elizabeth, writing to Lord Cromwell, signs herself in the same manner, "Your dayly *bede-woman*." (*Ibid.* second ser. vol. ii.)

"Great men of old," says Mr. Knight in his 'Pictorial Shakspeare' illustrations of 'Two Gentlemen of Verona,' "did not wholly depend upon the efficacy of the prayers for their welfare which proceeded from the expectation or gratitude of their suitors. They had regularly appointed bedesmen, who were paid to weary Heaven with their supplications. It is to this practice that Shakspeare alludes, in the speech of Scroop to Richard II.:

"Thy very bedesmen learn to bend their bows
Of double fatal yew against thy state."

Colleges of bedesmen were also founded; and in Scotland the institution, in a modified way, continued, till a comparatively recent period. Scott's Edie Ochiltree, in 'The Antiquary,' was one of the king's bedesmen, who were expected "to pray for the royal welfare and that of the state."

BEDLAM, a corruption of Bethlehem, the name of a religious house in London, which, subsequently to the dissolution of monasteries, was converted into an hospital for lunatics, but still retained its former appellation. It was granted by Henry VIII. in 1547, with all its revenues, to the mayor, commonalty, and citizens of London, from which time only it became an hospital for the care of lunatics. In the infant state of this charity no other provision was made for the unfortunate patients, besides confinement and medical relief; it was left for the judicious benevolence of succeeding times to improve the good work, and to supply the subsistence and care which has restored so many distracted objects to their families and to society. There is no account of donations received for this institution before the year 1632. A New Hospital of Bethlehem, as it was then termed, was begun to be built in April, 1675, upon a plot of ground near London Wall; and this has since given way to a fitter building for its purpose, erected in 1814, upon a distant, but more commodious spot, but since greatly enlarged and improved. The Hospital of St. Mary Bethlem now stands upon the other side of the Thames, in the parish of Lambeth. [LUNATIC ASYLUM.]

BEDLAM BEGGARS was the ancient name for such patients of the Hospital of Bethlehem, after it became a lunatic asylum, as, being partially cured, were allowed to go at large; and also for impostors who personated the character. Edgar, in 'King Lear,' act ii. scene iii., when assuming the character of Poor Tom, says—

"The country gives me proof and precedent
Of *bedlam beggars*, who, with roaring voices,
Strike in their numb'd and mortified bare arms
Pins, wooden pricks, nails, sprigs of rosemary," &c.

Aubrey, in his 'Remains of Gentilisme,' an unpublished work, preserved among the Lansdown manuscripts in the British Museum, part iii. fol. 234 b., tells us, "Till the breaking out of the civil wars, Tom o' Bedlams did travel about the country. They had been poor distracted men, that had been put into Bedlam, where, recovering some soberness, they were licentiated to go a-begging; *i. e.*, they had on their left arm an armilla, an iron ring for the arm, about four inches long, as printed in some works. They could not get it off; they wore about their necks a great horn of an ox in a string or bawdry (baldrick), which, when they came to a house, they did wind, and they did put the drink given to them into the horn, wherein they put a stopple.

Since the wars, I do not remember to have seen any one of them." The ox-horn for holding their drink explains Edgar's speech ('Lear,' act iii. sc. 6), "Poor Tom, thy horn is dry."

BEDSTEAD. Bedsteads for domestic use, of whatever form, are most commonly made of wood, and of somewhat massive construction; but the much smaller space occupied by light bedsteads of iron and brass, their consequent superiority in favouring that free ventilation which is so important to health, and the great advantage which they possess in not harbouring vermin, have led to their extensive introduction of late years in the dormitories of barracks, hospitals, and other public establishments; while their elegant lightness, and the facility with which they may be taken to pieces, packed in a small compass, and put together in a short time, recommend them strongly for camp and travelling use, as well as, in many cases, for articles of household furniture.

Another class of bedsteads which claims notice, comprises those ingenious contrivances which have been devised for the comfort of invalids, and to facilitate the necessary surgical operations upon patients with fractured limbs, or such as have wounds requiring frequent dressing and careful shielding from the injuries incidental to even the most careful removal of the body. By means of such inventions—several of which, having been proved by experience to be efficient, have been rewarded by the Society of Arts—the position of a bed-ridden patient may be varied in many ways, with little or no exertion to himself, and the offices of the attendant and the surgeon may be performed with the greatest possible facility. Even these, however, have failed in one important point; for however perfect their mechanical arrangements may be, they cannot prevent the distressing consequences which arise from the unequal pressure of a body reduced to a state of extreme debility upon a bed which, however soft, cannot supply a uniform support to every portion of its surface. In many cases where the primary disease or injury has been insufficient to destroy life, mortification and death have ensued from this unequal pressure, notwithstanding the utmost care and the use of air-cushions and down-pillows to mitigate the evil. A painful case of this character having come under the notice of Dr. Arnott, led him to the invention of the *hydrostatic* or *water-bed*. This consists of a trough lined with thin sheets of metal, and partially filled with water, upon the surface of which floats a sheet of waterproof India-rubber cloth, of sufficient size to completely line the trough when empty, and secured to its upper edge in such a way as to prevent the escape of the water by capillary action. Upon this sheet is laid an ordinary soft feather-bed or mattress, which, floating on the yielding surface of the water, affords a support to the patient comparable only to that afforded by the water of a bath. Every point of the uneven surface of the body having, as it were, its separate column of support, the pressure is so equally distributed as to afford the patient comfortable rest, and effectually to prevent the formation of sores upon the most prominent points. The depth to which the body will sink in such a bed may be regulated by the thickness and buoyancy of the mattress; and any unusual position may be obtained by placing light and bulky cushions or folded blankets under such parts of the body as it may be desired to elevate, just as the position of a body floating in water may be affected by the use of buoys. The mass of water prevents the approach of cold air from beneath, and also, by its non-conducting properties, does not allow of the dispersion of heat downwards, so that, contrary to what might, at first sight, be expected, the hydrostatic bed is a warm one; but as the impermeability of the India-rubber cloth impedes the escape of perspiration, care should be taken, when the patient is unable to leave the bed daily, either to lay a waterproof cloth above the mattress to receive the moisture which would, without it, descend through the mattress, and becoming condensed on the floating sheet below it, would render the bed damp and unwholesome; to lay a blanket, which should be frequently changed, to collect the perspiration which descends from the bed; or to place a layer of small pieces of cork, the interstices of which may afford a degree of ventilation between the mattress and the floating sheet. The perfect adaptability of the surface of such a bed to whatever may be laid upon it, allows the dressing of wounds, the application of poultices, and the performance of other offices of the sick chamber, without disturbing the patient. This, like many other admirable contrivances, Dr. Arnott presented freely for the use of the public without retaining any patent right for himself.

Dr. Ridge's invalid bedstead is an ingenious contrivance, by which a person may be removed from bed with singular ease. There are, in fact, two beds one upon another, the uppermost of which can be lifted and removed by turning a handle. This upper bed, which is little more than a ticking stretched over an iron frame-work, is hinged in three parts, so that it may be made to assume any required position, from that of a horizontal bed to that of an easy-chair; so that it may be said the invalid may be taken from his bed without ever leaving it.

The Great Exhibition of 1851 presented, among others, two bedsteads which were types of two distinct classes. One was the Austrian bedstead, admirable for the extreme beauty of its carving. The other was the "state bed" by Messrs. Faudel and Phillips, one of the most elaborate specimens of modern needle-work; thirty needle-women were employed ten months in embroidering it; and the wool and silk threads employed were dyed in seven hundred different tints.

Mr. Hancock's *bed-chair* is another variety of bedstead. It consists of an air-tight India-rubber bag, so formed as to constitute a convenient bed or cushion when laid down horizontally and inflated with air; while it may be made into a sofa-chair or reclining-bed, by inflating one half of it through a separate aperture, and raising that half to any desired angle by means of suspending bands.

Another novelty, registered by Mr. Perkes in 1850, is a light iron frame-work, capable of being quickly made to assume any one of the four forms of a bed, a couch, a settee, or a crib. Like many similar contrivances, there is a light but strong cast-iron frame, the hinges and other parts of which admit of many different modes of adjustment. [AIR-CUSHION.]

BEECH; ECONOMICAL USES. The common beech, known in America as the *white beech*, is the most useful species of this valuable tree. The timber is hard, and is employed for a great variety of purposes. It is used for the keels and side-planking of ships; for ringing mill-wheels; for making piles, weirs, sluices, flood-gates, and other constructions exposed to the action of water; for cogs of wooden wheels; for making bedsteads and chairs; for panels of carriages; for various articles in joinery, cabinet-making, and turnery; for numberless small articles of household furniture; for railway-sleepers; for barn-floors; for herring-barrels; for wooden shovels and peels; for wooden screws and sieves. In Germany beech-wood is used for many of the purposes above named, and also for gun-carriages, wheel-felloes, bowls, porringers, salt-boxes, spindles, rollers, spinning-wheels, pestles, presses, bellows, and numerous other articles; while, sawn into thin boards, it is used for boxes, packing-cases, sword-scabbards, and even the boards of books (instead of millboard). In France, besides other purposes, beech is used for gun-stocks, plough-socks, cricket-bats, cheap knife-handles, and cheap *sabots*, or wooden shoes.

Beech is used to an enormous extent in France and Germany for fuel. The bark is used in tanning. The dried leaves are said to form an excellent substitute for feathers in beds, and to be largely employed in such a way in some districts. The dried catkins of the leaves are used to stuff cushions. The mast, or fruit, is eaten by many animals; and from this fruit an oil useful for lamps and for cooking is obtained. A *Beech-Oil Company* was one of the most noted commercial speculations of Queen's Anne's reign, at a time when joint-stock undertakings were but ill understood.

BEEF-EATER, a jocular appellation, as it is now used, for the yeomen of the guard; though it seems probable that the name of *buffetiers* was formerly assigned to that portion of the yeomen of the guard who from time to time waited at table at great solemnities, and were ranged near the buffets. (See 'Antiq. Repert.' edit. 1808, vol. ii. p. 398.) As yeomen of the guard, they were constituted by Henry VII., and they have continued as a royal institution to the present day, and with nearly the same costume as when first established, although in 1858 some modification was introduced into the ordinary habits of those who are stationed at the Tower; but the old costume is still worn on occasions of ceremony.

BEELZEBUB. [BAAL.]

BEER. The distinctions between different kinds of malt liquors are partially noticed under **ALE**, and will be found further elucidated under **BREWING**.

BEER-MACHINE, or BEER-ENGINE. In the ordinary beer-machine, each handle has a single action—that is, draws from one cask only; but in many respects it would be useful if two pumps could be worked at once by the same handle. From the rapid fluctuations which malt liquor undergoes in quality, owing to changes in the weather, it is frequently necessary for the retailer to mix old and new beer together, in order to maintain a uniform quality. This is done either by drawing from two butts, by two pumps and two handles, or by mixing beer of two ages in the same butt, by which a liability to a new fermentation is incurred. To obviate these inconveniences was the purpose of Ernest's beer-engines, patented a few years ago. The arrangement of this machine is very ingenious. One handle works the levers, rods, and pistons of two pumps, which may be connected with the beer in two butts. In the usual perpendicular position of the handle it works both pumps at once; but if drawn a little on one side, by a slight movement of the hand, it works one pump only—either one of the two, at pleasure. It is optional with the drawer whether to work one or the other pump, or both, and whether to draw equally or unequally from both.

BEES'-WAX. This important substance constitutes a secretion which is expelled through the interstices of the ventral plates of the honey-bee, and is employed by that insect in the construction of its cells. Bees'-wax is obtained from the expressed honeycomb by agitating the latter with boiling water so as to dissolve out the last portions of honey and other impurities. After allowing the mixture to stand at rest, the wax forms a layer on the surface, whence, on cooling, it may be removed as a solid cake. It is once more fused alone, and being then cast in moulds, forms *yellow* or *virgin wax*. *White*, or *bleached wax*, is obtained from the foregoing, by reducing it to thin strips and exposing the latter to the sun's rays for several days. It may also be bleached, according to Solly, by melting and agitating it with a small quantity of sulphuric acid, diluted with two parts of water to which some fragments of nitrate of soda are added. The bleaching process

ARTS AND SCI. DIV. VOL. II.

does not alter the chief constituents of the wax; the colouring matter only appears to be oxidised and bleached.

Bees'-wax fuses at 145° Fahr.; it is completely insoluble in water, but easily soluble in essential and fat oils. We are indebted chiefly to Professor Brodie for an insight into the chemical constituents of bees'-wax. It is composed of two principal bodies, formerly termed *cerine* and *myricine*. The first is soluble in alcohol, and has been proved by Brodie to be a peculiar acid, the *cerotic acid* ($C_{54}H_{92}O_2$, HO), homologous with acetic acid, crystallising in small grains and fusing at 172° Fahr. It is white, brittle, and volatile at a high temperature, and constitutes 22 per cent. of Surrey wax. According to the same chemist, myricine is an ethereal salt, consisting of palmitic acid united with the oxide of an organic radical, *myricyl* ($C_{60}H_{101}$). The formula of *palmitate of myricyl* (myricine) is $C_{32}H_{51}O_2$, $C_{60}H_{101}O$. Palmitate of myricyl is insoluble in boiling alcohol, fusible at 161°, and possesses a slight odour of wax. Treated with alcoholic solution of potash, it gives palmitate of potash, and *myricylic alcohol* ($C_{60}H_{101}O$, HO). [ALCOHOLS.] By destructive distillation palmitate of myricyl gives an homologue of olefiant gas,—*melene* ($C_{60}H_{60}$).

Bees'-wax is used in the manufacture of candles, and for modelling objects of art. It is also employed in the construction of anatomical models.

BEET, a plant of the genus *Beta*, in the natural order *Chenopodeæ*.

There are two distinct species of beet commonly cultivated, each containing several varieties, the one producing succulent leaves only, the other the *Vulgaris*, distinguished by its large fleshy root. The former is chiefly cultivated in gardens as a culinary vegetable, and forms one of the principal vegetables used by agricultural labourers and small occupiers of land in many parts of Germany, France, and Switzerland. A variety known by the name of Swiss *chard* produces numerous large succulent leaves, which have a very solid rib running along the middle. The leafy part being stripped off and boiled, is used as a substitute for greens and spinach, and the rib and stalk are dressed like asparagus or scorzonera; they have a pleasant sweet taste, and are more wholesome than the cabbage tribe. In a good soil the produce is very abundant, and if cultivated on a large scale in the field, this species of beet would prove a valuable addition to the plants raised for cattle. By cultivating it in rows, and frequently hoeing and stirring the intervals, it would be an excellent substitute for a fallow on good light loams.

All cattle are very fond of the leaves of this beet, which add much to the milk of cows without giving it that bad taste which is unavoidable when they are fed with turnips or cabbages, and which is chiefly owing to the greater rapidity with which the latter undergo the putrefactive fermentation. If sown in May in drills two feet wide, and thinned out to the distance of a foot from plant to plant in the rows, they will produce an abundance of leaves, which may be gathered in August and September, and will grow again rapidly, provided a bunch of the centre leaves be left on each plant. They do not sensibly exhaust the soil. These leaves, when boiled or steamed with bran, cut chaff, or refuse grain, are an excellent food for pigs, or bullocks put up to fatten.

The second species, the *Vulgaris*, or beet-root, has been long cultivated in gardens; especially that variety called the red beet, which, when boiled and sliced, makes such an excellent addition to winter salad. It is a native of the south of Europe, and hence all the varieties are tender, and destroyed by frost when in their young state. It thrives best in a rich, light, dry soil, and, from the length of its tap-root, requires a considerable depth. The white beet is an excellent root, and is preferred by many to the larger and more common intermediate varieties. It has been lately in great repute in France and Belgium for the manufacture of sugar. It is not commonly cultivated in our gardens, and we only notice it as being, with the red beet, the parent of those varieties which have been introduced into field culture.

The common field-beet for cattle, which has been long known in Germany, was introduced into England at the latter end of the last century; and its introduction is generally attributed to the late Dr. Lett-som, a physician of great reputation, and one of the Society of Friends. The German name is *mangold wurzel*, or *mangold root*, but it is commonly pronounced *mangel wurzel*, which means *scarcity root*; and by a strange translation it is called in French *racine d'abondance*, or root of *plenty*, as well as *racine de disette*, or root of *scarcity*. The name of *field-beet* is much more appropriate.

The improved varieties of this beet, which grow to a very large size in good soil, have a red orange skin, and when cut through appears veined with red or yellow, in concentric circles. The principal part of the root, which is either long or round in shape, rises often a foot and more above the ground, and the leaves, which are large and succulent, spring from the crown of the root. There is a limit, however, beyond which the root does not improve in quality as it increases, and the roots of a moderate size contain more saccharine and nutritive matter in the same bulk than the larger. This is particularly the case with those varieties from which sugar is extracted. The soil best adapted for the beet-root is a good loam, naturally rich, or made so by repeated manuring. The manure should be well incorporated with the soil, and what is added for this crop should be well rotted and ploughed in deep. The application of liquid manure during the growth of the plant greatly

increases the roots; but it is also said to make them more watery, and for the sugar beet it is not recommended. The seed, which should be chosen from the most perfect plants, is sown in April or May: if sown sooner, there is some danger from the frosty nights which often occur about the beginning of that month; or if the spring is warm and genial, it gets too forward, and instead of increasing in the root, it shoots up a seed-stalk, and the root becomes comparatively useless. If it is sown later than May, it never arrives at a full size before the approach of winter: hence the last week in April or first in May is the best time in our climate. It is found by experience that those plants of beet which grow from seed sown where they are to remain have larger roots, in general, than those which are transplanted; the seed is therefore usually drilled, or dibbled, in rows about thirty inches distant; the seeds are put in less than an inch deep, and when they are dibbled, the holes are about 15 or 18 inches asunder, and two or three seeds are put in a hole. After they come up and are out of danger of frost or insects, they are thinned out, so as to leave the plants at that interval apart. Where the plants have failed, the intervals are filled up by transplanting some of those which are superfluous in other parts: in doing this it is essential that the fibres of the roots be not torn off in pulling up the plant; and if they are taken up carefully with some of the mould adhering to the roots, it will well repay the additional trouble. If the ground is well prepared, there is little fear of the plants not coming up, or of their being destroyed by the fly, as is too often the case with turnips. A sprinkling of liquid manure along the rows, about the time that the plants first appear above ground, will in general secure an abundance of them; and this may be done with much less trouble than would be imagined, by those who have never practised it. It requires only a water-cart, with a large cask and two leathern hose, kept at a proper distance from each other by a stick between them, so that they may pour the liquid manure over two rows at once. If the field be not above a mile from the tank, a man and horse will water two acres in a day, and if the distance is half a mile, four acres; the expense will be amply repaid in the crop.* Putting the seed in with liquid manure is now not an uncommon practice; and a liquid manure drill, invented by Mr. Chandler of Aldbourne, near Hungerford, is largely used for that purpose; and even where it is not the practice to sow liquid manure with the seed, it is well to moisten the seed for a day or two before sowing in order to ensure early germination.

On a very large scale the practice of watering during the early growth of the plant may not be so practicable; but wherever a field of beet is near the home-stall, the evident advantage of it will soon remove any objection arising from trouble or expense. When the plants are three inches above ground, they may be thinned out, the intervals between the rows may be stirred with the plough, grubber, or horse-hoe, and the intervals from plant to plant in the row with the hand-hoe. The ground cannot be kept too fine and open, provided the soil be not extremely porous. It is a common practice to throw the earth from the rows against the roots; but the most experienced cultivators do not approve of the method; on the contrary, they recommend drawing the earth from the plants, or at least laying the whole ground level. Where the soil is naturally rich and deep, the drills may be made on the level ground; but if the soil is shallow, or the subsoil of a barren nature, it is best to raise small ridges, as is done for turnips on the Northumberland plan, and bury the dung under them, by which means the roots have more room to strike downwards. As soon as the outer leaves begin to droop, they may be gathered and given to cattle, but as the roots will not increase except by the aid of the leaves, they should not be stripped until they are on the point of withering. This practice of gathering the leaves is strongly recommended by some, and they assert that the root does not suffer in the least, although the leaves are reproduced; but here we would give this caution, founded on experience and observation. The drooping leaves, if not gathered, will decay and fall off; they have performed their office, and therefore to gather them before they wither is a real economy: but to strip off fresh and growing leaves must injure the plant, and the juices required to replace them are so much taken from the growth of the roots. When fodder is very scarce this may be a sacrifice worth making, but if the object is to reserve the roots for winter food, the leaves should remain on the plant as long as they look fresh and growing, until near the time of taking up the whole crop: the top may then be cut off an inch above the crown of the root, and will be excellent food for the cows and pigs.

The roots are generally taken up and stored for winter, some time before there is any danger of considerable frost. They are stripped of their leaves and thrown into carts, without their roots being cut, or much care taken to clean them, and thrown into heaps, which if large should have such means of ventilation, as a faggot thrust in to the midst of them at top will afford. The heaps are then covered with straw and earth and left for the winter. Or the roots may be piled between hurdles, placed six feet apart from one another, the interval

* If the water-cart contains 100 gallons, it will water one-third of an acre in rows of three feet distance; the horse will go over one mile and a half in an ordinary shaped field to water an acre, to which must be added twice the distance from the tank, taken three times. This makes in all $1\frac{1}{2} \times 6$, or $7\frac{1}{2}$ miles for each acre, when the distance is one mile.

being filled with them, and piled up and thatched over, a faggot being inserted every eight feet. And where several such heaps are placed along side at one or two feet apart, the bushy eaves of a rough thatching interlocking over the interval affords sufficient protection from the weather—the intervals themselves should be also filled with straw, and the whole of the heaps fenced round and protected in a similar manner. In the case of earthing over the heaps, the roots should be put in dry, and some time allowed for a slight fermentation, and the steam produced allowed to escape before the heap is finally covered in, and they will come out quite fresh and juicy till late in the spring; but if the proper precautions are neglected, they will often rot or become musty, and then the cattle will not readily eat them. There are few crops so valuable for winter food for cattle as the beet; Swedish turnips, or ruta бага, exceed them in the quantity of nourishment, weight for weight, but on good light soils the produce of the beet per acre is much greater. On old pasture ground trenched up enormous crops of mangel wurzel have been raised. When the Regents Park was forming, a part which had been trenched was sown very thick with mangel wurzel seed, and such was the produce, that it was sold by auction, in lots, to the cow-keepers in the neighbourhood, at the rate of 80% per acre.

For bullocks also they are excellent; for horses Swedish turnips are preferable. The proportional value of hay, potatoes, Swedish turnips, and beet in feeding cattle, according to Einhof, whose statements Thaer has found to agree with his experiments, is as follows:—18 tons of mangel wurzel are equal to 15 tons of ruta бага, or $7\frac{1}{2}$ tons of potatoes, or $3\frac{3}{4}$ tons of good meadow hay, each quantity containing the same nourishment: but the roots may be grown upon less than an acre, whereas it will take two or three acres of good meadow-land to produce the equivalent quantity of hay; and of all these root crops the least exhausting for the land is the beet. Professor Johnston gives their composition as follows, taking a rough average of several varieties:—

Water	85	per cent.
Gum	0.5	"
Sugar	10	"
Nitrogenous ingredients	0.4	"
Fibre, &c.	4	"
	99.9	

Dr. Völcker states in Morton's 'Cyclopædia' that the

Flesh-forming ingredients amount to	1.8	per cent.
The heat-giving ingredients to	11.2	"
The ash, to about	1	"
And the water to	86.0	

The ingredients of this ash are in such proportion, that each ton per acre removes from the soil, according to Professor Way, the following quantities of

	In the Bulb. lbs.	In the Leaf. lbs.
Potash	4.99	7.86
Soda	3.02	2.52
Lime	0.41	3.31
Magnesia	0.43	3.27
Oxide of iron	0.12	0.52
Phosphoric acid	0.66	1.94
Sulphuric acid	0.65	2.20
Chloride of Sodium	5.29	12.82
Silica	0.54	0.76
	16.11	35.20

The noticeable feature in these figures is the quantity of chloride of sodium present, and it is a fact borne out by large experience, that this common salt is a useful application along with the manure to the mangold wurzel crop.

The white beet has been chiefly cultivated for the extraction of sugar from its juice. It is smaller than the mangold wurzel, and more compact, and appears in its texture to be more like the Swedish turnip. We have given it to cattle, and are satisfied with the result; but we have not made sufficiently accurate experiments to decide which sort is the most advantageous. It will probably be found that the nature of the soil will make the scale turn in favour of the one or the other; but for the manufacture of sugar, the smaller beet, of which the roots weigh only one or two pounds, are preferred by Chaptal, who, besides being a celebrated chemist, was also a practical agriculturist, and a manufacturer of sugar from beet-root.

This manufacture sprung up in France in consequence of Bonaparte's scheme for destroying the colonial prosperity of Great Britain by excluding British colonial produce. It having been found that from the juice of the beet-root a crystallisable sugar could be obtained, he encouraged the establishment of the manufacture by every advantage which monopoly and premiums could give it. Colonial sugar was at the enormous price of four and five francs a pound, and the use of it was become so habitual, that no Frenchman could do without it. Several large manufactories of sugar from beet-root were established, some of which only served as pretexts for selling smuggled colonial sugar as the produce of their own works. Count Chaptal, however,

established one on his own farm, raising the beet-root, as well as extracting the sugar. We here give a brief account of the process, taken chiefly from his own publications, especially the work entitled 'La Chimie appliquée à l'Agriculture,' 2 vols. 8vo, Paris, 1829. The first operation is to clean the roots: some effect this by washing, but Chaptal prefers scraping and paring them with a knife, although by this means one-sixth part of the root is wasted, as the scrapings mixed with earth cannot be safely given to cattle, and even the pigs eat but little of it; but it adds to the manure, and is therefore not altogether lost. Six tons of beet-root are thus reduced to five, which are next to be rasped and reduced to a pulp. This is done by a machine consisting of a cylinder of tinned iron, two feet in diameter, and eighteen inches in the axis, on which it is turned by machinery. On the circumference of this cylinder are fixed, by means of screws, ninety narrow plates of iron, rising three-fourths of an inch from the surface and parallel to the axis, at equal distances all round; the outer or projecting edges of these plates are cut into teeth like a saw; a slanting box is fixed to the frame on which the axis of the cylinder turns, so that the roots may be pressed against these plates. The cylinder is made to revolve rapidly, and the roots are thus scraped, the pulp falling into a vessel, lined with lead, placed below. When two such cylinders are made to revolve 400 times in a minute by a sufficient power, whether water, wind, or horses, two and a half tons of roots are ground down in two hours. It is necessary that this operation should proceed rapidly, or else the pulp acquires a dark colour, and an incipient fermentation takes place, which greatly injures the future results. As the pulp is ground it is put into strong canvas bags, and placed under a powerful press to squeeze out the juice. The residue is stirred, and subjected to a second and third pressure, if necessary, till every particle of juice is extracted. As the liquor is pressed out, it runs into a copper, until it is two-thirds filled. The strength is ascertained by an instrument similar to the saccharometer used by brewers, called the *pèse-liqueur* of Beaumé,* which shows the specific gravity of the liquid. The fire is now lighted, and by the time the copper is full the heat should be raised to 178° of Fahrenheit's thermometer (65° of Réaumur), but no higher.

In the mean time a mixture of lime and water has been prepared by gradually pouring as much water upon 10lb. of quick lime as will make the mixture of the consistency of cream. This is poured into the copper when the heat is steadily at 178°, and is well mixed with the juice by stirring it. The heat is then increased till the mixture boils, when a thick and glutinous scum rises to the surface. As soon as clear bubbles rise through this scum, the fire is suddenly put out by water poured on it or by a proper damper. The scum hardens as it cools, and the sediment being deposited the liquor becomes clear and of a light straw colour. The scum is then carefully taken off with a skimmer having holes in it, and is put into a vessel till such time as the liquor remaining in it can be pressed out. A cock is now opened about five inches above the bottom of the boiler, and all the clear liquor is drawn off. Another cock lower down lets out the remainder until it begins to appear cloudy; what still remains is afterwards boiled again with what is extracted by pressure from the scum. The clear liquor is now subjected to evaporation in another boiler which is wide and shallow. The bottom is but slightly covered with the juice at first, and it boils rapidly. As the water evaporates, fresh juice is let in. When a certain degree of inspissation or thickening has taken place, so as to show five or six degrees of strength on the *pèse-liqueur*, animal charcoal is gradually added till the liquor arrives at 20°. One hundred weight of charcoal is required for the juice of 2½ tons of beet, which is now reduced to about 400 gallons. The evaporation by boiling continues till the saccharometer marks 25° and a regular syrup is obtained. This is now strained through a linen bag, and the liquor is kept flowing by means of steam or hot air, and assisted by pressure. In two or three hours all the clear syrup will have run through.

There are many nice circumstances to be attended to, which can only be learned by experience, and an outline of the process is all that we undertake to give.

The syrup thus prepared is again boiled and skimmed until it is sufficiently concentrated, which is known in the following manner. The skimmer is dipped into the syrup and drawn out; some of the thick syrup which adheres to it is taken between the thumb and fore-finger and held there till the heat is reduced to that of the skin; the finger and thumb are separated, and if the syrup is of a proper strength, a thread will be drawn out, which snaps and has the transparency of horn or rather barley-sugar: this is called the *proof*. The fire is then put out and the syrup is carried to the cooler, which is a vessel capable of containing all the syrup produced by four operations or boilings. Here the sugar is to crystallise: as soon as this commences the whole is well mixed and stirred, and before it becomes too stiff, earthen moulds, of the well-known sugar-loaf shape, and of the size called *great bastards*, are filled with the crystallising mass, of which a little at a time is poured into each. When they are full, they are carried to the coolest place on the premises. As the crystallisation goes on, the crust formed on the top is repeatedly broken, and the whole is stirred

* The *pèse-liqueur* of Beaume here referred to is an hydrometer, of which 0° corresponds to 1.000, the specific gravity of pure water at 55° of Fahrenheit; and 25° to about 1.215.

till the crystals are collected in the centre; it is then allowed to go on without further disturbance. In three days it is so far advanced, that the pegs which were put into the holes at the point of the moulds may be taken out and the molasses allowed to run out. In a week this is mostly run off. White syrup is now poured on the top of the moulds, which filters through the mass and carries part of the colouring matter with it. The process that follows is exactly that in common use in refining West India sugars.

Although most of the operations are nearly the same as those by which the juice of the sugar-cane is prepared for use, much greater skill and nicety are required in rendering the juice of the beet-root crystallisable on account of its greater rawness, and the smaller quantity of sugar that it contains. But when the sugar is refined, it is impossible for the most experienced judge to distinguish it from the other, either by the taste or appearance; and from this arose the facility with which smuggled colonial sugar was sold in France, under the name of sugar from beet-root. Five tons of clean roots produce about 4½ cwt. of coarse sugar, which give about 160 lbs. of double-refined sugar, and 60 lbs. of inferior lump-sugar. The rest is molasses from which a good spirit is distilled. The dry residue of the roots, after expressing the juice, consists chiefly of fibre and mucilage, and amounts to about one-fourth of the weight of the clean roots used. It contains all the nutritive part of the root, with the exception of 4½ per cent. of sugar, which has been extracted from the juice, the rest being water. Two pounds of this dry residue and half a pound of good hay, are considered as sufficient food for a moderate-sized sheep for a day, and will keep it in good condition; and cattle in proportion.

As the expense of this manufacture greatly exceeds the value of the sugar produced, according to the price of colonial sugar, it is only by the artificial encouragement of a monopoly and premiums that it can ever be carried on to advantage. The process is one of mere curiosity as long as sugar from the sugar-cane can be obtained, and the import duties laid upon it are not so excessive as to amount to a prohibition; and in this case it is almost impossible to prevent its clandestine introduction.

By allowing the juice of the beet-root to undergo the vinous fermentation and by distilling it, a more profitable result will be obtained in a very good spirit. A kind of beer may also be made of it, which is said to be pleasant in warm weather and wholesome.

Another mode of making sugar from beet root, practised in some parts of Germany, is as follows, and is said to make better sugar than the other process. The roots having been washed are sliced lengthways, strung on packthread and hung up to dry. The object of this is to let the watery juice evaporate, and the sweet juice, being concentrated, is taking up by macerating the dry slices in water. It is managed so that all the juice shall be extracted by a very small quantity of water, which saves much of the trouble of evaporation. Professor Lampadius obtained from 110 lbs. of roots 4 lbs. of well-grained white powder-sugar, and the residuum afforded 7 pints of spirit. Achard says that about a ton of roots produced 100 lbs. of raw sugar, which gave 55 lbs. of refined sugar, and 25 lbs. of treacle. This result is not very different from that of Chaptal.

The production of a spirit by fermentation and distillation from the juices of the beet is now a very extensive manufacture on the continent, and it is sought to introduce it into this country. The question on which its profitableness here must hinge is this: are beet-roots grown in an English climate as full of saccharine juice as those grown under the warm sun of France? We imagine not; and it is extremely doubtful if any more profitable way of using the land set apart for this crop exists in this country than that of sowing seed of the largest sorts for the growth of food for the production of milk and beef and mutton.

Meanwhile we add the following paragraph descriptive of one of the processes adopted, though Champonnois' and other patent methods of extracting the spirit exist.

Lepay's system of distilling from beet-root consists in fermenting the juice, while still in slices, of the root, and in passing over heated steam, through vessels full of these slices, after the fermentation is completed. Mr. Weeks, of Bolney Lodge, Sussex, states in the 'Times' that, during the last season nearly 5000 tons have been distilled in this country on this plan, yielding 40,000 gallons of proof spirit. The refuse is nutritive, and he says that his experience of the steamed roots after distillation is conclusive on this point. "Some Cull South-down lambs I purchased on July 5th last, at 12s. 6d. each, and sold last week, fatted almost entirely on the steamed roots, at 38s. each, after taking a better fleece of wool than usual. Nor could I have fatted them so well on any other produce. And in so steaming the roots is it not better to catch the steam and condense it into spirit than let it go up the chimney to evaporate in the air?" It is only right to add that the subject is properly one for experiment, the view thus expressed not being so self-evident as it is here implied to be. The steam carries off that which in the original root contributes to its nutritive character, the fermentation having conferred an evaporable character upon it; and French grown roots, grown under a somewhat different climate, contain probably more of this spirit-yielding portion of the root than our own. The recently published official report on the experiments of the past year declares them to have hitherto failed to yield a profitable spirit.

BEG, also pronounced BEY, is a Turkish word which signifies "prince, lord, or chief," and in the Ottoman empire is rather vaguely used as a title of governors and other high officers of the state. It is also frequently subjoined to proper names, to distinguish persons of high rank generally.

BEGGAR. [PAUPERISM AND POOR-LAWS.]

BEGLERBEG, a compound word, which properly signifies "chief of chiefs," and the title of the governor-generals of the provinces. They stood next in rank to the vizir, and had under their jurisdiction many *sanjaks*, or districts, with their begs, agas, &c. One of their external distinctions was that the sultan of Constantinople always bestowed on them three ensigns, named in Turkish *tugh*, which consisted of staves trimmed with the tail of a horse: inferior officers of the crown were honoured by only one or two of these insignia. About the middle of the 17th century the Turkish empire comprised twenty-two *beglerbeglics*, or provinces governed by beglerbegs; these were subsequently reduced to three,—Roumelia, Anatolia, and Damascus,—and are now discontinued. The governors of the various provinces are pashas of two tails only. (Ubicini, 'Lettres sur la Turquie.')

BEGUINS, in ecclesiastical history, certain tertiaries or half-monks, who followed the *third* rule of St. Francis. They were called in Italy, Bizochi and Bocasoti; in France, Beguins; and in Germany, Beguards or Beghards; and are mentioned in ecclesiastical history of the middle age as early as the 11th century. The accounts however which both ancient and modern writers generally give of these famous names are so uncertain and so different from each other, that the history of the Beghards and Beguins is involved in greater perplexity than any other part of the ecclesiastical history of that period. Mosheim is minute upon the true origin of these denominations, both of which he considers to have been derived from the German *beggen*, or *beggeren* (now written *begehren*), to seek with importunity, by joining which to the syllable *hard*, which is the termination of many German words, we have the word *beggehard*, applicable to a person who asks any thing with great ardour, and from which the English word *beggar* is manifestly derived. These observations, on the origin and signification of the words in question, serve as a clue to the difficulties in which the history of the Beghards and Beguins has been involved; and, as Mosheim justly observes, will enable the reader to account for the prodigious multitudes of Beghards and Beguins which sprung up in Europe in the 13th century; and will show him how it happened that these denominations were given to above thirty sects or orders, which differed widely from each other in their opinions, their discipline, and manner of living. The Bizochi or Beguins, if we except their sordid habit and certain observances or maxims, which they followed in consequence of the injunctions of St. Francis, lived after the manner of other men, and were therefore considered in no other light than as seculars and laymen. (See the 'Acta Inquisit. Tholosanæ,' published by Limborch, pp. 307, 329, 382, 389, &c.; and Jordan's 'Chronicon,' published by Muratori, 'Antiquit. Ital. Medii Ævi,' tom. iv. p. 1020.)

We must not, however, says Mosheim, confound these Beguins and Beguines, who derive their origin from an austere branch of the Franciscan order, with the Beguines of the Netherlands, and afterwards of Germany, who crept out of their obscurity in the 13th century, and multiplied prodigiously in a very short time. Their origin was of earlier date than this century, but it was only now that they acquired a name and made a noise in the world. Their primitive establishment was undoubtedly the effect of virtuous dispositions and upright intentions. A certain number of pious women, both virgins and widows, in order to maintain their integrity, and preserve their principles from the contagion of a corrupt age, formed themselves into societies, each of which had a fixed place of residence, and was under the inspection and government of a female head. Here they divided their time between exercises of devotion and works of industry, reserving to themselves the liberty of entering into the state of matrimony, and quitting the convent whenever they thought proper. And as all those among the female sex who made extraordinary professions of piety and devotion were distinguished by the title of *Beguines*,—that is, persons who were uncommonly assiduous in prayer,—that title was given to the women of whom we are now speaking. The first society of this kind that we read of was formed at Nivelles in Brabant, in the year 1226, or, as other historians say, in 1207, and was followed by so many institutions of a like nature in France, Germany, Holland, and Flanders, that towards the middle of the 13th century there was scarcely a city of any note that had not its *beguinage*, or vineyard, as it was sometimes called in conformity to the style of the 'Song of Songs.' All these female societies were not governed by the same laws; but in the greatest part of them, the hours that were not devoted to prayer, meditation, or other religious exercises, were employed in weaving, embroidering, and other manual labours of various kinds. The poor, sick, and disabled Beguines were supported by the pious liberality of such opulent persons as were friends to the order.

In the 14th century the societies of the Beguines had become very numerous in Germany; but as they adopted some of the mysterious and extravagant opinions of the "Mystic brethren and sisters of the free Spirit," we find in the German records of this century a frequent distinction of them into those of the right and approved class and those of the sublime or free spirit, the former of whom adhered to the public religion, while the latter were corrupted by the opinions of the mystics.

The Beguines now shared in the persecution which fell upon the mystics. The Clementina, as it is called, or constitution of the council of Vienna, A.D. 1311, against the Beguines, or those female societies who lived together in fixed habitations, under a common rule of pious discipline and virtuous industry, gave rise to a persecution of these people which lasted till the Reformation by Luther, and ruined the cause both of the Beguines and Beghards in many places; for though the pope, in his last constitution, had permitted pious women to live as nuns in a state of celibacy, with or without taking the vow, and refused a toleration only to such of them as were corrupted with the opinions of the Brethren of the free Spirit, yet the vast number of enemies which the Beguines and Beghards had, partly among the mechanics, especially the weavers, and partly among the priests and monks, took a handle from the Clementina to molest the Beguines in their houses, to seize and destroy their goods, to offer them many other insults, and to involve the Beghards in the like persecution. Pope John XXII. afforded the Beguines some relief under these oppressions, in the year 1324, by a special constitution, in which he gave a favourable explanation of the Clementina, and ordered that the goods, chattels, habitations, and societies of the innocent Beguines should be preserved from every kind of violence and insult, which example of clemency and moderation was afterwards followed by other popes. On the other hand, the Beguines, in hopes of disappointing more effectually the malicious attempts of their enemies, embraced in many places the third rule of St. Francis and of the Augustines. Yet all these measures in their favour could not prevent the loss both of their reputation and substance, for from this time they were oppressed in several provinces by the magistrates, the clergy, and the monks, who had cast a greedy eye upon their treasures, and were extremely eager to divide the spoil. (See Mosheim's 'Eccles. History,' edit. 8vo, Lond., 1782, vol. iii., pp. 228, 229, 230, 231, 337, 379.) Mosheim intended a separate work upon the Beghards and Beguines, which never appeared, though he states himself, in his history, that it was then almost finished. The most copious writer on the long persecution of the Beguines is Christianus Wursten, or Urtisius, in his 'Chronicon Basiliense,' written in German, lib. iv., cap. ix., p. 201, fol., Basil, 1580.

There is a little work of great rarity, entitled 'Lettre de M. l'Abbé S *** à Mlle. de G ***,' Béguine d'Anvers, sur l'Origine et le Progrès de son Institut,' 12mo, Par., 1731, from which we learn that Beguinages, as they were called then, existed in more than forty towns of the Netherlands and the adjacent countries on the Rhine. It contains also two representations of a Beguine, one in the dress worn in the chapel of her house or convent, and the other in her walking habit. Communities of Beguines still subsist in Holland, Belgium, and Germany. Each house is governed by a prioress, who alone can permit or direct any of the sisters to go forth. A novitiate of three years is required before novices are admitted into the order, after which they assume the habit and take the vow, which consists only of a promise of chastity while they continue in the order, which however they are at liberty to leave when they think proper. The occupation of the Beguines is the education of young females and attendance on the sick, both in their private residences and in the public hospitals. Their principal establishment is now at Ghent, and numbers 600 inmates, the total number in Belgium being estimated at 6000. Their dress is black, with white veils; but that of the novices is varied, and those who have just taken the veil wear chaplets round their heads.

BEHEADING. [DECAPITATION.]

BEHEMOTH. [HIPPOPOTAMUS, IN NAT. HIST. DIV.]

BEIT is an Arabic word, which properly signifies a tent or hut, but is likewise employed to denote any edifice or abode of men. It is often found as a component part of proper names in the geography of those countries that have become subject to the Arabs: *Beit-al-Harâm*, 'the sacred edifice,' or 'the edifice of the sanctuary,' a designation frequently given to the temple of Mecca; *Beit-al-Mukaddas*, 'the sanctified abode,' Jerusalem; *Beit-al-Fakih*, 'the abode of the jurist,' a town in Yemen, &c. The Hebrew word, corresponding to the Arabic *Beit*, is *Beth*, which we find employed in a manner perfectly analogous in the Old Testament: in the name *Bethlehem* (in Arabic *Beit-Lahm*, or *Beit-al-Lahm*), 'the house of bread'; *Beth-Togarmah*, 'the house of Togarmah,' Armenia. The same word, *Beth*, is in Syriac still more extensively used as a component part of geographical names. In Arabian poetry, *Beit* signifies a distich.

BELED, or BALAD, is an Arabic word, which signifies a town, a province, or country, and is met with as a component part of many proper names in Oriental geography, for example, in Biledulgorid, which properly is *Balad-al-Jarid*, the 'country of palm-trees.'

BELFRY, that part of a church-tower or steeple in which the bells are hung. The term is applied not only to that part of the tower, but also to the framing on which the bells are suspended. Belfry is probably derived from *belfredus*, a low Latin term of the middle ages, a compound of *bell* a Teutonic word, and *freid* (*freide*), peace, (Ducange, 'Gloss.') The old French word is *belfroit*. (Johnson's 'Dict.' by Todd.) Ducange gives also the forms *beaufroy* and *bellefroy*, and Viollet le Duc those of *baffraiz*, or *belfroi*, which latter word is used at the present day by French writers on architecture. Belfry is synonymous with *campanile* [CAMPAILE], which, with the terms *clocaria* and *tristegum*, was used by the writers of the middle ages to express the same thing. According to some, the name *belfredus* was applied to a

wooden tower used in attacking fortified places, and it was afterwards given to any elevated tower in which a bell was hung. This state-

Plan of the Belfry of St. Paul's.
A and B, lines of sections; a, a, beams.

ment, if correct, might lead us to infer that the Latin word *bellum* (war) was the first part of the compound *belfredus*, and the second

Section of the belfry of St. Paul's on the line A, A
c, c, gudgeons, on which the bell swings.

Section of the belfry of St. Paul's on the line n, n.
h, hammer.

Scale of 0 1 2 3 4 5 10 20 Feet.

part possibly derived from the Latin *fero*, to bear or carry away. The forms *belfredus*, *verfredus*, and *beffroi*, also occur as the names of old military engines, and seem to lead to a different etymology.

In this plan and sections of the belfry of St. Paul's church are seen the construction of the timbers, showing their bearings independent of the masonry. This construction may be taken as a good example of the method of hanging heavy bells in a belfry. In the two towers of St. Paul's Church four bells are hung; in the southern tower three, and in the northern tower one. The great bell shown in the section is hung over two others in the south tower; these latter are fixed, and are not intended to be rung: the upper bell is hung on gudgeons or axles, and prepared for ringing, but from the confined space in which it is placed, it cannot be rung, and only moves on its axle when struck by the hammer of the clock.

In constructing a belfry, the frame-work is placed either on stone corbels, or is made to bear on a "recess formed in the wall." ('Encyc. Method. Arch.') This latter method is considered the best, because the vibration caused by the motion of the bells acts with less force on the masonry than it would if the framework were fixed in the masonry. It is also to be observed, that the higher the bells are placed in the tower, the more must the vibration, caused by ringing them, affect the masonry.

Village churches have belfries in their towers or steeples. In some instances, where there is a single bell, it is not placed in a tower, but suspended to a slight frame-work fixed between an arch constructed on the exterior top of the gable end of a church or chapel, which is either called a *bell cot*, in mediæval architecture, or a *bell gable* in modern pseudo-classical art. [BELL.]

BELGÆ, the general name given by Cæsar to the different tribes inhabiting the north of Gaul, between the sea on the west, the rivers Matrona (Marne) and Sequana (Seine) on the south, and the Rhenus (Rhine) on the east. But it is not well determined how far this name may be extended to the east; perhaps the Treviri, on the banks of the Moselle, were included. Cæsar remarks that the Matrona and Sequana separate the Belgæ from the Galli, who were to the south of them. He says also, in general and vague terms, that the Belgæ extend to the Lower Rhine, and lie towards the north and the rising sun. He also ('De Bell. Gall.' v. 24) uses the term *Belgium* to express the country of the Belgæ. The Belgæ were, according to Cæsar's testimony, of German origin, though probably wanting a name: to the inhabitants north of the Seine, he applied the name of some of the more considerable of the tribes to the whole. It would rather seem that the bulk of the people were of Celtic origin. Cæsar was informed by the Remi ('De Bell. Gall.' ii. 4) that most of the Belgæ were Germans, who had crossed the Rhine, and had expelled the Gauls. But this only applied to some of the tribes; and others, the Morini for instance, whose name is but a variation from that of *Armorici*, were Celts. All were distinguished by their warlike character, which Cæsar attributes partly to their origin and partly to their being strangers to luxury and refinement. The Bellovaci were the most warlike and numerous Belgic tribe in the time of Cæsar. ('De Bell. Gall.' ii. 4.) The Remi, whose capital was Durocortorum (Rheims), were the nearest Belgic tribe to the Galli on that side. The rest of the tribes are mentioned by Cæsar (ii. 4); among them we find one name, the Atrebatæ, the same as that of a tribe in Britain. The Belgæ may be described generally as occupying, in the time of Cæsar, the French departments of Nord, Pas de Calais, Somme, Seine Inférieure, Oise, and Aisne; with a part of modern Belgium.

When Cæsar invaded South Britain, he found that part of the island occupied by Belgæ, that is, by tribes of German origin, who had passed over from the opposite shores of Gaul, and obliged the original inhabitants to retreat into the interior of the country. ('De Bell. Gall.' v. 12.) But as he had no intercourse with the original inhabitants, it is impossible to say how far the Belgæ had penetrated inland; and later historians have given us no account of this circumstance. We learn only that the whole southern coast, from Suffolk to Devonshire, was occupied by Belgic tribes. The Cantii were settled in Kent, the Trinobantes to the north of the Thames, the Regni in Sussex, and the Atrebatii in Berkshire. To the west of them the Belgæ, properly so called, occupied Hampshire and Wiltshire, and extended through Somersetshire to the Bristol Channel; their capital was Venta Belgarum, Winchester. Farther to the west, the Durotriges were found in Dorsetshire, and their neighbours, the Damnonii, in Devonshire. This is taking the accounts of Cæsar and of Ptolemy together; Cæsar fixes the Belgæ in Kent and Sussex, Ptolemy in Hampshire, Dorsetshire, Wiltshire, and Somersetshire; but Wiltshire, by its ancient remains, shows that it was essentially Celtic. The names of these chief towns go far to show they were not German; Venta (Winchester), and Ischalis (Ilchester), are British: and Aquæ Solis (Bath) is Latin.

The Belgæ in Britain were most likely rather of the Celtic division of the Belgæ, than of the German; and, conformably to the character of their brethren in Gaul, made a stout resistance to Cæsar. But about a century afterwards they were compelled to submit to the yoke, which the Romans had already in the time of Cæsar imposed on their kinsmen in Gaul. The name *Belgica* occurs as the name of a division of Gaul as late as Diocletian's time. Under the emperors it was governed by an officer with the title of Procurator, or Legatus.

BELIAL, usually Béliat, more correctly Belial, *Belial*, בְּלִיָּאל (pronounce B'liyálgal), is one of the few compound words in the Hebrew language. It is formed of בְּלִי *nothingness, not*, and יָל *utility, advantage*. Hence Belial means a worthless fellow. A man of Belial, or a son of Belial, a daughter of Belial, mean in the Bible a wicked person. Belial, if emphatically used, means the worst of spirits. Thus in the passage, "What concord hath Christ with Belial?" 2 Cor. vi. 15. Compare Milton's 'Paradise Regained,' book ii. 147-152:—

"So spake the old serpent doubting, and from all
With clamour was assured their utmost aid
At his command; when from amidst them rose
Belial, the dissolute spirit that fell,
The sensuallest, and, after Asmodai,
The fleshliest incubus, and thus advised."

Others have endeavoured to derive the word from עָלָה *to act*, so that Belial should be *a not acting one, an idle fellow*; others from עָלָה *to rise*, so that Belial should be one who should finally be cut down, *not to rise again*. The Talmudists in Sanhedrin, fol. 111, derive the word from עָלָה or עָלָה *yoke*. According to them, Belial is *without a yoke, without restraint and discipline*. Compare Pfeiffer's 'Opera,' 1704, tom i. p. 503.

BELL; BELL FOUNDING. Whatever may have been the origin of these useful implements, bells of small size are undoubtedly very ancient. Small gold bells, intermixed with pomegranates, are mentioned as ornaments worn upon the hem of the high priest's robe, in Exodus chap. xxviii. v. 3, 4; and Calmet says that both were worn in the same manner by the kings of Persia. Among the Greeks we find hand-bells used in camps and garrisons. Plutarch mentions the use of the bell in the Grecian fish-market. The Romans had three chief appellations for the little bell, *petasus, codo, and tintinnabulum*. The hour of bathing among the Romans was announced by a bell, which was thence called by Martial *as thermarum*: it was also in domestic use; was adopted, both as an ornament and an emblem, upon triumphal cars; and was fastened to the necks of cattle, that they might be traced when they strayed, particularly to the necks of sheep.

The large bells now used in churches are said to have been invented by Paulinus, bishop of Nola in Campania, about the year 400, whence the Nola and Campana of the lower Latinity. They were probably introduced into England very soon after their invention. They are first mentioned by Bede, about the close of the 7th century. Ingulphus records that Turketul, abbot of Croyland, who died about the year 870, gave to that abbey a bell of very large size, which he named Guthlac. His successor Egelric cast a ring of six others, to which he gave the names of Bartholomew, Bettelin, Turketul, Tatwine, Pega, and Bega. Pope John XIII., A.D. 968, consecrated a very large new cast bell in the Lateran Church, and gave it the name of John. The ritual for the baptising of bells may be found in the Roman Pontificale.

Sir Henry Spelman, in his 'Glossary' v. 'Campana,' has preserved two monkish lines on the subject of the ancient offices of bells:

"Laudo Deum verum, Flebem voco, congreco Clerum,
Defunctos ploro, Pestem fugo, Festa decoro."

And Brand quotes other monkish rhymes, which enumerate no less than sixteen purposes to which bells are, or may be, applied.

The *Couvre-feu*, or *Curfew Bell*. [CURFEW.]

The *Passing Bell* was so named, as being tolled when any one was passing from life. Hence it was sometimes called the *Soul Bell*; and was rung that those who heard it might pray for the person dying, and who was not yet dead. The number of times of tolling depended in some measure on the rank of the person. This practice is of high antiquity in England. We have a remarkable mention of it in the narrative of the last moments of the Lady Katherine (sister of Lady Jane) Grey, who died a prisoner in the Tower of London, in 1567. (Ellis's 'Letters.') The tolling of the passing bell certainly continued in use as late as the times of Charles II.

A *Sanctus*, or *Saint's-bell*, was so called, because it was rung when the priest came to those words of the mass, *Sancte, Sancte, Sancte Deus Sabaoth*, that all persons who were absent might fall on their knees, in reverence of the holy office which was then going on in the church. It was usually a small bell rung by hand, similar to those still in use in Roman Catholic churches, but it was also frequently placed where it might be heard farthest, in a lantern at the springing of the steeple, in a turret at an angle of the tower, or for the convenience of being more readily and exactly rung, within a cote or turret, between the church and the chancel; the rope in this situation falling down into the choir not far from the altar. Several of these turrets, and some with the bells in them, are still to be seen in our country churches.

Hawkins and Burney both mention the skill of English bell-ringers. The latter quotes from 'Tintinnalogia, or the Art of Ringing,' published in 1668; a work, he assures us, not beneath the notice of musicians who wish to explore all the regions of natural melody; as in this little book they will see every possible change in the arrangement of diatonic sounds, from two to twelve; which being reduced to musical notes,

would point out innumerable passages, that, in spite of all which has hitherto been written, would be new in melody and musical composition. In the art of ringing, however, melody has never been studied; mechanical order and succession have been all in all. The treatise on this subject at present in highest repute is 'Campanologia Improved, or the Art of Ringing made easy,' 3rd edit. 12mo. Lond. 1733, where the reader will find all the terms explained of single, plain bob, grandsire bob, single bob minor, grandsire treble, bob-major, caters, ten-in or bob royal, cinques, and twelve-in or bob maximus, with all their regular permutations. Further information of a practical nature, as well as generally interesting, may be found in the Rev. Alfred Gatty's work, 'The Bell; its Origin, History, and Uses;' and in Mr. E. B. Denison's 'Lectures on Church Building; with some Practical Remarks on Bells and Clocks.'

The tone emitted by a bell depends conjointly on the diameter, the height, and the thickness; the thinner bell yielding the lower note, other things being equal. There is a sort of rule among German bell-founders, whereby the various dimensions are always to bear certain ratios to each. The thickest part, where the hammer strikes, is called the 'sound bow.' If this thickness be called = 1, then the diameter of the mouth = 15, the diameter of the top = $7\frac{1}{2}$, the height = 12, and the weight of clapper = $\frac{1}{40}$ th the weight of bell. According to the value of the unit in this formula, so will be the musical pitch of the tone yielded by the bell. English founders have each rules for himself. There are, however, occasionally great difficulties in ensuring any desired pitch in the tone of a bell; thus, the bell of the new Royal Exchange has never realised the expectations of its producers, either in pitch or quality of tone. During a lengthened discussion before the Institution of British Architects, in 1855, Mr. Denison illustrated the differences between those sounding bodies which are shaped like ordinary bells, and those which assume the forms of springs, spirals, hemispheres, forks, and gongs. Many of these yield deep and rich tones; but the ordinary bell, of given weight, throws out its sound to the greatest distance.

Passing from the antiquities to the mechanism of this subject, we may refer to ALLOY for the relative proportions of copper and tin contained in bell-metal, and to FOUNDRING for the broad principles which govern the casting of metals in general. A few details concerning the practical application of these principles to bell-casting will be here given.

The casting of common house-bells or hand-bells differs in nowise from the processes relating to small castings in metal generally; but for church-bells the case is otherwise. The production of a *sonorous* quality, in addition to many of those qualities which pertain to all large castings in mixed metal, gives occasion for many scrupulous arrangements in the management of the foundry. A bell-foundry must have a furnace which will contain many tons of metal, for the whole of the casting for one bell is made at once. In 1835, for instance, Messrs. Mears cast the new Great Tom of Lincoln, intended to replace the old Great Tom; it weighs 12,000 pounds, being somewhat heavier than the great bell of St. Paul's Cathedral; and the whole of this ponderous mass of metal was melted at one time and in one furnace. This Great Tom, though smaller than the bell of St. Paul's, is heavier, on account of its greater thickness. We shall have presently to mention modern bells weighing much more than either of these.

The arrangements as to the central core or mould for casting a large bell are thus made:—Contiguous to the furnace is a pit, deeper than the height of the bell. In the centre of this pit is built up a rough mass of brick-work, somewhat smaller than the interior of the bell; and this is coated externally with a mixture of earth and horse-dung, applied in successive layers, and worked smooth by gauges until the exterior of the core presents exactly the same size and shape as the interior of the intended bell. When the prepared core is thoroughly dried by means of fires, a second coating of composition is laid on, of the same thickness as the intended bell; this coating, which is called the "model," is formed of earth and hair, and is, like the former, brought to a very smooth and correct surface by gauges, the exact counterpart of the exterior of the bell. A third coating is next applied, called the "shell," much thicker than the others, and formed of a somewhat different composition. A little tan-dust is sprinkled on the first coating, or core, before the second, or model, is applied; and also on the latter, before the outer coating, or shell, is laid on. When all is well dried, the "shell" is lifted off from the "model," and the model is picked or cut off from the core piecemeal. If we suppose the core, the model, and the shell to be three hemispherical cups placed one within another, and the middle one to be removed, it will serve to illustrate how a vacant space comes to be formed between the core and the shell; and when we further bear in mind that the exterior of the core gives the internal form to the bell, and the interior of the shell the external form, the object of the whole arrangement will be clearly seen.

This internal cavity of the mould, between the core and the shell, is that into which the metal is to be poured. The casting-pit is filled up with loam or earth, to the level of the top of the mould; a shallow channel is cut in the loam from the furnace to an orifice communicating with the vacant space in the mould; and two other orifices are left for the escape of air as the melted metal enters. Meanwhile the metal is being melted in the furnace. The tin employed is in the form

of blocks, brought from Cornwall; while the copper is old ship sheathing and other fragments. These are melted in a reverberatory furnace, by the heat of billets of wood, a kind of fuel less injurious to the metal than either coal or coke. All being ready, the earth which stops an orifice in the lower part of the furnace is knocked or dug away, a narrow jet instantly pours out from the opening, and a stream of liquid fire (for so it seems to the eye) runs along the channel in the loam, and flows into the mould, bubbling and hissing, and giving forth greenish sparks. When the mould is full, the metal is allowed to remain till perfectly cool; the loam is then removed, the external "shell" lifted or cut from the bell, the bell lifted off the core, and the core pulled down. If the bell be very large, it alone occupies the pit; but if of smaller size, such as from three or four to ten or twelve hundredweights, six or eight may be cast in one pit at one time.

The tone of a bell depends conjointly on the diameter and the thickness; a small bell or a thick bell giving, relatively, a more acute tone than one which is either larger or thinner. Hence the founder regulates the diameter and thickness according to the musical pitch of the tone which the bell is to yield; but as this cannot be rigidly attained by casting only, the bells (say a set to form chimes) are attuned by chipping away some of the metal with a sharp-pointed hammer; reducing the diameter at the lower edge when the tone is too low, and reducing the thickness at the part where the hammer strikes when the tone is too acute.

Many bells of considerable size have been constructed within the last few years. In 1845 Messrs. Mears, of Whitechapel, cast a bell for the south tower of York Minster. It was larger than any other at that time in the United Kingdom, being twelve tons in weight,—seven tons heavier than the Great Tom of Lincoln, and five heavier than the Old Tom of Oxford. The metal took twelve days to cool. The cost was about 2000*l*. This was, however, exceeded in size by one cast by the same founders for the Roman Catholic cathedral at Montreal. This bell is 8½ feet in diameter, and weighs 13½ tons (more than 30,000 lbs.) It required the melting of twenty-five tons of metal to effect the casting. The thickest part of the bell—the "sound-bow," where the clapper or hammer strikes—is eight inches.

The great bell at Westminster (which will probably first begin its regular working in the present year, 1859,) is interesting, not only for its vast size but for the incidents in its history. From its first planning to its completion no less a time than sixteen years elapsed; chiefly owing to the disagreements relating to the great clock with which it is associated. At the northern end of the New Houses of Parliament is the clock tower, a rectangular structure, rising to a height of 300 feet from the ground, or 326 from the foundation. In the centre of this is a shaft more than 200 feet high, with horizontal dimensions of 11 feet in one direction and 8½ feet in the other. Up the interior of this shaft was the only passage through which the great bell could be conveyed; and even then it had to be laid sidewise, that its dimensions might not exceed those of the shaft. The great clock stands at a height of about 160 feet from the ground, and the great bell about 40 feet higher. The bell-room was arranged with all the necessary apparatus for five bells: the greatest was to weigh about 14 tons, was to yield the note E, and was to be hung in the centre; the first quarter bell in one corner, yielding B, and weighing 4½ tons (more than St. Paul's great bell); the second quarter bell in another corner, with a note E♯, and a weight of 2 tons; the third quarter bell in a third corner, yielding F♯, and having a weight of 1½ ton; and a fourth quarter bell in the remaining corner, with a tone of G♯, and a weight of about 1¼ tons. All the five bells together, with their hammers, were estimated at 30 tons; the hammer and lever for the largest bell being alone nearly a ton. The harmonies (or rather melodies) of the quarter bells were thus arranged:—At a quarter-past the hour, G♯ F♯ E B; at half-past, E G♯ F♯ B, E F♯ G♯ E; at three-quarters, G♯ E F♯ B, B F♯ G♯ E, G♯ F♯ E B; and at the hour, E G♯ E B, E F♯ G♯ E, G♯ E F♯ B, B F♯ G♯ E.

Such was the plan laid down many years ago; and the actual results deviate only a little from it. The large bell received for a time the familiar appellation of Big Ben; but the new bell bears the more dignified title of St. Stephen. The bell is suspended from a large wrought-iron beam, two tons in weight, which has been tested by seventy tons' strain, without yielding more than one-fifth of an inch. The (first) great bell, designed by Mr. Denison, was (after a long series of disputes among commissioners, architects, and other persons concerned) cast by Messrs. Warner, at a foundry near Stockton-on-Tees, in August, 1856. The mould had been six weeks in preparation; and there were two furnaces, holding ten tons of metal each. Eighteen tons of metal were poured into the mould, producing a bell about 8 feet high, 9½ feet diameter at mouth, and weighing, when trimmed and adjusted, about 15 tons. Unfortunately, there was some flaw in the metal. The bell was conveyed to London, placed for a time at the foot of the clock tower, and struck for a short time one day in each week, that the public might hear the beauty of the sound. On one of these occasions the E became a dull and uncertain tone; the bell was found to be cracked; and it was then deemed fortunate that the discovery had been made before the ponderous mass had been raised to its place in the tower. After further discussion and delays, a new bell was cast; but the casting was in this case entrusted to Messrs. Mears. The second bell is somewhat lighter than the first, but yields the same

note. It was raised to its place in October, 1858, and required mechanical appliances of a very complete kind; for the weight to be raised to a height of 200 feet, comprising bell, cradle, chains, and tackle, was not less than 25 tons, or 56,000 lbs. An inspection of the fragments of the first great bell, when broken up for recasting, showed that the metal exhibited much "speckiness," and was not in a state of aggregation suitable for the intended purpose. Altogether the cost of the great Westminster bell was not less than 3500*l*.

Mr. Denison, at the meeting of the Institution of British Architects above mentioned, gave a list of what he believed to be the largest bells known up to that time; it was as follows:—

	Weight. Tons.	Diam. Feet.	Thick. Ins.
Moscow (broken in 1737)	193	21	23
" (fell in 1855)	63		
Pekin	53		
Novogorod	31		
Vienna (1711)	17¾	9·8	
Sens	15	8·6	
Westminster (planned)	14	9·2	9
Erfurt (1497)	13¾	8·6	
Notre Dame	12¾	8·6	7½
Montreal (1847)	12¾	8·6	8¼
Cologne	11¾		
York (1845)	10¾	8·3	8
Bruges	10¼		
St. Peter's	8		
Oxford (1680)	7½	7·1	6½
Antwerp	7¼		
Exeter (1675)	5½	6·3	5
Lincoln (1834)	5½	6·8	6
St. Paul's (1709)	5¼	6·7	
Ghent	5		
Boulogne	5		
Old Lincoln (1610)	4½	6·3	
Westminster, 1st quarter bell	4½	6·1	6

Other examples, collected by other authorities, are the following:—Olmütz, 18 tons; Breslau, 11; Görlitz, 10¾; Mechlin, 9; Halberstadt, 7½; Dantzic, 6.

BELL COTE, BELL GABLE, or BELL TURRET, in religious edifices a small pierced turret, or open termination of the western gable, in which one or more bells are hung. The bell gable is found in small churches or chapels which have no towers, and is often of very picturesque and pleasing form. In some instances it is a good deal enriched, in others nearly plain. Bell gables rarely occur in English churches of the Norman period; but are numerous in those of the 12th, 13th, and 14th centuries. In the chapel of St. Nicholas, Glastonbury, occurs a flat bell gable, pierced for two bells, with buttresses at the angles; and at Shipton Olliffe church, Gloucestershire, is a very good one of the turret form, also for two bells; these two examples, both of which are of about the middle of the 13th century, are engraved in Parker's 'Glossary of Terms used in Gothic Architecture.' There is an octagonal bell-turret pierced for two bells, of very good form, but of much later date at Corston church, near Bath. When a similar bell-turret occurs at the apex of the eastern gable of the nave, or over the chancel arch, it was intended to contain the sanctus or mass bell, or the bell which is rung in Roman Catholic churches at the elevation of the host. [BELL.] Several of these turrets still remain, and a few with the bell in them, as at Long Compton, Warwickshire (Parker's 'Glossary'). Bell-turrets of this kind are not infrequently met with in French churches of the 13th and 14th centuries, as at Villons, Calvados (De Caumont; Viollet le Duc).

BELL-METAL. An alloy of copper and tin used for bells, cymbals, gongs, or other sonorous bodies of a similar nature. The proportions usually adopted vary slightly according to the size of the bell to be made; but they may be stated generally to be 80 parts of copper to 20 of tin, or even occasionally 77 parts of copper to 23 of tin. Bell-metal in its natural state, that is to say, in the state in which it leaves the furnace and has become cool, is brittle; if, however, it should subsequently be heated, and then suddenly cooled (by dipping it in water containing some salts in solution), instead of becoming harder, it will become very ductile and malleable. The sonority of a mass of bell-metal thus chilled will be increased by a slow process of annealing.

BELLADONINE. An alkaloid of uncertain composition said to be contained in the leaves and stems of the deadly nightshade.

BELLA'TRIX, the name of the smaller of the two bright upper stars in Orion. The three stars of the belt rather incline towards it; it is of the second magnitude, and is marked γ by Rayer, and 24 by Flamsteed. The name (warrior) is indicative of the supposed astrological properties of the star; the old Arabic name is Al Mirzam al Nâjid, *the valiant lion*. [ORION.]

BELLES LETTRES, a vague term used by the French, which has been adopted by other nations, to signify various branches of knowledge, which are the produce of the imagination and taste, rather than of serious study and reflection. We do not find that the limits of this description of knowledge have been clearly defined. Rhetoric, poetry, history, philology, are generally understood to come within the definition of belles lettres; but the mathematical and natural sciences, jurisprudence, metaphysics, ethics, and theology, the fine arts, and the

mechanical arts, are considered distinct from them. Antiquarian and classical researches are not always included among the belles lettres: the French Academy 'des Inscriptions et Belles Lettres,' seems by its very title to make a distinction between the two, as the first part of the title, 'Inscriptions,' refers to the investigation of ancient or oriental inscriptions, medals, &c. Belles lettres may be said to answer to the *literæ humaniores* of the Latin language, and to the English expression "polite literature."

BELLONA, one of the group of small planets revolving between Mars and Jupiter. [ASTEROID.]

BELLO'NA, the goddess of war among the Romans, corresponding in some measure with Enyo of the Greeks; but as was observed under ARTEMIS, the habit of regarding the names of Greek and Roman deities as convertible, is one from which much confusion has arisen in the study of ancient mythology. As was then explained, the names of a very large proportion of the Roman deities have grown out of the language itself. Bellona is properly a feminine adjective, which with the noun *dea* signifies the goddess of war (from *bellum*, war). And on the principle which runs through the Roman mythology, of dividing every object of fear or desire between deities of each sex, Bellona presided over war with Mars or Mavors. By Roman writers she is spoken of as the companion of Mars, also as his wife, or sister. She is supposed by some to have been originally a Sabine deity, and her worship to have been introduced by the Sabine settlers in Rome.

The temple of Bellona was founded, according to Pliny (xxxv. 3), in the year 259 of Rome, by Appius Claudius, the colleague of P. Servilius Priscus. Livy, however (x. 19), refers the foundation to Appius Claudius Cæcus, the colleague of L. Volumnius, in the year of Rome 456; and the latter is confirmed by an inscription in Gruter (389. 4). Both accounts will be substantially true, if the latter only rebuilt the temple. When any Roman family had once connected its name with a public work, those who afterwards bore the name had a pride in keeping up the connexion. The temple was situated in the ninth region, between the Carmental Gate and the Flaminian Circus, and consequently without the walls of Servius. It was on this account the place usually selected by the Roman senate and consuls for the reception of embassies from hostile powers, and also of their own generals, especially when these came to claim a triumph; for the *imperium*, or supreme military authority, was at once annulled by an entrance into the city, and with it all claim to a triumph. Near the temple was a column, over which a spear was hurled as a declaration of war against any foreign state. (Ovid, 'Fasti,' vi. 201.) This rite was introduced to supply the place of another. According to the original ceremony, a herald, or *fecial*, proceeded to the frontiers, and hurled a spear of defiance into the hostile territory; but as the limits of the empire were extended, this became impracticable.

The goddess was usually represented as wearing a helmet, and bearing a shield in one hand, in the other a firebrand, a spear, or a lash. Sometimes she was blowing a trumpet, or uttering a war-cry and rushing to the combat. Her image is seen on the coins of the Bruttii, or Brettii. (Montfaucon, 'Ant. Ex.' i. 125.)

The wildest extravagance marked her worship. Her priests (Bellonarii), like those of Cybele and Bacchus, affected insanity (Juvenal, iv. 123), whirling their heads round with fearful rapidity, and shrieking out words of pretended prophecy. On the 24th of March, which was appropriately called the day of blood (*dies sanguinis*), they exhibited their zeal by making incisions in their arms, and sprinkling all around with their blood. The more prudent among her followers, however, contrived to produce the appearance of wounds without any self-torture, a laxity which the Emperor Commodus corrected by a special precept that the devotees of the goddess should make actual incisions; but, besides the priests officially attached to the worship of the goddess, there were volunteers, who, impostors or enthusiasts, frequented her temple and exhibited the same symptoms of phrenzy. Such scenes indeed were to be seen in the temples of other deities, but more particularly in that of Bellona. The wretched creatures were called *fanatici* (from *fano*, a temple), which though a term of reproach or compassion among the educated, was a title of honour in their own estimation, and proudly engraved on public monuments. See an inscription given by Gruter, 313, 1, "To Q. Cæcilius Apollinaris, fanatic of the temple of Bellona," and another in 312, 7.

The worship of Bellona was not unlike that of the goddess Ma, in the sacred cities of Cappadocia and Pontus called by the common name of Comana; and hence the Roman writers often use the title of Bellona when speaking of the Cappadocian goddess. Strabo in the same way calls her Enyo.

The earliest orthography of the name of the Roman goddess was Duellona, agreeing with *duellum*, the older form of *bellum*. [See article B, for the interchange of *du* before a vowel with *b*.]

BELLOWS. This term is applied not only to the common instrument in use, but also to any machine which serves to force a current of air against a fire. In general, however, it is more customary to apply the term blowing-machine to the larger species of apparatus. The principle of all these different adaptations of parts is the same, and is very similar to that of a forcing-pump. By one motion a vacuum would be made, if it were not for a valve which opens towards the incipient vacuum, and admits the air: by a contrary motion the air

just admitted is expelled, not by the valve which is now closed, but by any other orifice.

When a furnace is to be supplied with a perpetual blast of air, it may have two separate bellows, worked by the same machinery, in such a way that one is discharging air while the other is receiving a new supply. The inconvenience of this construction is, that the blast, though perpetual, is not of uniform strength. The blast-furnaces of some of the great Welsh iron-works are worked by one huge air-pump, which condenses the air in spherical reservoirs, out of which the blast-pipes lead to the furnaces. In cases where a uniform and gentle blast is required, as in the organ, the air is condensed into a reservoir called the wind-chest, which supplies the pipes. [ORGAN.] A patent was obtained some years ago for a construction by which a perpetual and uniform blast is produced, applicable to the domestic bellows. It consists in a vane wheel, which is enclosed in a vessel communicating with a tube, the vessel and tube being, in their longitudinal section, in form like that of a retort. A supply of air is obtained by holes in the side of the vessel, so that, on turning the vane by an exterior apparatus, the air is driven through the tube, and the blast thus created is permanently supplied by the lateral holes. These instruments are more effective than the bellows in common use; but they have effected little towards superseding the old familiar bellows.

The oldest representation of bellows is in the Egyptian paintings copied in the work of Rosellini. There are two pairs of bellows, one on each side of the fire, with which they are connected by long tubes of wood or cane, terminating in pointed metal snouts. A string is attached to each bellows, and the blower takes one string in his right hand and the other in his left. He presses with one foot on the bellows that is filled with air, at the same time raising his other foot from that which is just exhausted, and also pulling upwards with the string that is attached to it.

The largest kinds of bellows, with other contrivances for producing a powerful blast of air, will be more conveniently described under BLOWING MACHINE.

BELTEIN, or BELTANE, the name of a kind of festival, formerly observed in Ireland and Scotland, in most places on the 1st of May. In some parts of the west of Scotland it is observed on St. Peter's day, June 29. In Ireland we find two belteins, one on the 1st of May, the other on the 21st of June. To the beltein, also, in all probability, the fires which were formerly lighted in many parts of England on Midsummer Eve, are to be referred.

Beltein signifies the fire of Baal, the worship of whom is supposed to have existed in England, Scotland, and Ireland in the remotest period of druidical superstition. The Phœnician Baal probably denoted the Sun [BAAL], as Ashtaroth did the Moon. Beltein was therefore the fire lighted in honour of the Sun whose return and visible influence upon the productions of the earth was thus celebrated. *La na Beal tina*, and *neen na Beal tina*, in the Irish language, are the day and eve of Beal's fire. ('Fairy Legends and Traditions of the South of Ireland,' and MacCurtin's 'English-Irish Dict.' 4to, Par. 1732.)

The following account of the beltein is given in 'Focalóir Gaoidhíle-Sax-Bhéaria,' or an Irish-English Dictionary (by O'Brien), printed at Paris, 4to, 1768:—"Beáltine, or béil-tine, ignis Beli Dei Asiatici: that is, *tine-Bel*, May-day, so called from large fires which the Druids were used to light on the summits of the highest hills, into which they drove four-footed beasts, using at the same time certain ceremonies to expiate the sins of the people. This pagan ceremony of lighting these fires in honour of the Asiatic god Belus, gave its name to the entire month of May, which is to this day called *mi na Beal-tine* in the Irish language. Dr. Keating, speaking of this fire of Beal says, that the cattle were driven through it and not sacrificed, and that the chief design of it was to keep off all contagious disorders from them for that year; and he also says, that all the inhabitants of Ireland quenched their fires on that day, and kindled them again out of some part of that fire. The above opinion about the cattle is confirmed by the following words of an old glossary, copied by Mr. Edward Lhuyd: *Da tene soimech do gúitis na drafthe continct laib moraib foruib: agus do berdis na ceatra entra or teomanduib cecha bliadna*: the main sense of which is, that the Druids lighted two solemn fires every year, and drove all four-footed beasts through them in order to preserve them from all contagious distempers through the current year." Brand in his 'Popular Antiquities,' gives an account of a number of superstitious observances and ceremonies connected with this custom.

BELTS, JUPITER'S. [JUPITER.]

BELUS (בֵּל or בֵּלַי, βήλος) was the name of the chief deity of the Babylonians and Assyrians, the same as Baal, the chief deity of the Semitic races [BAAL]. The Chaldee *Bel* (בֵּל), as well as the Hebrew *Baal* (בֵּלַי), means *Lord*. The Greeks were apt to substitute Zeus for Belus, and the Romans Jupiter. The planet Jupiter was also worshipped under the name of Baal by the old Arabians as the chief star of happiness. The temple of Belus at Babylon was plundered and much damaged by Xerxes. Alexander gave orders for its restoration; but the priests being slack in executing the work, he intended to employ the whole army in rebuilding the temple. According to Herodotus (i. 7), Belus was the father of Ninus.

(See Isai. xlv. 1; Jer. l. 2, li. 44; Baruch vi. 40; Herod. i. 178,

181-183; Diod. Sic. ii. 8, 10; Paus. i. 16, 3, viii. 33, 1; Plin. *Hist. Nat.* vi. 30, xxxviii. 55, 58; Arriani, *Anab.* iii. 16, vii. 16, 17; Cic. *Nat. Deor.* iii. 16; Norberg, *Onomast.* p. 28; Gesenius, *Jes.* vol. ii. pp. 286, 337, 358; Winer's *Realwörterbuch*, under Bel; Jahn, *Hebrew Antiquities*, § 407.)

BELVEDE'RE, in Architecture, is a small building constructed at the top of a house or palace, and open to the air, at least on one side, and often on all. The term is an Italian compound, signifying "a fine view;" and in Italy it is constructed expressly for that purpose, combined with the object of enjoying the cool evening breeze, which blows fresher on the house-top than in the confined streets. Many houses in Rome have belvederes, for the most part of a simple form. The most celebrated construction of this kind at Rome, which is in the Vatican, was built by Bramante in that part called the court of the

[View of the Belvedere of the Vatican, from a print in the British Museum.]

Belvedere. The form of this building is semicircular, and it stands over an enormous niche, a remarkable feature in the façade, of which the belvedere makes a part. From this belvedere the view is one of the finest that can be imagined, extending over the whole city of Rome and the Campagna, bounded by the distant Apennines, the tops of which are covered with snow for a large part of the year. Belvederes are not uncommon in France; but the term is applied rather to a summer-house in a park or garden, than to the constructions on the tops of houses, although small edifices, similar to those in Italy, are sometimes constructed on the tops of buildings for the purpose of commanding a fine view. Were buildings constructed in this country with a more thoughtful adaptation to their various purposes, a belvedere, suited to the particular locality, and not a mere unadapted copy of one of those of Italy, might often be made a very pleasing addition to an English mansion or villa residence. There is a small building in Windsor Great Park which is called a Belvedere.

It is not improbable that the wooden trellice-work, so common in the painted representations of buildings at Pompeii, was a construction similar in its purpose to the belvedere of the modern Italians. (*Plans and Elevations, in MSS. of the Vatican*, 3 vols. fol., and a *View of the Vatican in the King's Library*, *Brit. Mus.*; Gell's, and Mazois' *Pompeii*, plates.)

BEMA (βῆμα), was the pulpit, pedestal, or platform from which speakers addressed the public assemblies of the citizens of ancient Greece. The stone bema of the Pnyx at Athens still remains tolerably perfect, (except that the summit is broken,) with the seats from which it rises, and the steps by which it was ascended: its present height is about ten feet. (Wordsworth, 'Greece,' pp. 214, 215, ed. 1859; Murray's 'Handbook of Greece,' p. 186.)

The raised platform which formed the tribunal of the judge in the ancient Roman basilicas [**BASILICA**] was known as the bema, and hence when basilicas were adapted or imitated for Christian churches, the bishop's seat, in which he sat as well to adjudicate as to assist in the religious worship, was designated the bema. The term bema afterwards came to be applied to the entire sanctuary or holiest place of the basilica; the elevated seat of the bishop being placed at its farthest end, in the centre of the circle. The sanctuary of Greek churches is at the present day called the bema, but it is now always separated from the apsis by a solid wooden screen, which reaches to the ceiling.

BEN (בֶּן, constructed בֶּן־ or בְּן־, son) is the first syllable in many Hebrew names, which may be compared with our forms of names like Morrison, Johnson, Robertson, &c.: for instance, בֶּן־הָדָד, *Benhadad*, is the son or the worshipper of Hadad, or Adod, the chief idol of the Syrians. בֶּן־אֲוִי, *Benoni*, is son of my pain: בֶּן־יִמִּין, *Benjamin*, is son of the right (hand), that is, son of happiness. These examples show that not only literal sonship but also metaphysical relation is expressed by Ben. The construct state or regimen of a Semitic noun is that

shortening by which is expressed that it governs a following genitive as in the examples given.

BEN, OIL OF. An oil expressed from the fruit of the *Guilandina moringa*. It is a thick, slightly yellow fluid at 60° Fahr., and solid at lower temperatures. It is inodorous, and possesses a sweet taste. It does not readily become rancid, and is consequently used as a vehicle in perfumery. This oil has been examined by several chemists, but their results are somewhat discordant; it seems, however, to contain margaric and benic acids; and Walter states also, that stearic acid, and moringic acid (C₃₀H₂₈O₄) are amongst its constituents.

BENCH. [BANK.]

BENCHER. [INNS OF COURT.]

BENEDICTINE ORDER. The exact year when the monks who followed the rule of St. Benedict were first established as an Order is unknown. Although monks had been introduced from the East at least two centuries before the time of St. Benedict of Nursia, he may be considered, from the wide extension of the order, with its various branches, the great influence it acquired, and the real benefits it bestowed on society, to have been the real founder of monachism in Europe. The essence of the rule was that they were to live in a monastery subject to an abbot, to whom they owed implicit obedience; to observe silence and avoid laughter; to have no separate property; to submit to the very spare diet prescribed by rule; hospitality to be exercised towards strangers; mills, gardens, ovens, &c., to be provided, if possible, on the cloistral premises, the monks to work, and the workmen in the house to labour for the common profit. This last regulation gave birth to a great number of choice specimens of calligraphy and illumination; and Germany acknowledges the first important steps towards the clearing of their forests and improvements in agriculture and gardening, to the instruction and example of the Benedictine monks. The 'Histoire des Ordres Monastiques,' tom. v. 4to, Paris, 1718, upon Mabillon's authority, places the date of the monastery of Piombargle, near Monte Cassino, at least as early as the year 532, anterior to St. Benedict's death. The progress which this order made in the west, in a short time, was rapid. In France its interests were promoted by St. Maur, or Maurus, in Sicily by St. Placide, in Italy by St. Gregory the Great, and in Frisia, at a later period, by St. Wilbrod. The reciprocal protection afforded to the interests of the papal see by the Benedictine order, and to the interests of the Benedictine order, by the Roman pontiffs, sufficiently account for the order's advancement. There were nuns of this order as well as monks; but the time and original institution of the Benedictine nuns is quite uncertain; a tradition assigns it to St. Benedict himself, but the first historical mention of Benedictine nuns occurs in the 7th century.

The Benedictine order is said by many (see 'Monast. Angl.' vol. i.; Reynier, 'Apostol.' tr. i.; Stevens, vol. i.; and Mosheim, cent. vi. part ii. chap. ii.) to have been brought into England by St. Augustine and his brethren, A.D. 596, and to have continued from thence to the Dissolution under several improvements; but others (as Marsham in his 'Propulaion' prefixed to the 'Monasticon'; Patrick in his Additions to Gunton's 'History of Peterborough'; Hickes, 'Dissert. Epistolaris,' &c.) consider that the Benedictine rule was but little known in England till King Edgar's time, and never perfectly observed till after the Conquest. In the 'Decem Scriptores,' col. 2232, it is said that St. Wilfrid brought it into England A.D. 666, and in the 'Quindecim Scriptores,' and by Patrick in his Additions to Gunton, p. 247, with greater probability, that he improved the English church by it. It is expressly mentioned in King Kenred's charter ('Mon. Angl.' tom. i.) to the monks of Evesham, A.D. 709, and in the bull of pope Constantine, granted in the same year to that monastery. (See 'Mon. Angl.' ut supr.; Wilkins, 'Concil.' vol. i.; Spelm. vol. i.) But Bede, who has given us a very accurate account of the state of religion in this island till A.D. 731, has nothing of it; nor is there any mention of it in the first regulation of the monks in England by Archbishop Cuthbert in the great synod at Cloveshoe. (Wilkins, 'Concil.' vol. i.; Spelm. vol. i. A.D. 747.) If Wilfrid really advanced this rule, it was not over all England, but in Kent only. (See Patrick's Additions to Gunton's 'Peterborough.') And if the charter of King Kenred and the bull of pope Constantine be genuine (for all the ancient grants produced by the monks are not so), this rule, which is there prescribed to the monks of Evesham, is said in the bull to "have been at that time but little used in those parts." So that, instead of the Saxon monks being all Benedictines, there were probably but few such till the restoration of monasteries under King Edgar, when St. Dunstan and St. Oswald (who had been a Benedictine monk at Fleury in France) not only favoured the monks against the secular clergy, but so much advanced the Benedictines that William of Malmesbury ('De Gestis Pontif.' l. iii.) says this order took its rise in England from St. Oswald. The Ely historian (whose work is printed in Wharton's 'Anglia Sacra,' vol. i.) says, that King Edgar gave Ethelwold the manor of Suthborne, now Sudborn, in Suffolk, to translate the rule of St. Benedict into English, which seems to confirm the opinion of its being then but little known.

All our cathedral priories were of this order, except Carlisle, and most of the richest abbeys in England, Reynier ('Apostolat.' vol. i.) says, that the revenues of the Benedictines were almost equal to those of all the other orders. Tanner ('Notit. Monast.' lii.) enumerates one

hundred and thirteen abbeys, priories, and cells of this order in England, the sum of whose revenues, at the time of the Dissolution, amounted to 57,892*l.* 1*s.* 11*d.*, besides seventy-three houses of Benedictine nuns, whose revenues amounted to 7985*l.* 12*s.* 1*d.*, making a total of 65,877*l.* 14*s.*

The Benedictines, says Tanner, were much against all new orders of religions. By the second Lateran council they were obliged to hold triennial chapters, which those of this nation generally held at Northampton. (See Widmore, 'Hist. Westm. Ab.' pp. 79, 82.)

Fosbrooke, in his 'British Monachism,' has given an abstract of the Benedictine rule, chiefly from the 'Sanctorum Patrum Regulæ Monasticæ,' 12mo, Louv. 1571. It evidently received enlargements at different times, the whole of which were consolidated in the concord of rules promulgated by Dunstan in the reign of Edgar. (See the 'Concordia Regularum S. Dunstani Cantuariensis Archiepiscopi,' printed by Reynier in his 'Apostolatus Benedictinorum in Anglia,' Append. P. iii., and republished in the first volume of Dugdale's 'Monasticon.') This concord of rules regulated the practice of the English monks till the year 1077. The Cluniacs, Cistercians, Grandmontines, Premonstratensians, and Carthusians, were, in reality, branches only of the Benedictine order, living under the rule of St. Benedict, but observing a different discipline.

As the order increased in wealth and number corruptions gradually crept in, and various reformers arose at different times, who endeavoured to remedy these evils. Benedict of Aniano, in 817, formed new rules for the whole order; but other reformers, as St. Bernard, formed new orders under the names mentioned above. Notwithstanding all the attempts at reform, the old vices recurred with the acquisition of wealth, and immediately before the Reformation, the order counted between 15,000 and 16,000 monasteries; these were reduced almost immediately to between 5000 and 6000. At the beginning of the present century a large number of them were suppressed in France, Germany, and other continental countries, the estates distributed in various ways, the monks dispersed, either with a pension, to be employed in some court capacity, or to mix with the world as simple laics; and their excellent libraries, in most cases, taken possession of by the government. There has been since that time, a partial revival, but the number of houses now does not at most exceed 500.

The habit of the Benedictine monks was a black loose coat, or a gown of stuff reaching down to their heels, with a cowl or hood of the same, and a scapulary; and under that another habit, white, as large as the former, made of flannel; with boots on their legs. From the colour of their outward habit, the Benedictines were generally called Black Monks. (See Tann. 'Notit. Monast.' pref.; and Fosbrooke, 'Brit. Monach.') Stevens, in his 'Continuation of the Monasticon,' vol. i., says, the form of the habit of these monks was at first left to the discretion of the abbots, and that St. Benedict did not determine the colour of it.

The habit of the Benedictine nuns consisted of a black robe, with a scapulary of the same, and under that robe a tunic of white or undyed wool. When they went to the choir, they had, over all, a black cowl, like that of the monks. (Fosbrooke's 'British Monachism,' 3rd edit. 1844.)

BENEDICTION, the act of invoking the favour of God, prosperity, long life, and other blessings upon individuals. The word is derived from the Latin, *benedicere*, which originally meant "to speak well," or "to praise or commend," and was afterwards employed for "to wish well." (See Ducange's 'Glossarium.') The ceremony of blessing is of a very remote antiquity. We find in the Scriptures that the patriarchs before they died, solemnly bestowed their blessing on their sons. Isaac giving by mistake to his younger son Jacob the blessing which he intended for his elder son Esau (Genesis xxvii.), is an interesting instance of this custom. In Numbers vii. 23-26, the words are specified in which the high priest was to bless the people of Israel. Aaron blessed the people, "lifting his hand towards them." (Leviticus ix.) Christ after his resurrection, and before parting from his disciples at Bethany, "lifted up his hands and blessed them." (St. Luke xxiv. 50.) In the early church, the bishop gave his blessing to the people with his hands extended towards them. In the Roman Catholic church it is the custom for the bishop to lift up his right hand towards the people with the fingers extended, and with it to describe the sign of the cross, in commemoration of the Redemption. The benediction, "*Benedictio super populum*," is also given by the bishop from the altar in the mass service, with the words "*Benedicat vos Omnipotens Deus*." The priests also give the benediction, but with some difference in the form and words, and they can only give it at mass, or while administering the sacrament, or in other solemn ceremonies; but the bishop has the power of giving it any where or upon any occasion he may think fit. In the Roman Pontificale are found the various forms of benediction. One of the most impressive instances of this ceremony is that of the pope in full pontificals, attended by the cardinals and prelates, giving his benediction "*Urbi et Orbi*" on Easter Sunday after mass, from the great gallery in the front of St. Peter's church, while the vast area beneath is filled with kneeling spectators.

The benediction forms an essential part of many ceremonies of the Roman Catholic church, such as the coronation of kings and queens, the confirmation of abbots and abbesses, the consecration of churches, altars, and sacramental vases. These are all performed by the bishop,

and are accompanied by different ceremonies, such as anointing, imposing of hands upon the head of the person consecrated, &c. The benediction of church utensils, of bells, of sacerdotal garments, of churchyards, &c., may be performed by priests. The nuptial benediction, which is an essential part of the marriage ceremony, is given by the parish clergyman. The priests also in some instances give benediction to houses, fields, horses, cattle, &c., by sprinkling them with holy water. This custom of blessing those things which are for the use or support of man is of great antiquity. It is found in St. Gregory's 'Sacramentale,' and, before him, in that of Pope Gelasius I., who lived in the 5th century. The "*benedictio mensæ et ciborum*," was a general practice among all Christians before sitting down to dinner: the English custom of saying grace is a continuation of it.

There is also in Roman Catholic churches a service which is commonly called, in Italy at least, "the Benediction," and is performed on particular days, and generally in the evening; after certain prayers being said or sung, the consecrated host is raised up by the officiating priest, who describes with it the sign of the cross towards the congregation.

The benedictorium is the vase containing the holy water, which is placed at the entrance of Roman Catholic churches for the use of the people, who dip their fingers into it and cross themselves as they go in and out. The water is blessed by the priest, and is mixed with salt.

The pope begins his bulls and other communications addressed to Roman Catholic individuals with the greeting "*Salutem et apostolicam benedictionem*."

In the Liturgy of the Church of England there are but two benedictions: one, which is as much a supplication by all the congregation as a blessing from the priest, at the end of the prayers; the other is introduced on administering the sacrament, and pronounced at the end of the sermon.

BENEFICE, from the Latin *beneficium*, a term applied by the canon law to a provision for an ecclesiastical person. In its most comprehensive sense it includes the temporalities as well of archbishops, bishops, deans and chapters, abbots and priors, as of parsons, vicars, monks, and other inferior spiritual persons. But a distinction is made between benefices attached to communities under the monastic rule (sub regulâ), which are called *regular* benefices, and those the possessors of which live in the world (in sæculo), which are thence called *secular* benefices. The writers on the canon law distinguish, moreover, between simple or sinecure benefices, which do not require residence, and to which no spiritual duty is attached but that of reading prayers and singing (as chaplainries, canonries, and chantries), and *sacerdotal* benefices, which are attended with cure of souls.

Lord Coke says, "*Beneficium* is a large word, and is taken for any ecclesiastical promotion whatsoever." (2 'Inst.' 29.) But in modern English law treatises the term is generally confined to the temporalities of parsons, vicars, and perpetual curates, which in popular language are called livings; the legal possessor of a benefice attended with cure of souls being generally called the incumbent.

The history of the origin of benefices is involved in great obscurity. The property of the Christian Church appears, for some centuries after the apostolic ages, to have been strictly enjoyed in common. It was the duty of the officers called deacons (whose first appointment is mentioned in Acts, chap. vi.) to receive the rents of the real estates, or *patrimonies* as they are called, of every church. Of these, as well as of the voluntary gifts in the shape of alms and oblations, a sufficient portion was set apart, under the superintendence of the bishop, for the maintenance of the bishop and clergy of the diocese; another portion was appropriated to the expenses of public worship (in which were included the charge for the repairs of the church), and the remainder was bestowed upon the poor. This division was expressly inculcated by a canon of Gelasius, bishop of Rome, A.D. 470; and after the payment of tithes had become universal in the west of Europe, as a means of support to the clergy, it was enacted by one of the capitularies of Charlemagne, that they should be distributed according to this division. When the bishoprics came to be endowed with estates, the bishops, to encourage the foundation of churches, and to establish a provision for the resident clergy, gave up their portion of the tithes, and were afterwards by the canons forbidden to demand it, if they could live without it. Although the revenues of the Church were thus divided, the fund from which they were derived remained for a long time entirely under the same administration as before. But by degrees every minister, instead of carrying the offerings made in his own church to the bishop for the purpose of division, began to retain them for his own use. The lands also were apportioned in severalty among the resident clergy of each diocese. These changes were not, however, made in all places or all at one time, or by any public edict, but by insensible degrees, as all other customs are introduced. "Some writers have attributed the origin of parochial divisions to a period as early as the 4th century: and it is not improbable that this change took place in some parts of the Eastern Empire, either in that or the succeeding age. Some of the constitutions of Justinian seem to imply that in his time (the beginning of the 6th century) the system of ecclesiastical property, as it existed in the East, was very similar to that which has prevailed in Catholic countries in modern times." For the churches, monasteries, and other pious foundations possessed landed and other property (slaves among the rest), which, by the constitutions of Justinian, they are restrained from

alienating as they had been in the habit of doing to the detriment of their successors. (Father Paul's 'Treatise on Ecclesiastical Benefices.')

The general obscurity that hangs over the history of the middle ages prevents us from ascertaining, with precision, at what period the changes we have alluded to were introduced into the west of Europe. This, however, seems clear, that after the feudal system had acquired a firm footing in the west of Europe, during the 9th and 10th centuries, its principles were soon applied to ecclesiastical as well as lay property. Hence, as the estates distributed in fief by the sovereigns of France and Germany among their favoured nobles, were originally termed *beneficia* [BENEFICIUM], this name was conferred, by a kind of doubtful analogy, upon the temporal possessions of the Church. Thus, the bishoprics were supposed to be held by the bounty of the sovereigns (who having by degrees obtained, had now usurped the right originally vested in the clergy and people, of filling them up when vacant), while the temporalities of the inferior ecclesiastical offices were held of the bishops, in whose patronage and disposal they for the most part then were. The manner of investiture of benefices in those early times was probably the same as that of lay property, by the delivery of actual possession, or of some symbols of possession, as the ring and crozier, which were the symbols of investiture appropriated to bishoprics.

Benefices being thus endowed, and recognised as a species of private property, their number gradually multiplied during the ages succeeding that of Charlemagne. In England especially several causes contributed to the rise of parochial churches. "Sometimes (Dr. Burn, 'Eccles. Law,' tit. *Appropriation*) the itinerant preachers found encouragement to settle amongst a liberal people, and by their assistance to raise up a church and a little adjoining manse. Sometimes the kings, in their country villas and seats of pleasure or retirement, ordered a place of worship for their court and retinue, which was the original of royal free chapels. Very often, the bishops, commiserating the ignorance of the country people, built churches as the only way of planting or keeping up Christianity among them. But the more ordinary method of augmenting the number of churches depended on the piety of the greater lords; who, having large fees and territories in the country, founded churches for the service of their families and tenants within their domains. It was this that gave a primary title to the patronage of laymen, and made the bounds of a parish, in many cases, commensurate to those of a manor: and it was this distinct property of lords and tenants that by degrees allotted new parochial bounds, by the adding of new auxiliary churches." [ADVOWSON.]

It appears, however, that if there were any new fee erected within a lordship, or there were any people within the precinct not dependent on the patron, they were at liberty to choose any neighbouring church or religious house, and to pay their tithes and make their offerings wherever they received the benefits of religion. This by degrees gave rise to the arbitrary appropriation of tithes, which, in spite of positive enactment, continued to prevail till the end of the 12th century, when Innocent III. by a decretal epistle to the archbishop of Canterbury, enjoined the payment of tithes to the ministers of the respective parishes where every man dwelt. This injunction has been complied with ever since, so that it is now a universal rule of law in England, that tithes are due of common right to the parson of the parish. [TITHES.]

The 12th century was also the era of an important change in the manner of investiture of ecclesiastical benefices in England. Up to this time the simple donation of the patron was sufficient to confer a legal title to a benefice, provided the person to whom it was given was in holy orders, for otherwise he must be first presented to the bishop, who had power to reject him in case of unfitness; but the popes, who had in the 11th and 12th centuries successfully contended against every other species of ecclesiastical investiture being exercised by laymen, now procured that the presentation of the patron should not be of itself sufficient to confer an ecclesiastical benefice, even though qualified by the discretionary power of rejection (in case the benefice was given to a layman), which was already vested in the bishop. This was the origin of the ceremonies of *institution*, which is the mode of investiture of the spiritualities; and *induction*, which is the mode of investiture of the temporalities of a benefice. Where the bishop was the patron of the benefice, the two forms of *presentation* and *institution* were united in that of *collation*. But this is not the place to treat of the origin and nature of ecclesiastical patronage in England as a subject of property, the rules of law which apply to it as such, the limitations within which and the forms according to which it must be exercised, or the mode by which it may be vindicated. These, and the respective rights of the bishop, the archbishop, and the crown, in the case of lapse, are treated of under more appropriate heads. [ADVOWSON; QUARE IMPEDIT.]

Although the popes, in denying to laymen the right of ecclesiastical investiture, had still left them in possession of the substantial part of the patronages of benefices, even this privilege was for some centuries not only very much questioned, but in many instances entirely wrested from them by papal encroachment.

The first attacks by the popes upon the rights of private patrons (which took place towards the latter end of the 12th century) assumed the form of letters of request called 'mandates' or 'expectatives,' praying that benefices might be conferred on particular individuals. What was first asked as a favour was soon claimed as a right, and rules

were laid down as to grants and revocations of expectatives. The popes next proceeded to claim the patronage of all benefices *vacantia in curia*, that is, which fell vacant by the incumbents dying at the court of Rome. The number of these, through the management of that court, which contrived on various pretences to draw ecclesiastics of all ranks to Rome from different parts of Europe, became by degrees very considerable. But Clement V. in the beginning of the 14th century went beyond all his predecessors, by laying it down broadly as a maxim, that the full and free disposition of all ecclesiastical benefices belonged to the pope. (Clementines, lib. ii. tit. 5, c. 1.) It followed as a consequence from this principle, that the pope could make reverſionary grants or *provisions*, as they were called, during the lives of the incumbents; and that he could reserve such benefices as he thought fit for his own peculiar patronage. At the same time, dispensations from the canons against non-residence and pluralities, and permissions to hold benefices *in commendam* were freely granted, so that by these and similar means, in some instances fifty or sixty preferments were held by the same person at once. The evils of this system were felt all over Europe. The best benefices were everywhere filled with Italian priests, ignorant alike of the language and habits of the people to whose spiritual wants they were bound to minister. England in particular suffered so much from papal encroachments during the reign of Henry III., that the English deputies at the Council of Lyon (A.D. 1245) complained to the pope that the foreign clergy drew annually from England upwards of 70,000 marks. This remonstrance produced no effect, but the system at length became so intolerable, that a determined plan of opposition to it was gradually formed in the principal nations of western Europe. In this opposition our own ancestors took the lead, and their efforts were in the end completely successful. The parliament, assembled at Carlisle 35 Edw. I., wrote a strong remonstrance to Clement V. against the papal encroachments on the rights of patronage, and the numerous extortions of the court of Rome. This appears to have produced no effect, but it may be cited as a proof of the spirit of the times. The government of Edward II. was too feeble to act; but Edward III. was a prince of very different character. After complaining ineffectually to Clement VI. of the abuse of papal reservations, he procured the famous Statute of Provisors (25 Ed. III. stat. 6); which provided that all elections and collations should be free according to law, and that in case any provision, collation, or reservation should be made by the court of Rome of any archbishopric, bishopric, dignity, or other benefice, the king should for that turn have the collation of such archbishopric or other dignities elective, &c.

This statute was fortified by several others in this and the succeeding reigns, 27 Ed. III. stat. 1, c. 1; 38 Ed. III. stat. 1, c. 4; 3 Rich. II. c. 3; 7 Rich. II. c. 12 (which enacts that no alien shall be capable of being presented to any ecclesiastical preferment); 12 Rich. II. c. 15; 13 Rich. II. stat. 2, cc. 2 & 3; 16 Rich. II. c. 5; 2 Hen. IV. c. 3; 7 Hen. IV. c. 8; 3 Hen. V. c. 4. These statutes, which inflict very severe penalties on persons endeavouring to enforce the authority of papal bulls and provisions in England, are sometimes called, from the initial words of the writ issued in execution of the process under them, the statutes of *præmunire*; and the offence of maintaining the papal power is from this origin usually designated by that term. [PRÆMUNIRE.] The statutes against papal provisions (though not very strictly enforced) remained unrepealed, in spite of the frequent attempts of the popes and their adherents to obtain their abrogation.

The rights of ecclesiastical patronage having been thus solemnly vindicated by parliament, have, in their fundamental principles, remained unaltered to the present time. The ceremonies of *presentation* and *institution* in the case of lay patrons, and of *collation* where the bishop is patron, are still necessary to give a title to all benefices with cure of souls, except those which are technically called perpetual curacies and donatives; and the title so given is incomplete without corporal *induction* into possession of the temporalities of the benefices. There are, also, certain acts enjoined either by the canon law or statute, the non-performance of which will subject the incumbent to deprivation of the benefice into which he has been lawfully inducted.

There is no difference between institution and collation as to the action itself, but they differ somewhat in their respective consequences. Thus, by institution, the church is said to be full against all persons but the crown, and if it has been full for the space of six months, this is a sufficient answer to any action by private persons, or even by the sovereign, where he claims as a private patron and not by royal prerogative, as in case of lapse, or otherwise. But, by collation, the church is not full, so as to render a plea to that effect available in the temporal courts, except against the collator. Every clerk before institution or collation is required by the canon law to take the oath against simony, and the oath of canonical obedience to the bishop, and to declare by subscription his assent to the doctrine of the royal supremacy, to the Book of Common Prayer, and the Thirty-nine Articles. The subscription to the Thirty-nine Articles is also imposed by statute 13 Eliz. c. 12, upon all persons to be admitted to any benefice with cure of souls. Moreover, the statute 1 Eliz. c. 1, and 1 Will. & Mary, c. 8, sec. 5, require that every person collated or promoted to any ecclesiastical benefice shall, before he takes upon himself to supply or occupy the same, take the oaths of allegiance and supremacy, for which, however, one form of oath has now been substituted. [ALLEGIANCE.] The statute 13 & 14 Car. II. c. 4 (the Act of Uniformity),

requires every parson and vicar before his admission to be incumbent, to subscribe a declaration of conformity to the Liturgy of the Church of England as by law established.

The acts of institution or collation so far confer a right to the temporalities of the benefice, that the clerk may enter upon the glebe land and take the tithes, but he cannot sue for them or grant them until induction. By induction the church becomes full, even against the crown, and the clerk is seized of the temporalities of the benefice, and invested with the full rights and privileges of parson; but by the Act of Uniformity he must, within two months after he is in actual possession of his benefice, upon some Sunday, openly before his congregation, read the morning and evening prayers, and declare his assent to the Book of Common Prayer, on pain, in case of neglect or refusal, of being *ipso facto* deprived of his benefice. The same statute obliges him, on pain of deprivation, to read publicly, within three months after his subscription to the declaration of conformity to the Liturgy, the bishop's certificate of his having made such subscription, together with the declaration itself. The statute 23 Geo. III. c. 28, however, makes an exception where the incumbent is prevented by some lawful impediment, to be allowed and approved of by the ordinary of the place. The same penalty of deprivation is imposed by 13 Eliz. c. 12, in case of an incumbent failing, within two months after induction, to read publicly in the church the Thirty-nine Articles, and to declare his assent to them. The 23 Geo. III. c. 28, provides, that, in case of sickness or other lawful impediment, it shall be deemed a sufficient compliance with the statute of Elizabeth if the incumbent reads the Articles, and declares his assent to them at the same time that he declares his assent to the Book of Common Prayer. The parson must, within six months after his admission to the benefice, take the oaths of allegiance in one of the courts at Westminster, or at the general quarter sessions of the peace, on pain of being incapacitated to hold the benefice, and of incurring certain other disabilities therein specified. Such are the means by which a clerk's legal title as parson, rector, or vicar is acquired, asserted, and completed.

Every parson or rector of a parish with cure of souls, and where the parsonage is appropriated, every vicar or perpetual curate, though in his natural capacity an individual, is in contemplation of law a body corporate, with perpetuity of succession. The rector or parson is seized of the freehold of the parsonage house and glebe lands, as well as the tithes of the parish, except where a special exemption from the payment of tithes exists by prescription or otherwise; but owing to the practice of appropriation, which formerly prevailed to a great extent in England, and has been attended with very remarkable consequences, these are frequently vested in laymen, who have vicars or curates under them to perform the spiritual duties. [ADVOWSON.] This custom was not confined to spiritual corporations aggregate, but deans and other officers in cathedrals, and in some places even parish priests, procured the privilege of appointing a vicar to perform the spiritual duties of the church, while its revenues were appropriated to themselves and their successors. Hence it happens that in some places a rector and vicar are instituted to the same church; in which case the rector is excused from duty, and the rectory is called a sinecure benefice, as being *sine cura animarum*. In order to effectuate an appropriation it was necessary that the patron should obtain the consent of the crown and of the bishop, as each of these had an interest in the patronage of the church in case of lapse, which, as a corporation never dies, could not take place after the appropriation. Upon the making an appropriation, an annual pension was formerly reserved to the bishop and his successors, called an indemnity, and payable by the body to whom the appropriation was made. In an ancient deed of appropriation preserved at Canterbury, the ground of the reservation is expressed to be for a recompense of the profits which the bishop would otherwise have received during the vacancy of the benefice.

After the appropriation the appropriators and their successors became perpetual parsons of the church; but if the corporation were dissolved, the perpetuity of persons being gone, the appropriation ceased, and the church recovered its rights.

This principle would have come into extensive operation at the time of the dissolution of the monasteries in England, if the legislature had not expressly provided against it. By the statutes 27 Henry VIII. c. 28, and 31 Henry VIII. c. 13, the possessions of these religious houses, and by a subsequent statute, 32 Henry VIII. c. 24, those of the Knights of St. John of Jerusalem, were all vested in the crown. In each of these statutes, parsonages and tithes are expressly included, and the first two confirm the royal grants made or hereafter to be made of this property. Tithes are also included in two subsequent statutes, 37 Henry VIII. c. 4 and 1 Edward VI. c. 14, by which the possessions of chantries and religious fraternities are given to the crown. The last of these statutes empowers the commissioners, therein referred to, to ordain and sufficiently endow vicars in perpetuity in parish churches annexed to the religious fraternities whose possessions were confiscated by that act; and also to endow in perpetuity a schoolmaster or preacher in such places where the religious fraternities or incumbents of chantries were bound by the original foundation to keep a schoolmaster or priest. The property acquired by the crown from the above-mentioned sources, and from the dissolution of alien priories in the reign of Henry V., was freely bestowed by the kings of England, especially Henry VIII., not only upon spiritual persons and corporations, but upon laymen. Hence

it is that there are so many instances in England at the present time, of not merely the right to tithes, but the property of entire rectories being vested in laymen. These benefices are sometimes called lay, but more commonly impropriate, rectories, as being (according to Spelman) improperly in the hands of laymen. The rector is in that case termed the impropriator; but this appellation is now indiscriminately applied not only to lay individuals and corporations, but to all spiritual persons and corporations who, either by virtue of ancient appropriations, or by grants from the crown since the dissolution of the religious fraternities, are entitled to the tithes and other revenues of the Church, without performing any spiritual duties. By statute 32 Henry VIII. c. 7, the remedies which the law had provided in the ecclesiastical courts for the subtraction of tithes are communicated to laymen, and their title to tithes is put on the same footing with that to land, by giving them the same or similar actions for vindicating their estates in those and other ecclesiastical profits against all adverse claimants whatsoever. In short, tithes and other fruits of benefices, when vested in laymen, are liable to the same process of execution for debt, and subject to the same incidents of alienation, descent, escheat, and forfeiture as all other incorporated real property. Moreover, by statute 43 Eliz. c. 2, tithes impropriate are made liable to poor-rates. They are also included in the Land-tax Acts; and by the Statute of Limitations, 3 & 4 Will. IV. c. 27, actions and suits for their recovery are subject to the same periods of limitation as those for the recovery of land.

Another consequence of appropriation in England, besides the vesting of the possessions of the Church in laymen, was the endowment of vicarages. The appropriating corporations at first used to depute one of their own body to reside and officiate in the parish churches by turns or by lot, and sometimes by way of penance; but as this practice caused scandal to the Church, especially in the case of monastic orders whose rules were thereby violated, the monks by degrees ceased to officiate personally in the appropriated churches, and this duty was committed to stipendiary vicars or curates, who were however removable at the will of the appropriators. One of the numerous pretexts urged by the monastic bodies for obtaining appropriations had been that they might be the better enabled to keep up hospitality in their respective houses, and that they might relieve the poor. These duties however were so far neglected as to give rise to general discontent; in addition to which, the officiating priests were very poorly paid, and oppressed with hard service, and consequently unable to answer the calls of hospitality and charity. At length the legislature, by way of a partial remedy to these evils, enacted (15 Richard II. c. 6), "That in every licence for the appropriation of a parish church, it should be expressed that the diocesan bishop should ordain, in proportion to the value of the church, a competent sum to be distributed among the poor parishioners annually, and that the vicarage should be sufficiently endowed." Still, as the vicar was removable at pleasure, he was not likely to insist too strictly on the legal sufficiency of the endowment. Therefore, to establish the total independence of vicars of the appropriators, the statute 4 Henry IV. c. 12, provided, "That from thenceforth in every church appropriated there should be a secular person ordained vicar perpetual, canonically instituted and inducted, and convenably (fitly) endowed by the discretion of the ordinary, to do divine service, and to inform the people, and to keep hospitality there; and that no religious, that is, regular priest, should in anywise be made vicar in any church appropriated." From the endowments made in pursuance of this statute have arisen all the vicarages that exist at the present day. The title of the vicar to tithes and other ecclesiastical dues, such as Easter offerings (which are said to be due to the parson or vicar of common right), and customary payments for marriages, burials, and baptisms, depends primarily upon the deed of endowment. As however the rector and vicar are persons equally capable in law of holding such property, the deed is not always conclusive evidence in any question that may arise between these parties as to their respective rights; but it is said, that where either of them has for a long time had undisputed enjoyment of any particular portion of the tithes or other fruits of the benefice, which is not consistent with the terms of the original deed, a variation of that deed by some subsequent instrument may be presumed in favour of such long enjoyment. The endowments of vicarages have generally consisted of a part of the glebe-land of the parsonage, and what are technically called the small tithes of the parish. In some places, also, a portion of the great tithes has been added to the vicarages. [TITHES.]

A vicarage by endowment becomes a distinct benefice, of which the patronage is vested in the impropriator or sinecure rector, and is said to be appendant to the rectory. It follows that the vicar, being endowed with separate revenues, is enabled to recover his temporal rights without the aid of the patron. The loss of the original Act of Endowment is supplied by prescription; that is, if the vicar has enjoyed any particular tithes or other fruits by constant usage, the law will presume that he was legally endowed with them.

If the impropriator, either by design or mistake, presents the vicar to the parsonage, the vicarage will be dissolved, and the person presented will be entitled to all the ecclesiastical dues as rector. [VICARAGE.]

It is to be observed, that the statute 4 Henry IV. c. 12, did not extend to appropriations made before the first of Richard II. Hence it happens that in some appropriated churches no vicar has ever been endowed. In this case the officiating minister is appointed by the

impropriator, and is called a perpetual curate. He enters upon his official duties by virtue of the bishop's licence only, without institution or induction. It appears, moreover, that there were some benefices which, being granted for the purpose of supporting the hospitality of the monasteries (*in mensas monachorum*), and not appropriated in the common form, escaped the operation of the statute of Henry IV. In this case, the benefices were served by temporary curates belonging to the religious houses, and sent out as occasion required. When such appropriations, together with the charge of providing for the cure, were transferred (after the dissolution of monasteries) from spiritual societies to single lay persons (who, being incapable of serving them themselves, were obliged to nominate a person to the bishop for his licence to serve the cure), the curate by this means became so far perpetual as not to be removable at the pleasure of the impropriator, but only for such causes as would occasion the depriving of a rector or vicar, or by the revocation of the bishop's licence. Though the form of licences to perpetual cures expresses that they last only during the bishop's pleasure, the power of revocation, thus reserved to the bishop, has seldom, if ever, been exercised.

There is another kind of perpetual curacy which arises from the erection in a parish of a chapel of ease subject to the mother church. But the curacies of chapels of ease are not benefices in the strict legal sense of the word, unless they have been augmented out of the fund called Queen Anne's Bounty. The officiating ministers are not corporations in law with perpetuity of succession, as parsons, vicars, and other perpetual curates. Neither are chapels of ease subject to lapse, although the bishop may, by process in the ecclesiastical courts, compel the patrons to fill them up. But the statute 1 Geo. I. sess. 2, c. 10, provides that all churches, curacies, or chapels, which shall be augmented by the governors of Queen Anne's Bounty, shall be thenceforth perpetual cures and benefices, and the ministers duly nominated and licensed thereunto shall be in law bodies politic and corporate, and have perpetual succession, and be capable to take in perpetuity; and that if suffered to remain void for six months they shall lapse in like manner as presentative livings. [CHAPEL; CURATE.]

The district churches built in pursuance of the Church Building Acts, which form an almost unbroken series of statutes from 58 Geo. III. c. 45 to the present day, are perpetual cures, and the incumbents corporations.

A donative is a spiritual preferment, whether church, chapel, or vicarage, which is in the free gift of the patron, without making any presentation to the bishop, and without admission, institution, or induction by mandate from the bishop or any other; but the donee may by the patron, or by any other authorised by the patron, be put into possession. Nor is any licence from the bishop necessary to perfect the donee's title to possession of the donative, but it receives its full effect from the single act and sole authority of the donor. The chief further peculiarity of donatives is their exemption from episcopal jurisdiction. The visitation of donatives is by commissioners appointed by the patron. If the patron dies during the vacancy of a donative benefice, the right of nomination descends to his heir-at-law, and does not belong to his executors, as is the case with the patronage of presentative livings. Donatives, if augmented by Queen Anne's Bounty, become liable to lapse, and also to episcopal visitation. (1 Geo. I. sess. 2, c. 10.) But no donatives can be so augmented without the consent of the patron in writing, under his hand and seal. Both perpetual curates and incumbents of donatives are obliged to declare their assent to the Thirty-nine Articles and the Book of Common Prayer, and must take the oath of allegiance; and the right of patronage, both of perpetual curacies and donatives, is vindicated by writ of *Quare Impedit*.

Neither the augmentation nor the alienation of benefices with cure of souls has ever been favoured by the policy of the English law. To prevent the former was one of the objects of the statutes of Mortmain, one of which (23 Hen. VIII. c. 10) expressly makes void all assurances of lands in favour of parish churches, chapels, &c. [MORTMAIN.]

It might have been reasonably expected that, at the time of the dissolution of monasteries, the clergy would have received back those revenues which, being originally vested in them for religious purposes, had been subsequently appropriated by the monks. Such a measure, however, was not agreeable to the temper either of Henry VIII., or of his ministers and courtiers. When he came to a rupture with the pope, he resolved to free his dominions from the payment of first fruits and tenths to the papal treasury. The first of these taxes consisted of one year's whole profits of every spiritual preferment, according to a valuation of benefices made by the pope's authority; the second, of the tenth part of the annual profit of each benefice, according to the same valuation. The payment of these to the pope was prohibited by statute 25 Henry VIII. c. 20; but the impost was not abolished, for the next year by statute 26 Henry VIII. c. 3, the whole of the revenue arising therefrom was annexed to the crown. The last-mentioned statute directed these taxes to be paid according to a new valuation of ecclesiastical benefices to be made by certain commissioners appointed for the purpose. This valuation is what is still called the valuation of the king's books. The statute 26 Henry VIII. c. 3, was confirmed by statute 1 Eliz. c. 4. [FIRST FRUITS.]

The subsequent proceedings of Henry VIII., after the appropriation of the possessions of the monasteries, tended rather to enrich the

collegiate and other corporations aggregate with the revenues of the Church, than to revest them in their ancient possessors. Nor was the latter object the aim of his successors, until more than a century after his death; but after the restoration of Charles II., the scandal of lay impropriations gave rise to some relaxation of the statutes of mortmain. Thus by statute 17 Car. II. c. 3, power was given to lay impropriators of tithes to annex such tithes to, or settle them in trust for, the parsonage or vicarage of the parish church to which they belonged, or for the perpetual curate, if there was no vicarage endowed; and by the same statute, in cases where the settled maintenance of the parsonage or vicarage, with cure, did not amount to the full sum of 100*l.* a-year, clear of all charges and reprises, the incumbent was empowered to purchase for himself and his successors, lands and tithes, without licence of mortmain. Another statute of the same reign (29 Car. II. c. 8) confirms, for a perpetuity, such augmentations of vicarages and perpetual curacies as had been already made for a term of years by ecclesiastical corporations, on granting leases of impropriate rectories. The Act also confirms future augmentations to be made in the same manner, subject to a limitation which has since been taken off by statute 1 & 2 Will. IV. c. 45, by which the provisions of 29 Car. II. c. 8 have been considerably extended. But the principal augmentation of the revenues of the Church was made under the provisions of the statute 2 & 3 Anne, c. 11. By this Act, and by the queen's letters-patent made in pursuance of it, all the revenue of the first fruits and tenths was vested in trustees, for the augmentation of small benefices. This fund is what is usually called Queen Anne's Bounty, the administration of which has been regulated by several statutes.

The trustees, who are certain dignitaries of the Church, and other official personages for the time being, are incorporated by the name of "the governors of the Bounty of Queen Anne, for the augmentation of the maintenance of the poor clergy," and have authority to make rules for the distribution of the fund, which rules are to be approved of by the crown under the sign manual. Every person having any estate or interest in possession, reversion, or contingency, in lands or personalty, is empowered to settle such estate or interest, either by deed enrolled or will, upon the corporation, without licence of mortmain; and the corporation are empowered to admit benefactors to the fund into their body. Agreements made with benefactors to Queen Anne's Bounty, concerning the right of patronage of augmented churches in favour of such benefactors, where the agreements are made by persons or bodies corporate having such an interest in the patronage of such churches as the Act renders necessary are made valid; but an agreement by a parson or vicar must be made with consent of his patron and ordinary. The governors are also empowered by the same statute to make agreements with patrons of donatives or perpetual cures for an augmented stipend to the ministers of such benefices when augmented, to augment vacant benefices, and with the concurrence of the proper parties, to exchange lands settled for augmentation.

It should be observed that a modern statute of mortmain, the Statute of Charitable Uses, 9 Geo. II. c. 36, imposed certain forms, a strict compliance with which was necessary in all gifts to Queen Anne's Bounty, whether by deed or will. But these restrictions have been removed by statute 43 Geo. III. c. 107, as far as respects gifts of real property for augmentation of the bounty; and a recent provision for the augmentation of benefices not exceeding 150*l.* per annum is made by 46 Geo. III. c. 133, which discharges all such benefices from the land-tax, without any consideration being given for the discharge, with a proviso that the whole annual amount thus remitted shall not exceed 6000*l.*

The alienation of the temporalities of benefices, even in perpetuity, was not forbidden by the common law, provided it were made with the concurrence of the principal parties interested, namely, the parson, patron, and ordinary. Thus, at the common law, lands might have become exempt from the payment of tithe by virtue of an agreement entered into between the tithe-payer and the parson or vicar, with the necessary consent, for the substitution of land in lieu of tithe. But the statute 13 Eliz. c. 10 prohibits, among other bodies corporate, parsons and vicars from making any alienation of their temporalities beyond the life of the incumbent, except by way of lease for twenty-one years, or three lives, "whereupon the accustomed yearly rent or more shall be reserved and payable yearly during the said term." Further restrictions are imposed by the statute 18 Eliz. c. 11, which requires that where any former lease for years is in being, it must be expired, surrendered, or ended within three years next after the making of the new lease, and all bonds and covenants for renewing or making leases contrary to this and the last-mentioned statute are made void. The statute 14 Eliz. c. 11, as to houses in towns, extends the term specified in the 13 Eliz. c. 10 to forty years, but prohibits leases of such houses in reversion, and allows of absolute alienation by way of exchange. But the consent of patron and ordinary is still necessary in order to make the leases of parsons and vicars binding upon their successors. It is said that about the time when these statutes were passed, it was a practice for patrons to present unworthy clergymen to their vacant benefices, on condition of having leases of those benefices made to themselves at a very low rate. The consequences of this were not unlike what ensued from the appropriation of benefices by monastic corporations; the incumbents did not reside, and the churches were indifferently served by stipendiary curates. To remedy this evil,

it was provided by statute 13 Eliz. c. 20 (made perpetual by 3 Car. I. c. 4), that no lease of a benefice with cure should endure longer than while the lessee should be ordinarily resident and serving the cure, without absence for more than eighty days in any one year, but should immediately, upon non-residence, become void; and that the incumbent should forfeit one year's profits of the benefice, to be distributed among the poor; but the statute contains an exception of the case where a parson, allowed by law to have two benefices, demises the one, upon which he is not most ordinarily resident, to his curate. The 18 Eliz. c. 11, provides that process of sequestration shall be granted by the ordinary to obtain the profits so forfeited. By statute 14 Eliz. c. 11, bonds and covenants, and by statute 43 Eliz. c. 9, judgments entered into or suffered in fraud of the statute 13 Eliz. c. 20, are made void.

The 13 Eliz. c. 20, also renders void all charges upon ecclesiastical benefices by way of pension or otherwise. This last provision has been held to extend to mortgages and annuities, even if made only for the life or incumbency of the mortgager. But the strictness of the laws prohibiting all alienations by or in favour of ecclesiastical persons, has in modern times been somewhat relaxed by the legislature for purposes of public convenience, such as the General Inclosure Acts. Other statutes empower ecclesiastical incumbents, with consent of patron and ordinary, to raise money by sale or mortgage of the profits of the benefice, for a term, for the purpose of building and repairing parsonage houses; and the governors of Queen Anne's Bounty are permitted to advance money for the same object. Incumbents, with consent of patron and ordinary, may exchange their parsonage houses and glebe lands, and purchase and annex to their benefice other parsonage houses and glebe lands. Rectors and vicars are also enabled to charge their benefices in favour of chapels of ease within their cures.

Although an ecclesiastical benefice cannot be alienated for the satisfaction of the incumbent's debts, the profits may be sequestered for that purpose. [SEQUESTRATION.]

The duties and liabilities of spiritual persons come more properly under the head of CLERGY, but it is not inconsistent with the subject of the present article to mention the non-residence of spiritual persons upon their benefices, which (besides being cognisable in the ecclesiastical courts) is visited with severe penalties by different acts of parliament. The principal of the old enactments on the subject is stat. 21 Hen. VIII. c. 13 (amended and enlarged by 25 Hen. VIII. c. 16, 28 Hen. VIII. c. 13, and 33 Hen. VIII. c. 28), which imposes certain penalties upon persons wilfully absenting themselves from their benefices for one month together, or two months in the year.

But this act excepts the chaplains to the king and royal family, those of peers, peeresses, and certain public officers, during their attendance upon the household of such as retain them; and also all heads of colleges, magistrates, and professors in the universities, and all students under a certain age residing there *bonâ fide* for study. And the king may grant dispensations for non-residence to his chaplains, even when they are not attending his household. The residence intended by the law must be in the parsonage house, if there be one; but if there be no house of residence, the incumbent must reside within the limits of the benefice, or of the city, town, or parish where the benefice is situate, provided such residence be within two miles from the church or chapel of the benefice; and in all such cases a residence may be appointed by the bishop, even without the limits of the benefice. These acts (which extend also to archdeaconries, deaneries, and dignities in cathedral and collegiate churches) have been consolidated and amended by stat. 57 Geo. III. c. 99. By this act, every incumbent absenting himself from a benefice with cure, without licence, for the period of three months consecutively, or at several times for so many days as are equal to this period, and abiding elsewhere than at some other benefice, forfeits for an absence exceeding three months, but not above six months, one-third of the annual value of the benefice, clear of all outgoings except the curate's salary. Absences of a longer duration are subjected to proportional penalties, and the whole of the penalty in each case is given to the party suing, together with such costs as are allowed by the practice of the court where the action is brought. All who were exempt from residence before the last statute are still exempt, and the exemption is extended to several others, including public officers in either of the two universities, and tutors and public officers in any college. Students in the university are exempted till they are thirty years of age; and the royal prerogative to grant dispensations for non-residence to his chaplains is not affected by the statute. But no person can have the benefit of an exemption unless he makes a notification of it every year, within six weeks from the 1st of January, to the bishop of the diocese. Besides the exemptions, the bishop may grant a licence for non-residence for the illness or infirmity of an incumbent, his wife, or child, or for other causes specified in the Act; and if the bishop refuses a licence, the incumbent may appeal to the archbishop. The bishop may also grant licences for non-residence for causes not specified in the Act, but in that case the licences must be allowed by the archbishop. Licences may be revoked, and no licence can continue in force above three years from the time of its being granted, or after the 31st of December in the second year after that in which it is granted. The Act also contains directions with respect to the lists of exemptions and licences for non-residence, which are to be kept in the registry of each diocese for public inspection.

The Act 57 Geo. III. c. 99 provides also for the appointment of licensed curates in benefices, the incumbents of which are absent with or without licence or exemption, and regulates the salaries of such curates upon a scale proportioned to the value of each benefice and the number of the population within its precincts; and in all cases of non-residence from sickness, age, or other unavoidable cause, the bishop may fix smaller salaries at his discretion.

There are other liabilities which parsons, vicars, and other spiritual persons necessarily incur in respect of their benefices. Thus, by 43 Eliz. c. 2, they are rateable in respect of their benefices for the relief of the poor; and although the burden of the repairs of the body of the church falls upon the parishioners, the rector (and, where the parsonage is appropriated, the impropriator) is liable for the repairs of the chancel. And the stat. 35 Ed. I. sess. 2, the object of which was to prohibit rectors from cutting down trees in churchyards, contains an express exception of the case where such trees are wanted for the repair of the chancel.

Besides the liability implied in the last-mentioned prohibition, all ecclesiastical incumbents are liable for dilapidations. A dilapidation is said to be the pulling down or destroying in any manner any of the houses or buildings belonging to a spiritual living, or suffering them to run into ruin or decay, or wasting or destroying the woods of the church, or committing or suffering any wilful waste in or upon the inheritance of the church. Such proceedings may be prevented by the spiritual censures of the ordinary; and the profits of the benefice may be sequestered until the damage be repaired; and the Court of Chancery will, at the suit of the patron, grant an injunction to restrain this as well as every other species of waste; or the next incumbent may recover damages for dilapidations either in the Spiritual Court or in an action at common law against his predecessor, or, if he be dead, against his personal representatives.

The remedies for the subtraction of tithes given by the law of England to the clergy are sufficiently ample. The stat. 2 & 3 Ed. VI. enables them to recover the tithes in the Spiritual Courts; while modern statutes, and particularly 53 Geo. III. c. 127, and 7 Geo. IV. c. 15, have given a summary remedy for the recovery of tithes under a certain amount before two justices of the peace, who are empowered to levy them by distress. But questions of title to tithes belong to the temporal courts only, a subject which will be more properly considered under the head of TITHES.

With respect to actions and suits for recovery of lands or rents by parsons, vicars, or other spiritual corporations sole, the stat. 3 & 4 Will. IV. c. 27 subjects them to the period of limitation of two successive incumbencies, together with six years after the appointment of a third person to the benefice, or in case of this period not amounting to sixty years, then to the full period of limitation of sixty years.

Having thus shown how possession of the different kinds of benefices in England is acquired and maintained, and what are the principal legal incidents of such possession, it remains to consider how benefices may be vacated or avoided. And this may happen several ways: 1. By the death of the incumbent. 2. By resignation, which is made into the hands of the ordinary, except in the case of donatives, which must be resigned into the hands of the patron, who alone has jurisdiction over them. The resignation must be absolute, unless it be for the purpose of exchange, in which case it may be made on the condition that the exchange shall take full effect. Where two parsons wish to exchange benefices, they must obtain a licence from the ordinary to that effect; and if the exchange is not fully executed by both parties during their lives, all the proceedings are void. 3. A benefice may be avoided by the incumbent's being promoted to a bishopric; but the avoidance in this case does not take place till the actual consecration of the new prelate. The patronage of the benefice so vacant belongs for that turn to the crown, except in the case of a clergyman, beneficed in England, accepting an Irish bishopric; for no person can accept a dignity or benefice in Ireland until he has first resigned all his preferments in England; so that in this case the patron, and not the crown, has the benefit of the avoidance. If the incumbent of a donative be promoted to a bishopric, no cession takes place; and it seems that he may retain the donative without a commendam.

4. If an incumbent of a benefice with cure of souls accepts a second benefice of a like nature without procuring a dispensation, the first, by the provisions of the canon law, is so far void, that the patron may present another clerk, or the bishop may deprive; but till deprivation no advantage can be taken by lapse. And the stat. 21 Henry VIII. c. 13 provides, that where a person, having a benefice of the value of 8*l.* per annum or upwards, according to the valuation of the king's books, accepts any other, the first shall be adjudged void, unless he obtains a dispensation in conformity with the provisions of the statute. And dispensations not in conformity with the statute are declared void, and heavy penalties are imposed upon persons endeavouring to procure them. But by virtue of such dispensations, spiritual persons of the king's council may hold three benefices with cure, and the other persons qualified by the statute to receive dispensations may each hold two such benefices. The statutes 1 & 2 Vict. c. 106, amended by 13 & 14 Vict. c. 98, have however provided that two benefices cannot be held by the same person, unless they be within three miles of each other, and the value of one does not exceed 100*l.*

The persons who may receive dispensations are the king's chaplains,

those of the queen and royal family, and other persons who are allowed by the statute to retain a certain number of chaplains, and also the brethren and sons of all temporal lords, the brethren and sons of knights, and all doctors and bachelors of divinity and law, admitted to their degrees in due form by the universities. The privilege is not extended to the brethren and sons of baronets, as the rank of baronet did not exist at the time when the statute was passed. [CHAPLAIN.]

The statute expressly excepts deaneries, archdeaconries, chancellorships, treasurerships, chanterhips, prebends, and sinecure rectories. Donatives are within the statute, if a donative is the first living; but if a donative is the second living taken without a dispensation, the first is not made void by the statute, the words of which are "instituted and inducted to any other," words not applicable to donatives. But it seems that both in the cases excepted by the statute, and in the case where the second living is a donative, a dispensation is equally necessary in order to hold both preferments, as otherwise the first would be voidable by the canon law.

The stat. 36 Geo. III. c. 83 has brought chapels and churches, augmented by Queen Anne's bounty, within the Statute of Pluralities, by enacting that such churches and chapels shall be considered as presentative benefices, and that the licence to serve them shall render other livings voidable in the same manner as institution to presentative benefices. It appears that both by the common law, and by the provisions of stat. 37 Hen. VIII. c. 21, and 17 Car. II. c. 3, a union or consolidation of two benefices into one might with consent of patrons, ordinaries, and incumbents, be made in such a manner as not to be affected by the Statute of Pluralities.

For the manner of obtaining dispensations from the archbishop, and for the form of such dispensations, and the confirmation thereof by the lord chancellor, and the provisions which the canon law requires to be inserted in such dispensations, see Burn's 'Eccles. Law,' title 'Plurality.'

5. Another mode of avoidance of a benefice, is by deprivation under a sentence of an ecclesiastical court. The principal causes on which sentence of deprivation is usually founded, are heresy, blasphemy, gross immorality; or conviction of treason, murder, or felony.

6. A benefice may be avoided by act of the law; as where the incumbent omits or refuses to subscribe the Thirty-Nine Articles, or declaration of conformity to the Liturgy, or to read the Articles or Book of Common Prayer, in pursuance of the statutes which render those acts necessary. But the most remarkable mode of avoidance which is to be classed under this head, is that for simony, in pursuance of the stat. 31 Eliz. c. 6. By this statute for the avoiding of simony, it is among other things enacted, that if any patron, for any sum of money, reward, profit, or benefit, or for any promise, agreement, grant, bond, or for any sum of money, reward, gift, profit, or benefit, shall present or collate any person to an ecclesiastical benefice with cure of souls or dignity, such presentation or collation shall be utterly void, and the crown shall present to the benefice for that turn only. The statute also imposes a penalty upon the parties to the simoniacal contract to the amount of double the value of a year's profit of the benefice, and for ever disables the person corruptly procuring or accepting the benefice from enjoying the same. And by stat. 12 Anne, sess. 2. c. 12, a purchase by a clergyman, either in his own name or that of another, of the next presentation for himself, is declared to be simony, and is attended with the same penalties and forfeiture as are imposed by the statute of Elizabeth. Upon the construction of this statute of Elizabeth it has been held, that if the next presentation can be shown to have been purchased with the intention of presenting a particular person, who, upon a vacancy taking place, is presented accordingly, this fact is sufficient to render the transaction simoniacal. An exception has however been made in the case of a father providing for his son by the purchase of a next presentation, but the principle of this exception has lately been denied.

The circumstance of the incumbent being at the point of death at the time of the contract, may also vitiate the transaction: except where the fee simple of the advowson is purchased, in which case it has been decided that the knowledge of the state of the incumbent's health does not make the purchase simoniacal.

It has been a question much agitated in our courts, whether a presentation is valid where the person presented enters into a bond or agreement, either generally to resign the benefice at the patron's request, or to resign it in favour of a particular person specified in the instrument. After several contrary decisions in the courts below, it was finally decided by the House of Lords towards the latter end of the last century, that general bonds of resignation were simoniacal and illegal. A similar decision has since been made by the same tribunal with respect to bonds of resignation in favour of specified persons. As there is no objection on the grounds of public policy to the last-mentioned instruments, if restrained within due limits, the interference of the legislature has been thought necessary in order to regulate transactions of this nature. On this account, after a retrospective Act (7 & 8 Geo. IV. c. 25) had been passed, to remedy the hardships that might otherwise have been occasioned by the last-mentioned judgment of the House of Lords, it was finally enacted by the 9 Geo. IV. c. 94, that every engagement, *bond fide* made for the resignation of any spiritual office or living, in favour of a person, or one of two persons to be specially named therein, being such persons as were mentioned

in a subsequent section of the Act, should be valid and effectual in the law, provided such engagement were entered into before the presentation of the party entering into the same. By the section referred to, where two persons are specially named in the engagement, each of them must be, either by blood or marriage, an uncle, son, grandson, brother, nephew, or grandnephew of the patron (provided the patron is not a mere trustee), or of the person for whom the patron is a trustee, or of the person by whose direction the presentation is intended to be made, or of any married woman whose husband in her right is patron, or of any other person in whose right the presentation is intended to be made. The deed containing the engagement to resign must be deposited for inspection with the registrar of the diocese wherein the benefice is situated, and every resignation made in pursuance of such an engagement must refer to the same, and state the name of the person for whose benefit it is made and becomes void, unless that person is presented within six months. The statute is limited in its operation to cases where the patronage is strictly private property.

There are certain benefices of which the patronage is either by custom or act of parliament vested in certain public officers or corporations. Thus, the lord chancellor has the absolute patronage of all the king's livings which are valued at 20*l.* per annum or under in the king's books. It is not known how this patronage of the chancellor was derived; but it appears from the rolls of parliament in the 4th Ed. III., that the chancellor at that time had the patronage of all the king's livings of the value of 20 marks or under, and it is not improbable that at the time of making the new valuation of benefices in the reign of Henry VIII., a new grant was made to the chancellor by the crown, in consideration of the altered value of ecclesiastical property. By stat. 3 James I. c. 5, popish recusants are disabled from exercising any right of ecclesiastical patronage; and the patronage of livings in the gift of such persons is vested in the two universities, according to the several counties in which the livings are situate. This disability was confirmed by the subsequent statutes 1 Will. & Mary, c. 26, 12 Anne, sess. 2 c. 14, and extended to cases where the right of patronage was vested in a trustee for a papist; and is not removed (along with the other disabilities affecting Roman Catholics) by stat. 10 Geo. IV. c. 7. But the last-mentioned act provides, that where any ecclesiastical patronage is connected with any office in the gift of the crown, which office is held by a Roman Catholic, the patronage, so long as the office is so held, shall be exercised by the Archbishop of Canterbury.

The Church of Ireland being the same with that of England, the ecclesiastical polity of each is in its main principles the same. The same law of ecclesiastical patronage, the same classification of benefices, the same circumstances of lay impropriations, and, in short, the same ecclesiastical privileges and disabilities may prevail in each country. But a most important alteration in the distribution of the revenues of the Irish Church was effected by the 3 & 4 Will. IV. c. 37, amended by 4 & 5 Will. IV. c. 90. By this Act, certain ecclesiastical commissioners are established as a corporation, for the augmenting of small livings out of the funds, which come into their hands by virtue of the Act, and for other ecclesiastical purposes. The funds in question arise, partly from the revenues of certain bishoprics which are abolished, and the surplus revenues of the rest above certain limits fixed by the Act; partly from the money paid by the tenants of lands held under bishops' leases renewable for ever, for a conversion of such leasehold interest into a perpetuity; and partly from a tax levied on all ecclesiastical dignities and benefices, according to a scale of taxation specified in a schedule to the Act; in consideration of which tax all first fruits are abolished. The commissioners are invested with extraordinary powers by the Act. Thus, they have authority to disappropriate benefices united to dignities, and to unite them to vicarages in lieu thereof. They have also the power of suspending the appointment to benefices which are in the gift either of the crown, of archbishops, bishops, or other dignitaries, or of ecclesiastical corporations, where it appears that divine service has not been performed within such benefices for three years before the passing of the Act. The subject of the better regulation of the revenues and discipline of the Irish Church occasionally engages the attention of the legislature.

We have mentioned the attempts of the popes to acquire the right of patronage to all ecclesiastical benefices in Europe, and the successful measures that were taken in England for resisting their pretensions. After ineffectual attempts had been made at the councils of Constance and Basle, in 1414 and 1433, to check the papal encroachments, each of the principal European governments seems to have asserted in some measure its own ecclesiastical independence, either by entering into concordats with the pope, or assuming the right of controlling his pretensions by national legislation. The latter course seems to have been adopted by Spain towards the end of the 15th century. (Hallam's 'Middle Ages,' vol. ii. p. 361.) The emperor of Germany in 1448 entered into a concordat at Aschaffenburg with the pope, which is said to be still the law of the Catholic states of Germany. By this treaty, the pope obtained the right of collation to all benefices that fell vacant during six alternate months of the year. By the Pragmatic Sanction of Charles VII. of France, published in 1438, all mandates and reservations with respect to benefices in that country were abolished for the future. This ordinance was followed, in the beginning of the 16th century, by the concordat of Francis I. and Leo X., which remained till the time of

the French revolution a fundamental law of the Gallican Church. By this treaty the pope gave up his indefinite claims to the patronage of benefices, and received a small stipulated patronage in return; and the substantial part of the patronage of bishoprics was vested in the crown. The modern concordat of Pius VII. with Napoleon, though destructive of the liberties of the Gallican Church, does not appear, so far as respects the right of the pope to interfere with the patronage of benefices, to be a material innovation upon the concordat of Francis I. [CONCORDAT.]

For the numerous abuses with respect to the patronage, acquisition, and transmission of benefices that prevailed in the Roman Catholic Church, especially in Italy, during the 15th and 16th centuries, see Father Paul's 'Treatise on Benefices,' cap. 44-46.

BENEFICIUM, a Latin word, literally, "a good deed;" also "a favour," "an act of kindness." ('Seneca de Beneficiis,' l. iii. c. 18.) This word had several technical significations among the Romans.

When a proconsul, prætor, or quæstor, returned to Rome from his province, he first gave in his accounts to the treasury; after which he might also give in the names of such persons as had served under him in the province, and by their conduct had deserved well of the state. To do this was expressed by the phrase, "in beneficiis ad ærarium deferre,"—"to give into the treasury the names of deserving persons;" and in the case of certain officers and persons, this was to be done within thirty days after the proconsul, &c., had given in his accounts. The object of this practice was apparently to recommend such individuals to public notice and attention, and in many cases it would be a kind of introduction to future honours and emoluments. It does not seem quite certain if money was given to those thus recommended in the time of Cicero (Cicero, 'ad Divers.' V. 20. 'Pro Archia,' 5.) Beneficium, in another sense, means some honour, promotion, or exemption from certain kinds of service, granted by a Roman governor or commander to certain of his soldiers, hence called Beneficiarii. (Cæsar, 'de Bello Civili,' i. 75, iii. 88; Sueton. 'Tiber.' 12; Festus sub verb. 'Beneficiarii.') Numerous inscriptions given in Gruter, show how common this practice was: in some of them the title is represented by the initial letters B. F., only; Beneficiarius Legati Consularis (li. 4); B. F. Proconsulis (cxxx. 5), &c. Under the emperors, beneficia appear to have signified any kind of favours, privileges, or emoluments granted to a subject by the sovereign; and Suetonius observes ('Titus,' 8) that all the Cæsars, in conformity with a regulation of Tiberius, considered that, on their accession to the supreme power, all the grants (beneficia) of their predecessors required confirmation, but Titus by one edict, without solicitation, confirmed all grants of previous emperors. The grants made by the emperors, which were often lands, were entered in a book called the Liber Beneficiorum, which was kept by the chief clerk of benefices, under the care of the Comes Rerum Privatarum of the emperor; or it was kept by a person entitled "A Commentariis Beneficiorum," or clerk of the benefices, as we learn from a curious inscription in Gruter. (DLXXVIII. 1.) This, which is a monumental inscription, is in memory of M. Ulpius Phædimus, who among other offices held that of clerk of benefices to Trajan: the monument was erected in the reign of Hadrian, A.D. 131, by Valens Phædimianus, probably one of the same family, who styles himself wardrobe-keeper (a veste).

Beneficium, in the civil law, signifies any particular privilege: thus it is said ('Dig.' i. 4. 3.) that the beneficium of the emperor must be interpreted very liberally; and by the Julian law, *de bonis cedendis*, a debtor was said to receive the benefit (beneficium) of not being taken to prison. (C. vii. 71, 1.)

Beneficium, among the writers of the middle ages, signified any grant of land from the fiscus, that is, the private possessions of the king or sovereign, or any other person, for life; so called, says Ducange, because it was given out of the mere good will (beneficium) and that liberality of the grantor. But it is evident, from what we have said, this kind of grant was called beneficium after the fashion of the grants of the Roman emperors; a view which has been supported directly by Palgrave ('Rise and Progress of the British Constitution,' vol. i. p. 356) and indirectly by Hallam, who, in the first volume of 'The History of Europe during the Middle Ages,' c. ii., has controverted with great force and learning the position of nearly all the old writers on the feudal system, that benefices were originally precarious and revoked at pleasure by the sovereign. A beneficiary grant in the middle ages appears to have been properly a grant for life, that is, a grant to the individual, and accordingly corresponds to *usufructus*, and is opposed to *proprietas*. The name beneficium, as applied to a feudal grant, was afterwards changed for that of feudum; and the terms beneficium and feudum are often used indifferently in writings which treat of feuds [FEUD]. For further remarks on the term beneficium, see Ducange. 'Glossarium,' &c.; Hotman, 'Commentarius Verborum Juris, Opera.' Lugd. fol. 1599: and Spelman 'on Feuds,' c. iii.

BENEFIT OF CLERGY. The privilege or exemption thus called had its origin in the regard which was paid by the various sovereigns of Europe to the early Christian Church, and in the endeavours of the popes to withdraw the clergy altogether from secular jurisdiction. In England, these attempts, being vigorously resisted by our earlier kings after the Conquest, only succeeded partially and in two particular instances: namely, in procuring, 1. the exemption of places consecrated to religious purposes from arrests for crimes, which was the origin of sanctuaries [SANCTUARY]; and, 2. the exemption of clergy-

men in certain cases from criminal punishment by secular judges. From the latter exemption came the benefit of clergy, which arose when a person indicted for certain offences pleaded that he was a clerk or clergyman, and claimed his *privilegium clericale*. Upon this plea and claim the ordinary appeared and demanded him; a jury was then summoned to inquire into the truth of the charge, and according to their verdict the accused was delivered to the ordinary, either as *acquitted* or *convicted*, to undergo canonical purgation, and then to be discharged or punished according to the result of the purgation. This privilege, however, never extended to high treason nor to offences not capital, and wherein the punishment would not affect the life or limb of the offender (*quæ non tangunt vitam et membrum*). It is singular that before the stat. 3 & 4 Will. III., which expressly includes them, this privilege of clergy never extended by the English law to women, although, by the canon law, nuns were exempted from temporal jurisdiction.

In the early period of our history, the benefit of clergy was not allowed, unless the prisoner appeared in his clerical habit and tonsure; but in process of time, as the original object of the privilege was gradually lost sight of, this ceremony was considered unnecessary, and the only proof of clergy required was his showing to the satisfaction of the court that he could read; a rare accomplishment, except among the clergy, previously to the 15th century. The consequence was, that at length all persons who could read, whether clergymen or lay clerks, as they were called in some ancient statutes, were admitted to the benefit of clergy in all prosecutions for offences to which the privilege extended. The mode in which this test of reading was applied is thus described by Sir Thomas Smith, in his 'Commonwealth of England,' written in 1565. "The bishop," says he, "must send one with authority under his seal to be a judge in that matter at every gaol delivery. If the condemned man demandeth to be admitted to his book, the judge commonly giveth him a Psalter, and turneth to what place he will. The prisoner readeth so well as he can (God knoweth sometime very slenderly), then he (the judge) asketh of the bishop's commissary, *Legit ut clericus?* The commissary must say *legit* or *non legit*, for these be words formal, and our men of law be very precise in their words formal. If he say *legit*, the judge proceedeth no further to sentence of death; if he say *non*, the judge forthwith proceedeth to sentence."

The clergy, however, do not appear to have universally admitted that the mere fact of a prisoner's ability to read was to be taken as a conclusive proof of his clerical character. A curious case is recorded in the 'Year Book,' 34 Hen. VI. 49 (1455), which greatly puzzled the judges: A man indicted of felony claimed the benefit of clergy; upon which the archdeacon of Westminster Abbey was sent for, who showed him a book, in which the felon read well and fluently. Upon hearing this, the court ordered him to be delivered to the archdeacon on behalf of the ordinary; but the archdeacon refused to take him, alleging that the prisoner was not a clerk. This raised a serious difficulty; and the question was one of particular importance to the prisoner, as the judges deliberated whether he must not of necessity be hanged. He was, however, remanded to prison, and the subject was much discussed by the judges for several terms; but, luckily for the culprit, the conscientious archdeacon being removed, his successor heard the prisoner read, and consented to receive him; whereupon he was delivered to the ordinary, the judges saying "that *in favorem vite et libertatis ecclesie*, even where a man had once failed to read, and had received sentence of death, they would allow him his benefit of clergy, under the gallows, if he could then read, and was received by the ordinary." Another case is recorded in the 21 Edw. IV. (1481), in which a felon read well and audibly in the presence of the whole court; but the ordinary declared "*non legit ut clericus* for divers considerations;" upon which judgment was given that he should be hanged; "And so," says the reporter, "he was, *ut audiui*." ('Year Book,' 21 Edw. IV. 21.) But though a felon might claim the benefit of clergy to the last moment of his life, it was an indictable offence to teach him to read for the purpose of saving him. Thus in the 7 Ric. II. (1383), the vicar of Round Church in Canterbury was arraigned and tried, "for that by the license of the jailer there, he had instructed in reading one William Gore, an approver, who at the time of his apprehension was unlearned" (*ineruditus in lecturâ*). (Dyer's 'Reports,' p. 206.) It may readily be conceived that questions between the temporal courts and the ordinary would arise as the art of reading became more generally diffused; and it was probably on this account that an express provision was made by the legislature, in order in some degree to obviate the occurrence of such difficulties. The statute 4 Henry VII. c. 13 (1488), revived the distinction between actual clergymen and such persons as had accidentally acquired a competent skill in reading, by providing that no person once admitted to the benefit of clergy should a second time be allowed the same privilege, unless he produced his orders; and to mark those who had once claimed the privilege, the statute enacted that all persons, not in orders, to whom it was so allowed, should be marked upon the "brawn of the left thumb," in the court, before the judge, before such person was delivered to the ordinary. After the offender was thus burned in the hand, he was formally delivered to the ordinary to be dealt with according to the ecclesiastical canons, and to make purgation by undergoing the farce of a canonical trial. This second trial took place

before the bishop or his deputy; there was a jury of twelve persons, who gave their verdict on oath; witnesses were examined on oath; the prisoner answered on oath; and twelve compurgators swore that they believed him. On this occasion, though the prisoner had been convicted at common law by the clearest evidence, or had even confessed his guilt, he was almost invariably acquitted. The whole proceeding before the ordinary is characterised by Chief Justice Hobart at the beginning of the 17th century, "as turning the solemn trial of truth by oath into a ceremonious and formal lye." (Hobart's 'Reports,' p. 291.) To remove this discreditable abuse of the forms of justice, the statute 18 Eliz. c. 7, enacted, that in all cases after an offender had been allowed his clergy, he should not be delivered to the ordinary, but be at once discharged by the court, with a provision that he might be detained in prison for any time not exceeding a year, at the discretion of the judge before whom he was tried.

By various statutes passed in the course of the last century, the court before which an offender was tried and admitted to his clergy were empowered to commute the burning in the hand for transportation, imprisonment, or whipping; and subsequently to the passing of these statutes it is believed that no instance has occurred of a convict being burned in the hand.

The practice of calling upon a convicted person to read in order to prove to the court his title to the benefit of clergy continued until a comparatively late period. A case is mentioned in Kelynge's 'Reports,' p. 51, which occurred in 1666, where the bishop's commissary had deceived the court by reporting, contrary to the fact, that a prisoner could read; upon which Chief Justice Kelynge rebuked him severely, telling him "that he had unpreached more that day than he could preach up again in many days," and fined him five marks. At length the statute of the 5th of Anne, c. 6, enacted that the benefit of clergy should be granted to all those who are entitled to it without requiring them to read; and thus the "idle ceremony of reading," as Mr. Justice Foster justly terms it, was finally abolished. Till comparatively recently, every felon on conviction for a capital offence was accordingly told to go down on his knees and "pray his clergy," in the absence of which ceremony, it was supposed that the judge could not avoid passing sentence of death.

The absurd and perplexing distinctions which the continuance of this antiquated and worn-out clerical privilege had introduced, having become extremely detrimental to the due administration of justice, it was abolished by statute 7 & 8 Geo. IV., c. 28. Doubts having been raised, whether the provision of 1 Edw. IV., c. 2, retaining the benefit of clergy to lords of parliament and peers of the realm, might not still be in force, a subsequent statute put its entire abolition beyond question, 4 & 5 Vict. c. 22. The subject is now of no practical importance; but those who may be inclined to pursue it as a matter of historical curiosity may find the following references useful: Blackstone's 'Commentaries,' vol. iv. chap. 28; Hale's 'Pleas of the Crown,' part ii. c. 45; Barrington's 'Observations on Ancient Statutes,' Hobart's 'Reports,' p. 288.

BENEFIT SOCIETIES. [FRIENDLY SOCIETIES.]

BENEVOLENCE, a species of forced loan or gratuity, and one of the various arbitrary modes of obtaining supplies of money, which, in violation of Magna Charta, were formerly resorted to by the kings of England. The name implies a free contribution, with or without the condition of repayment; but so early as the reign of Edward IV. the practice had grown into an intolerable grievance. That king's lavish liberality and extravagance induced him to levy benevolences very frequently; and one of the wisest and most popular acts of his successor, Richard III., was to procure the passing of a statute (cap. 2) in the only parliament assembled during his reign, by which benevolences were declared to be illegal; they were denounced as "new and unlawful inventions," and as "the cause of great penury and wretchedness;" but this statute did not clearly forbid the solicitation of voluntary gifts, and Richard himself afterwards violated its provisions. Henry VII. exacted benevolences, which were enforced in a very oppressive way. Archbishop Morton, who solicited merchants and others to contribute, employed a piece of logic which obtained the name of "Morton's fork." He told those who lived handsomely, that their opulence was manifested by their expenditure; and those who lived economically, that their frugality must have made them rich; so that no class could evade him. Cardinal Wolsey, among some other daring projects to raise money for Henry VIII., proposed a benevolence, which the citizens of London objected to, alleging the statute of Richard III.; but the answer was, that the act of a usurper could not oblige a lawful sovereign. Elizabeth also "sent out her privy seals," for so the circulars demanding a benevolence were termed; but though individuals were committed to prison for refusing to contribute, she repaid the sums exacted. Lord Coke, in the reign of James I., is said to have at first declared that the king could not solicit a benevolence, and then to have retracted his opinion, and pronounced upon its legality.

The subject underwent a searching investigation during the reign of Charles I., as connected with the limitation of the king's prerogative. Writs were issued under the privy seal for the collection of a general loan from every individual, and the collectors had private instructions to require not less than a certain proportion of each man's property in land or goods, and had extraordinary powers given them, one being to

remove any person of station and local authority from the commission of the peace, if he enjoyed that dignity. The name of loan given to this tax was a fiction which the most ignorant could not but detect. Many of the common people were impressed to serve in the navy for refusing to pay; and a number of the gentry were imprisoned. The detention of five knights, who sued the Court of King's Bench for their writ of Habeas Corpus, gave rise to a most important question respecting the freedom of English subjects from arbitrary arrest; and out of the discussion which then arose, and the contests respecting the levying of ship-money, &c., came the distinct assertion, and ultimate establishment of the great principle of English liberty. The 13 Car. II. stat. 1, c. 4, provides for a voluntary present to his majesty, with a proviso, however, that no aids of that nature can be but by authority of parliament. The Bill of Rights, in 1688, repeats what Magna Charta declared in 1215, that levying of money for, or to the use of the crown, by pretence of prerogative, without grant of parliament, for longer time, or in any other manner than the same is or shall be granted, is illegal.

(Hallam's *Constitutional History of England*, and Knight's *Popular History of England*.)

BENGALI LANGUAGE. Among the numerous vernacular dialects now spoken in northern India, and apparently descended for the most part from the ancient classical language of the country, the Sanscrit, few possess stronger claims upon the attention of the linguist as well as the politician than the Bengali, the colloquial medium of a population of more than twenty millions, spread over a territory of about 100,000 square miles. The alphabet employed by the natives in writing, and adopted by Europeans in printing books in the Bengali language, is evidently borrowed from the Devanagari, the character peculiarly appropriated to fix the Sanscrit language: both comprise sixteen vowels and diphthongs, and thirty-three consonants. The resemblance in form which the Bengali bears to the Devanagari character is nearly the same as that of the current English handwriting to the form of letters employed in printing. The ground-work of the Bengali language is Sanscrit, with a small addition of words which cannot be traced to that source. But the refined system of grammatical inflexions, which constitute so prominent a characteristic of the Sanscrit language, has in Bengali entirely disappeared; and the want of terminations marking the cases and numbers of the noun, or the persons and tenses of the verb, is supplied by particles and other auxiliary words, often rather clumsily subjoined (hardly ever prefixed) to the mutilated stems of Sanscrit words, and these particles to some extent supply the place of articles; placed after a noun or adjective it is definite, before either it marks it as indefinite. The Bengali has, however, preserved to a very considerable extent the faculty, so conspicuous in Sanscrit, of forming compound words, and recent writers have largely availed themselves of this advantage, especially in treatises on Hindoo law and on philosophical subjects: we allude especially to the Bengali translation of the second book of the 'Mitāksharā' (a Sanscrit law-book of high authority), published by Lakshmi Nārāyana Nyāyālakāra (in 1824, 8vo.), and to that of the 'Nyāyadarsana,' by Kāsinātha Tarkopanchānana.

It does not appear that the Bengali language was ever employed for literary purposes prior to the 16th century. The earliest Bengali work extant is the 'Chaitanya-Charitāmrita,' by Krishnadāsa, a disciple of the Vaishnava fanatic Chaitanya, the founder of a new mode of the worship of Krishna, who lived towards the close of the 15th century. This work, which is almost as much Sanscrit as Bengali, was till within very recent times followed by only a few compositions, the most important of which were the poetical versions, from Sanscrit into Bengali, of the 'Mahābhārata,' by Kāsīdāsa, and of the 'Rāmāyana,' by Kṛitīvāsa; these works are very popular in Bengal, and are frequently recited at the houses of Hindoos during several days, before assemblies of two or three hundred auditors. Khemananda is named as the author of a hymn called 'Manasā-mangala,' which is still recited at the festivals in honour of the goddess Manasā, in the western provinces of Bengal. A treatise on arithmetic, written in verse, is ascribed to Subhancara: this work, and a treatise called 'Gurudakshinā,' appear to have been the only elementary books composed by natives of Bengal for the purposes of education. A new epoch in Bengali literature was begun with the foundation of the college of Fort William near Calcutta, and with the labours of Dr. Carey and his colleagues the Serampore missionaries, to whom, according to the expression of a native author, may be ascribed "the revival of the Bengali language, its improvement, and in fact its establishment as a language." The Bible and various works of modern literature were translated into Bengali, and printed: among others, 'Bunyan's Pilgrim's Progress,' by F. Carey (Serampore, 1821), 'Rasselas,' by Rājā Krishnachandra Roy, and the 'Discourse on the Advantages of Knowledge,' published by the Society for the Diffusion of Useful Knowledge. At the same time various elementary works were printed, partly by the mission press at Serampore, and partly under the superintendence of the Calcutta School-Book Society. An impulse was thus given to the cultivation of the language among Europeans as well as among the natives, and the taste of the latter for reading is attested by the fact that several newspapers in the Bengali language are circulated in Calcutta and its vicinity; the extension of the means of education have been mentioned under BENGAL, in GEOG. DIV. A Dictionary in English and Bengali, translated from Todd's

edition of Johnson's English Dictionary, by Rām Comulsēn (Serampore, 1834, 2 vols, 4to.), is a work which does high honour to the zeal and perseverance, and, as far as we may presume to give an opinion, to the talent and skill of the translator. We are indebted to the author's preface for the greater part of the preceding remarks concerning the literature of the Bengālī language.

From the alterations which have been made in the selection of cadets for the East India Company's service, a knowledge of this language has become highly important. To those who wish to commence the study of the Bengālī language, the following elementary works will be found useful: 'A Grammar of the Bengālī Language,' by the Rājā Rammohun Roy; and 'A Grammar of the Bengalee Language, adapted for Natives and Europeans,' by a Native, Calcutta, 1850; there are also the Dictionary above-mentioned, that of Dr. Carey, and others, including abridgements.

BENI is a form of the plural of the Arabic word *Ebn* or *Ibn*, "a son." It occurs in eastern geography as a component part of many names of families or tribes, as *Beni Temīm*, "the sons of Temīm," that is, the tribe of Temīm, or the Temimides; *Beni Omayyah*, "the sons of Omayyah," that is, the family known in history under the current name of the Ommyades: *Tiah Beni Israel*, "the desert of the sons of Israel," the name of a dreary wilderness towards the north of Mount Sinai.

BENIC ACID ($C_{14}H_{13}O_3HO$). An acid obtained by the saponification of *oil of ben*. It fuses at 169° , and forms salts and an ether.

BENZAMIDE. [BENZOIC GROUP; AMIDES.]

BENZIDAM. [ANILINE.]

BENZIDINE. [PHENYLIC GROUP.]

BENZILE. [BENZOIC GROUP.]

BENZILIC ACID. [BENZOIC GROUP.]

BENZIMIDE, $C_{10}H_9O_2$, *Hydride of Cyanbenzoyl*. This is one of the numerous compounds described by Laurent as the result of the study of hydride of benzoyl, the oil of bitter almonds. It is found in the oil in a crude state. It is crystallisable, and is decomposed by acids into benzoic acid, formic acid, and ammonia.

BENZINE. [BENZOLE]

BENZOATES. [BENZOIC ACID.]

BENZOENE, a name synonymous with *Toluole*. [TOLUOLE.]

BENZOGLYCOLLIC ACID, $C_{18}H_{17}O_7 + HO$. This acid is formed when hippuric acid is exposed to the action of hyponitrous acid. It is crystalline, soluble in alcohol and ether, less soluble in cold water. When heated with acids it is decomposed, yielding benzoic acid and glycollic acid.

BENZOIC ACID ($C_7H_5O_2HO$). This acid, as its name imports, is usually obtained from the resinous substance called gum benzoin or benjamin; it occurs also in some other vegetable bodies, as the balsam of Peru and of Tolu, storax, in the flowers of the *Trifolium melilotus officinalis*, and in the yellow Australian gum obtained from the *Xanthorrhoea hastilis*. It is found also in the urine of the cow, horse, and other herbivorous animals, and also in that of children.

It may be prepared from benzoin either by sublimation or by precipitation; the former method is employed in the London, and the latter in the Berlin Pharmacopœia. The process of sublimation is perfectly simple; the benzoin being subjected to a moderate heat in a proper vessel, the benzoic acid rises in vapour and is condensed in the upper and cool part of it. As thus obtained, it is mixed with a considerable quantity of empyreumatic oil, which gives it both colour and smell; the greater part of this oil is separated by absorption and pressure, and the acid being then resublimed, retains but little, and derives from it an agreeable odour; it is frequently called *flowers of benzoin* or of *benjamin*.

In the Berlin Pharmacopœia four parts of benzoin, reduced to powder, are first digested and then boiled in water, with nine parts of carbonate of soda; the solution of benzoate of soda thus formed is decomposed by sulphuric acid, which, combining with the soda, separates the benzoic acid, the greater part of which is precipitated, owing to its slight solubility.

Benzoic acid may also be obtained by boiling hippuric acid (obtained from cow's urine) with concentrated hydrochloric acid. [HIPPURIC ACID.]

Benzoic acid possesses the following properties: when pure it crystallises in colourless, pearly, elastic needles, which are perfectly inodorous; its taste is rather aromatic and penetrating, than sour; by exposure to the air it undergoes no change; it requires two hundred times its weight of cold, or twelve of boiling water for solution; on cooling, a crystallised mass is obtained, which resembles fat in appearance; alcohol takes it up readily and in large quantity; prismatic crystals are procured by the spontaneous evaporation of the spirit. The aqueous solution acts but feebly upon litmus paper; it combines readily with alkalis, earthy and metallic oxides, forming salts which are called *benzoates*.

Benzoic acid fuses at 248° Fahr., and sublimes at 293° . It boils at 462° . Suddenly heated in the open air it takes fire, and burns with a bright yellow flame. When its aqueous solution is boiled, much benzoic acid passes off with the aqueous vapour. Administered to animals it is transformed into hippuric acid, and is found as such in their urine.

Anhydrous benzoic acid ($\frac{C_{14}H_{13}O_2}{C_{14}H_5O_2} O_2$) is prepared by acting upon

the benzoate of soda with pentachloride or oxychloride of phosphorus. It is formed also when benzoate of soda is heated to 266° Fahr. with chloride of benzoyl, or when chloride of benzoyl is heated over a lamp with neutral oxalate of potash. (Gerhardt, 'Chemie Organique,' vol. iii. p. 207). The most advantageous method for its preparation is with the oxychloride of phosphorus. Oxychloride of phosphorus being placed in a flask, a little more than five times its weight of finely powdered anhydrous benzoate of soda is added in small quantities at a time with repeated agitation. The flask is then heated to 316° Fahr. on a sand bath. The product is then washed with cold water containing a little carbonate of soda which removes the chloride of benzoyl which may have been formed in small quantities. The ultimate reaction is

The anhydrous benzoic acid may be purified by distillation, it melts at 108° Fahr., and boils at about 590° . It dissolves in alcohol and ether, separating from such solutions in oblique prisms. It is quite insoluble in cold water; on boiling with water, it becomes gradually hydrated, being converted into ordinary benzoic acid. It readily unites with the alkalis, on being boiled with their aqueous solutions, giving rise to the corresponding benzoates. With hot aqueous ammonia it forms benzamide [*Benzamide*] and benzoate of ammonia.

Compounds exist of anhydrous benzoic acid with other anhydrous acids. Such are anhydrous acetobenzoic and valerobenzoic acids. They are formed by the action of anhydrous benzoate of soda upon the chlorides of acetyl, valeryl, &c.

These bodies are heavier than, insoluble in, but gradually decomposed by water, as also by distillation *per se* into the constituent anhydrous acids. In a similar manner are formed compounds of anhydrous benzoic acid, with anhydrous cenanthylic, pelargonic, salicylic, cumic, myristic, and cinnamic acids. [ANHYDRIDES.]

Anhydrous nitrobenzoic acid ($\frac{C_{14}H_4(NO_2)_2O_2}{C_{14}H_4(NO_2)_2O_2} O_2$), which contains two molecules of NO_2 in place of two atoms of hydrogen, is obtained by acting upon 8 parts by weight of dry nitrobenzoate of soda with 1 part of oxychloride of phosphorus. The two are heated for some time in a flask at 300° Fahr., until the smell of chloride of nitrobenzoyl disappears. Anhydrous nitrobenzoic acid is thus obtained as a white mass which may be washed with cold water. Anhydrous nitrobenzoic acid is almost insoluble in boiling alcohol and ether; it is soon hydrated on contact with water, being converted into ordinary nitrobenzoic acid. (Gerhardt, 'Ann. de Chem. et de Phys.' xxxvii. 321.)

Benzoic acid combines readily with the alkalis directly, it also decomposes their carbonates, driving out their carbonic acid, and forming in both cases benzoates. From the benzoates of the alkalis the benzoates of the heavy metals may generally be prepared by double decomposition. The latter benzoates (those of the heavy metals), as well as the benzoates of the alkaline earths, may also be obtained by digesting benzoic acid with the corresponding oxides.

Benzoic acid forms two salts with potash. *Neutral benzoate of potash* ($KO C_{14}H_5O_2 + HO$) is best obtained by neutralising a boiling aqueous solution of benzoic acid with carbonate of potash, evaporating on a water bath, to dryness, boiling with alcohol, filtering, evaporating on a water bath, and allowing to stand: the neutral benzoate of potash separates out as the solution cools. The water is given off on exposure to the air. The acid salt of potash ($KOC_{14}H_5O_2 + HOC_{14}H_5O_2$) or *benzoate of potash and water* is often formed in the preparation of anhydrous acetic acid by the action of chloride of benzoyl upon acetate of potash, and remains in the residue from which the anhydrous acetic acid has been distilled. It is less soluble than the preceding neutral salt.

Benzoate of soda ($NaO C_{14}H_5O_2 + ? HO$) is obtained by neutralising benzoic acid with carbonate of soda. As the benzoate of soda is only slightly soluble in alcohol it cannot be purified as the corresponding potash salt. Benzoate of soda is efflorescent, which shows that it contains water of crystallisation.

Neutral benzoate of ammonia can only be prepared by neutralising aqueous solution of benzoic acid with ammonia, and adding ammonia frequently during the evaporation of the solution: in this manner a salt is obtained ($NH_4OC_{14}H_5O_2 + ? HO$) which crystallises in rhombic tables, and is easily soluble in water and alcohol. If no ammonia be added during the evaporation of the neutralised solution, or if such a solution containing the neutral salt be exposed to the air, ammonia is discharged and an acid salt crystallises out which is less soluble in alcohol and water than the neutral salt: its composition is $NH_4OC_{14}H_5O_2HOC_{14}H_5O_2 + ? HO$.

Dry benzoate of ammonia when heated gives off water (a little ammonia) and cyanide of phenyl,

The latter body is also called *benzonitrile*.

Benzoate of lime ($\text{CaO} \cdot \text{C}_6\text{H}_5\text{O}_2 + 4\text{H}_2\text{O}$) is prepared by neutralising benzoic acid with milk of lime, precipitating the slight excess of lime with carbonic acid, warming, filtering, and evaporating. Benzoate of lime crystallises in needles or nuclei, which dissolve in from 20 to 30 parts of cold water. On heating benzoate of lime, a part of the carbon remains behind to form carbonate of lime, the rest is given off as benzole, naphthalene, and other hydrocarbons.

Benzoate of baryta ($\text{BaOC}_6\text{H}_5\text{O}_2 + 2\text{H}_2\text{O}$), and *Benzoate of strontia* ($\text{SrOC}_6\text{H}_5\text{O}_2 + 2\text{H}_2\text{O}$) are very similar in their preparation and properties to the lime salt; they are, however, less soluble than the latter in cold water. They do not effloresce in the air.

Benzoate of magnesia ($\text{MgOC}_6\text{H}_5\text{O}_2 + ?\text{H}_2\text{O}$), prepared like the salts of the alkaline earths, is very soluble in water, and crystallises from its solutions in well-defined efflorescent crystals.

Benzoate of alumina is crystalline and soluble in water, but its exact composition is not known.

The *benzoates of zinc, nickel, cobalt, and protoxide of iron* are soluble and crystallisable. The zinc salt is colourless, that of nickel green, that of cobalt red, and that of protoxide of iron is nearly colourless, but becomes green on exposure to the air. The peroxide of iron forms several compounds with benzoic acid. The *neutral benzoate of iron* dissolves partly in water, leaving a residue of a subsalt. An insoluble *benzoate of peroxide of iron* is also formed by adding benzoate of ammonia to a solution of chloride of iron nearly neutralised by ammonia: the benzoate of iron so formed is said to have the composition, $2\text{Fe}_2\text{O}_3 \cdot 3\text{C}_6\text{H}_5\text{O}_2 + 15\text{H}_2\text{O}$.

Benzoate of manganese ($\text{MnOC}_6\text{H}_5\text{O}_2$) dissolves in 20 parts of cold, and less of hot water; it crystallises from its solutions in transparent needles.

Benzoate of cadmium ($\text{CdO} \cdot \text{C}_6\text{H}_5\text{O}_2 + 2\text{H}_2\text{O}$), prepared by saturating hot aqueous solution of benzoic acid with carbonate of cadmium, filtering and evaporating; crystallises in a mass of brilliant acicular crystals.

Benzoate of copper ($\text{CuOC}_6\text{H}_5\text{O}_2$). When sulphate of copper is treated with a hot solution of benzoate of potash, a number of small light bluish-gray needles of the benzoate of copper are precipitated, which, on recrystallising from warm dilute acetic acid, are obtained as green anhydrous crystals insoluble in alcohol. The products of the destructive distillation of benzoate of copper, are principally benzoic acid, benzole, and benzoate of phenyl.

Mercury forms with benzoic acid two salts, corresponding to the stages of oxidation of the mercury. *Mercuric benzoate* ($\text{HgOC}_6\text{H}_5\text{O}_2 + \text{H}_2\text{O}$) is precipitated as a white crystalline substance on adding benzoate of potash to perchloride of mercury. It is very soluble in hot, but insoluble in cold water. *Mercurous benzoate* ($\text{Hg}_2\text{OC}_6\text{H}_5\text{O}_2$), prepared similarly to the mercuric salt, resembles it in its appearance and solubility in water. It is however turned yellow on exposure to the light; and on boiling, it is decomposed, metallic mercury being precipitated.

Benzoate of silver ($\text{AgOC}_6\text{H}_5\text{O}_2$) is precipitated as a thick white mass by bringing together soluble silver and benzoic salts. It is almost insoluble in cold, but partially soluble in hot water, from which solution it separates on cooling in the form of long crystalline scales.

Benzoate of lead ($\text{PbOC}_6\text{H}_5\text{O}_2 + \text{H}_2\text{O}$) is precipitated as a voluminous crystalline powder, on mixing acetate of lead with benzoate of potash. The water is driven off at about 212°Fahr. , at which temperature the salt melts. Benzoic acid also forms with lead other more basic compounds, the constitution of which is little known.

Benzoic acid combines also with the oxides of the organic radicals, forming with them the corresponding benzoic ethers. The above-described double anhydrous acids, namely, acetobenzoic and valero-benzoic acid ($\text{C}_6\text{H}_5\text{O}_2 \cdot \text{C}_2\text{H}_3\text{O}_2$ and $\text{C}_6\text{H}_5\text{O}_2 \cdot \text{C}_4\text{H}_7\text{O}_2$), may be viewed as benzoates of the oxides of the oxy-radicals, acetyl or ethyl ($\text{C}_2\text{H}_3\text{O}_2$), and valeryl ($\text{C}_4\text{H}_7\text{O}_2$).

Benzoate of methyl ($\text{C}_2\text{H}_5\text{O} \cdot \text{C}_6\text{H}_5\text{O}_2$). To prepare this substance, two parts by weight of benzoic acid are placed in a retort, and a mixture of two parts of monohydrated sulphuric acid with one part of methylic alcohol is added, and the whole distilled until no more benzoate of methyl appears in the distillate. Water is then added to the residue in the retort, and the distillation repeated. It is advantageous that the sulphuric acid and methylic alcohol should be mixed a day or two beforehand, in order that methylosulphuric acid may have been fully formed. The distillate is heated in a water bath, to expel the uncombined methylic alcohol, dried with chloride of calcium, and rectified from oxide of lead, which retains any benzoic and sulphuric acids which have been carried over mechanically, and sulphurous acid which has been formed. Benzoate of methyl is a transparent colourless liquid, of pleasant odour, miscible with ether and alcohol, insoluble in water. Boiling-point 388°Fahr. ; specific gravity, 1.087 at 60° . Vapour density, 4.717.

Benzoate of ethyl—Benzoic ether ($\text{C}_2\text{H}_5\text{O} \cdot \text{C}_6\text{H}_5\text{O}_2$) is formed by digesting for several hours, in a retort connected with an inverted and well-cooled condenser, four parts by weight of ethylic alcohol (89°-90° per cent), two parts of benzoic acid, and one part of fuming hydrochloric acid. After the contents of the retort have stood a day, the alcohol is distilled off from a water bath, and the benzoate of ethyl precipitated by the addition of water to the residue in the retort.

Another method is, to dissolve three parts of benzoic acid in two parts of boiling alcohol, in a retort arranged as before, and to saturate the mixture with gaseous hydrochloric acid, and proceed as before. The product from either mode of preparation is agitated with aqueous carbonate of soda, washed with water, dried with chloride of calcium, and rectified from oxide of lead. Benzoate of ethyl is transparent, colourless, and of agreeable odour. Boiling-point, 415°Fahr. ; specific gravity, 1.055 at 50° ; vapour density, 5.406. Benzoate of ethyl, when taken internally, has an intoxicating action, and is converted in the system into hippuric acid, which appears in the urine.

Benzoate of amyl ($\text{C}_{10}\text{H}_{21}\text{O} \cdot \text{C}_6\text{H}_5\text{O}_2$) is prepared in the same manner as the benzoate of ethyl, amyl alcohol being substituted for the ethylic. It is a yellowish liquid, insoluble in water, but soluble in ether and alcohol. Boiling-point, 502° ; specific gravity, 0.992 at 57° .

Benzoate of phenyl—Benzophenide ($\text{C}_6\text{H}_5\text{O} \cdot \text{C}_6\text{H}_5\text{O}_2$). When carbolic acid is gently heated with chloride of benzoyl until hydrochloric acid ceases to be evolved, the product on cooling solidifies to a crystalline mass containing the benzoate of phenyl.

The compound is obtained pure by solution in a mixture of alcohol and ether, and evaporation; an insoluble oily body which is generally formed, and which is probably a mixture of the benzoate of phenyl with some benzoate of ethyl, being mechanically separated. Benzoate of phenyl possesses the odour of geraniums; it crystallises in rhombs, which melt at 158°Fahr.

All these three organic benzoates are slowly converted by hydrate of potash into benzoate of potash and the corresponding alcohols; and this decomposition is effected more rapidly if alcoholic caustic potash be employed. Anhydrous benzoic acid may also be made to combine directly with the aldehydes, ethylic aldehyde and valeral, by sealing the two together in glass tubes, and heating to 63° . The compounds formed have the composition $\text{C}_6\text{H}_5\text{O}_2 \cdot \text{C}_2\text{H}_3\text{O}_2$ and $\text{C}_6\text{H}_5\text{O}_2 \cdot \text{C}_4\text{H}_7\text{O}_2$.

Benzoic acid unites directly with anhydrous sulphuric acid, forming therewith a copulated acid, *sulphobenzoic acid* ($\text{C}_6\text{H}_5\text{O}_2 \cdot 2\text{SO}_3$). As this acid, however, combines with two atoms of base to form neutral salts, its formula is probably $2\text{HO} \cdot \text{C}_6\text{H}_5\text{O}_2 \cdot 2\text{SO}_3$. The acid is prepared by leading the vapour of anhydrous sulphuric acid into benzoic acid as long as heat is evolved. On treating the transparent mass so obtained with water, the free benzoic acid, being insoluble, is separated. The filtrate is then saturated with carbonate of baryta and filtered, whereby the free sulphuric acid remains behind as insoluble sulphate. Enough hydrochloric acid is then added to the warm filtrate to combine with half the barium present; this converts the soluble neutral sulphobenzoate into an insoluble acid, sulphobenzoate of baryta, which separates out on cooling, and may be purified by recrystallisation. The free acid is obtained from the acid baryta salt by precipitating the baryta exactly with sulphuric acid, filtering and evaporating, until a temperature of 300°Fahr. is reached. On cooling, the sulphobenzoic acid separates out in the crystalline form.

Of the *sulphobenzoates*, the *baryta salts* may be got by evaporating the two solutions described in the above preparation of the free acid, before and after the addition of the hydrochloric acid. The neutral salt is anhydrous ($2\text{BaOC}_6\text{H}_5\text{O}_2 \cdot 2\text{SO}_3$), and exceedingly stable. The acid salt contains three atoms of water of crystallisation. The *acid* and *neutral potash salts* are got from the corresponding baryta compounds, by exact precipitation with sulphate of potash, and filtration. The first is efflorescent, the second deliquescent, in the air. *Neutral sulphobenzoates of lead and silver* are formed by digesting the free acid with the corresponding metallic carbonates. The lead salt contains four, the silver two, atoms of water.

A *sulphobenzoate of ethyl* has been also formed by the action of the chloride of sulphobenzoyl upon alcohol. Its properties have not been much studied.

By acting upon sulphobenzoic acid with pentachloride of phosphorus, a peculiar acid is obtained, which contains an atom of chlorine in place of one of hydrogen; this is *chlorobenzoic acid*, ($\text{HO} \cdot \text{C}_6\text{H}_4\text{ClO}_2$). Its formation is preceded by that of the chloride of chlorbenzoyl ($\text{C}_6\text{H}_4\text{ClO}_2\text{Cl}$), and it is prepared as follows:—One part of sulphobenzoic acid is gently heated in a retort with two parts of pentachloride of phosphorus. The heat is then carried to 338°Fahr. , at which temperature the oxychloride of phosphorus which has been formed passes over. On changing the receiver, and applying a stronger heat, sulphurous acid is disengaged, and the chloride of chlorbenzoyl distils. On agitating this product with water, it is decomposed into hydrochloric acid and chlorobenzoic acid. The latter may be purified by combining it with potash, then boiling with caustic potash, and precipitating by the addition of hydrochloric acid. Chlorobenzoic acid is a colourless solid, which melts at 284°Fahr. and readily sublimes; it is soluble in ether, alcohol, and hot water, but insoluble in cold water. Chlorobenzoic acid may also be formed by boiling benzoic acid with chlorate of potash and hydrochloric acid. Fuming

nitric acid converts chlorobenzoic acid into *nitrochlorobenzoic acid* $\left(\text{HOC}_{14}\text{NO}_2\left\{\text{O}_3\right\}\right)$. Chlorobenzoic acid combines directly with single atoms of the metallic oxides, forming therewith salts of which the potash and soda salts are uncrystallisable; the ammonia salt is decomposed on evaporation. The baryta and lime salts are crystallisable, and both contain three atoms of water. The silver, lead, and copper salts are insoluble, and should therefore be prepared by double decomposition: the first is crystalline, the two others amorphous. Chlorobenzoate of ethyl $\left(\text{C}_4\text{H}_5\text{O}, \text{C}_{14}\text{H}_7\left\{\text{O}_3\right\}\right)$ is a liquid which boils at 473° Fahr.; it is prepared by heating the free acid with alcohol and sulphuric acid, and precipitation with water.

An acid identical in composition with chlorobenzoic acid, when both are in the free state, is prepared by distilling together salicylic acid with pentachloride of phosphorus, and boiling the oily distillate (rectified at 392° - 480° Fahr.) with water. Hydrochloric acid is thereby formed, and a crystalline substance separates out on cooling. This is the new acid. It is purified in the same manner as described for chlorobenzoic acid. The only observable difference between this body and chlorobenzoic acid is in the melting point of the former, 266° , and in the amount of water contained in its salts; the baryta salt being anhydrous, and the lime salt containing only two atoms of water. This acid has consequently been called *parachlorobenzoic acid*. The bromine acid corresponding to chlorobenzoic acid, namely, *bromobenzoic acid* $\left(\text{HOC}_{14}\text{Br}\left\{\text{O}_3\right\}\right)$,

has been prepared by the action of bromine upon benzoic acid in the sunlight, and by the gradual action of bromine vapour upon benzoate of silver. Neither the free acid nor its salts have been much examined. The free acid melts at 212° Fahr., and sublimes (but not without decomposition). It is difficultly soluble in water, easily so in alcohol and ether.

Another substitution product of benzoic acid is the *nitrobenzoic acid* $\left(\text{HOC}_{14}\left(\text{NO}_2\right)\left\{\text{O}_3\right\}\right)$. This acid, which contains an atom of peroxide of nitrogen, NO_2 , in place of one of hydrogen, is a product of the action of nitric acid upon benzoic acid. It is best prepared by mixing two parts of nitrate of potash with one part of benzoic acid, and adding enough strong sulphuric acid to form bisulphate of potash; the mass being constantly stirred during the addition of the sulphuric acid. The mass so obtained is heated until the nitrobenzoic acid melts; it is then poured off from the bisulphate of potash which has been formed, and purified by recrystallisation from boiling water. Nitrobenzoic acid consists of colourless crystals, which sublime with partial decomposition below their melting point, 338° Fahr., giving off suffocating fumes. It is readily soluble in boiling water, difficultly so in cold water. Nitrobenzoic acid decomposes the carbonates of the alkalies and alkaline earths, forming monobasic salts of the general formula $\text{MO}, \text{C}_{14}\text{H}_7\left(\text{NO}_2\right)\left\{\text{O}_3\right\}$. The *potash* and *soda* salts are difficultly crystallisable; the *ammonia* salt, as it exists in cold solutions, is decomposed by evaporation, an acid salt being formed. It is also gradually converted, on digestion, into nitrobenzamide. The *lime*, *strontia*, and *baryta* salts are soluble and crystalline, and contain 2, $2\frac{1}{2}$, and 4 atoms of water respectively. The *manganese* salt is also soluble and crystalline, and contains four atoms of water, as also does the cadmium salt, which is soluble but not crystalline. The *sesqui-salt* of iron $\left(\text{Fe}_2\text{O}_3, 3\text{C}_{14}\left(\text{NO}_2\right)\left\{\text{O}_3\right\}\right)$, and the *zinc*, *silver*, *lead*, and *copper* salts, are insoluble, and are formed by appropriate double decomposition from the ammonia salt. They are all anhydrous excepting the nitrobenzoate of zinc, which contains five atoms of water.

The *nitrobenzoates* of *methyl* and *ethyl* are prepared by dissolving nitrobenzoic acid in the respective boiling alcohols, and saturation with gaseous hydrochloric acid. The hydrochloric acid should be passed through for a long time, and the product allowed to stand for a day. On adding water, the corresponding nitrobenzoate is precipitated. The nitrobenzoate of ethyl $\left(\text{C}_4\text{H}_5\text{OC}_{14}\left(\text{NO}_2\right)\left\{\text{O}_3\right\}\right)$ so obtained is agitated with a warm solution of carbonate of soda, and then washed with cold water. The solid compound is then pressed between blotting-paper, and recrystallised from a mixture of alcohol and ether. The nitrobenzoate of methyl $\left(\text{C}_2\text{H}_5\text{OC}_{14}\left(\text{NO}_2\right)\left\{\text{O}_3\right\}\right)$ is obtained from its alcoholic solution (and the same method may also be employed with the ethyl compound) by evaporation. It separates out as fine needle-shaped crystals. The nitrobenzoate of ethyl melts at 108° Fahr., and boils at 568° . The methyl compound melts at 158° , and boils at 534° . Both nitrobenzoates are readily soluble in ether and alcohol, but insoluble in water. On boiling with hydrated potash, the alcohols are regenerated, and benzoate of potash formed.

By the continued action of nitric acid, assisted by the presence of sulphuric acid, upon benzoic acid, a second atom of hydrogen undergoes replacement by another atom of peroxide of nitrogen, and an acid is formed, having the composition $\text{HOC}_{14}\left(\text{NO}_2\right)_2\left\{\text{O}_3\right\}$: this is *binitro-benzoic*

acid. To prepare it, small quantities of benzoic acid are successively added to a mixture of fuming nitric and monohydrated sulphuric acids. When complete solution has been effected, the product is heated for several hours until it begins to become turbid. It is then allowed to cool, and is mixed with water. The insoluble flocculent portion is washed with water, pressed between blotting-paper, and recrystallised from boiling alcohol, from which it crystallises in bright colourless scales. Binitrobenzoic acid is also soluble in ether, almost insoluble in cold, but slightly soluble in boiling water. Strong nitric and sulphuric acids dissolve binitrobenzoic acid in considerable quantity without decomposition. It is readily fusible, and may be sublimed with care without decomposition. The salts of the alkalies with this acid, being soluble, are prepared by direct neutralisation. The lead and silver compounds are insoluble, and must therefore be formed by double decomposition.

Binitrobenzoate of ethyl $\left(\text{C}_4\text{H}_5\text{O}, \text{C}_{14}\text{H}_7\left(\text{NO}_2\right)_2\left\{\text{O}_3\right\}\right)$ is slowly formed upon boiling binitrobenzoic acid with alcohol. A portion of the binitrobenzoate of ethyl separates from the alcoholic solution in oily drops; the remainder, which is dissolved in the alcohol, is precipitated therefrom, along with uncombined binitrobenzoic acid, on the addition of water. The latter is removed by digestion with ammonia; the product thus purified is then washed with water and dissolved in boiling alcohol. The pure ether separates from the alcoholic solution, on cooling, in the form of long silky needles of a faint yellow colour.

Alcoholic ammonia converts binitrobenzoic acid into *binitrobenzamide* $\left(\text{N}\text{C}_{14}\text{H}_3\left(\text{NO}_2\right)_2\left\{\text{O}_2\right\}\right)$. Caustic potash, when boiled with binitrobenzoate of ethyl, determines the formation of dinitrobenzoate of potash and the separation of alcohol.

A part of the hydrogen of benzoic acid may undergo replacement by chlorine, and another part by NO_2 , and the product still maintain its

acid character. Such is the *nitrochlorobenzoic acid* $\left(\text{HOC}_{14}\text{Cl}\left(\text{NO}_2\right)\left\{\text{O}_3\right\}\right)$. To prepare this acid, chlorobenzoic acid is treated with fuming nitric acid. The product, after standing some hours, is mixed with water, which after some days determines the separation of the new acid, in the form of transparent tabular crystals, which melt at 244° , and may be recrystallised from ether or alcohol, but not from water. The *nitrochlorobenzoates* of *baryta* and *silver* are both monobasic, and contain two equivalents of water. The *silver* salt is crystalline, and tolerably soluble in water; the *baryta* one is amorphous, and more readily soluble.

It is clear that anhydrous benzoic acid, $\text{C}_{14}\text{H}_5\text{O}_2\left\{\text{O}_2\right\}$, may be viewed as the oxide of an oxygen radical $\left(\text{C}_{14}\text{H}_5\text{O}_2\right)$. This radical, which is called *benzoyl*, may, like acetyl and the hydrocarbon radicals, play the part of an atom of hydrogen. By the replacement of a portion of the hydrogen of ammonia by benzoyl, a substance, *benzamide*, $\text{N}\left\{\text{C}_{14}\text{H}_5\text{O}_2\right\}_{\text{H}_2}$ is obtained. [AMIDES.]

BENZOIC ACID, Medical uses of. There is some difference in the qualities of the acid, according to the source whence it is obtained: for medical purposes the acid procured from benzoin by sublimation, and termed "flowers of benzoin," should alone be used.

Sublimed benzoic acid occurs in white, needle-like prisms, which, when in mass, have a flocculent appearance, with a soft, silky lustre. The odour is said to be owing to a little empyreumatic oil; the taste is at first sweetish, but afterwards very pungent; the specific gravity is 0.657. Its acid quality is manifested by reddening turmeric paper; it is scarcely soluble in water, whether warm or cold; it is completely soluble in alcohol: it therefore enters into the composition of the *Tinctura camphoræ composita* of the 'London Pharmacopœia,' and the *Tinctura opii ammoniata* of the 'Edinburgh Pharmacopœia,' two preparations long known under the name of paregoric elixir. The use of these requires care and judgment. [BALSAMS.]

Benzoic acid has been recommended to be inhaled with the vapour of water in consumption and spasmodic asthma. In the former of these diseases it is of no efficacy, and in the latter of very little. Benzoic acid, combined with extract of conium, forms a useful expectorant in the humid asthma of old or feeble persons.

Benzoic acid alone, or in combination with ammonia, is of undoubted value in the treatment of atonic gout. (See Ure in 'Medico-Chirurg. Trans.' vol. xxiv. p. 30; and 'Pharmaceut. Trans.' vol. i. p. 24.)

BENZOIC ALCOHOL. *Hydrate of Toluyll* $\left(\text{C}_{14}\text{H}_7\left\{\text{O}_2\right\}\right)$. This body, which stands to benzoic acid in the same relation as vinic alcohol to acetic acid, is produced by the action of an alcoholic solution of potash upon hydride of benzoyl:—

It is highly probable that the *Taurylic Acid* found by Staedeler in the urine of the horse and cow, and in human urine, is identical with benzoic alcohol. Benzoic alcohol is a colourless oil, heavier than water. It boils at 400° Fahr. Oxidising agents convert it into benzoic acid, just as they convert vinic alcohol into acetic acid.

BENZOIC ETHER. [BENZOIC ACID.]

BENZOIC GROUP. A very numerous family of organic compounds, constituting one of the groups of the benzoic series [BENZOIC SERIES], and containing the radical benzoyl, or its derivatives. In addition to a number of substances, which will be found in their alphabetical position, this group contains the following compounds:—

Benzoine? ($C_{14}H_6O_2$). The name benzoine is given to the solid substance obtained by the action of alcoholic caustic potash upon hydride of benzoyl, or oil of bitter almonds ($C_{14}H_5O_2H$), which contains hydrocyanic acid, or by the action of cyanide of potassium upon the pure hydride of benzoyl. As hydride of benzoyl is most consistently to be viewed as an aldehyde, so benzoine stands probably in the same relation to hydride of benzoyl that metaldehyd does to vinic aldehyd.

$C_{14}H_5O_2H$, hydride of benzoyl; $C_4H_5O_2H$, hydride of ethyl, or aldehyd.
 $2(C_{14}H_5O_2H)$ benzoine; $2(C_4H_5O_2H)$ metaldehyd.

If the crude oil of bitter almonds contains a sufficient quantity of hydrocyanic acid, it is quickly converted into a mass of crystalline benzoine on being mixed with a solution of caustic potash in alcohol; and from this mass the pure benzoine is obtained by repeated crystallisation from alcohol. If the oil of bitter almonds is too pure for this, instead of caustic potash an alcoholic solution of cyanide of potassium is employed, and the same process of purification adopted. The nature of the action of the cyanogen in polymerising the hydride of benzoyl is not understood. Benzoine melts at 248° Fahr., and distils at a higher temperature without decomposition. It is insoluble in cold, slightly soluble in hot water,—difficultly soluble in cold, readily soluble in boiling alcohol. Benzoine is re-converted into hydride of benzoyl on being passed through a red-hot tube. On heating benzoine in dry chlorine two atoms of hydrogen are removed in combination with chlorine, and benzile is formed.

The same elimination of hydrogen and formation of benzile is effected by gently heating the benzoine with fuming nitric acid: Fused hydrate of potash determines the formation of benzoate of potash; hydrogen being liberated—

while alcoholic caustic potash on boiling, converts benzoine into *benzilic acid*, which unites with the potash, hydrogen, as before, being set at liberty—

On bringing benzoine in contact with the chlorides of the oxygen radicals benzoyl or othyl, hydrochloric acid is evolved, and the place of the hydrogen, which is derived from the benzoine, is occupied by the oxygen radical employed. These products which are solid crystalline bodies, are freed from hydrochloric acid by being heated on a water-bath and recrystallised from alcohol.

Benzoyl ($C_{14}H_5O_2$). This oxygenous radical of the benzoyl series, which stands in the same relation to benzoic acid that othyl ($C_4H_3O_2$) does to acetic acid, has never yet been obtained in the free state. For benzile [BENZOINE], although having the same composition as benzoyl, and like all hitherto isolated organic radicals having the double atomic weight of the same radical when in combination, yet has properties so different from those which we should expect from the free radical, that it must be viewed as a body merely isomeric with benzoyl. The compounds of benzoyl are of great historical interest, inasmuch as their study first established the possibility of a group of elements containing oxygen, playing the part of a compound radical, that is, of an element.

The *oxide of benzoyl* ($C_{14}H_5O_2, O_2$), or anhydrous benzoic acid. [BENZOIC ACID; ANHYDRIDES.]

Chloride of Benzoyl ($C_{14}H_5O_2 Cl$), is formed directly from the hydride by passing dry chlorine into the latter, and warming as long as hydrochloric acid is evolved, $C_{14}H_5O_2 H + 2Cl = C_{14}H_5O_2 Cl + HCl$. A better way consists in gently heating in a retort 3 parts by weight of previously fused and coarsely pounded benzoate of soda with 1 part of oxychloride of phosphorus, $3(NaO C_{14}H_5O_2) + PO_2 Cl_3 = 3(C_{14}H_5O_2 Cl) + 3NaO PO_3$, and rectifying the distillate at 385° . Chloride of benzoyl is a colourless liquid of most penetrating odour and burning taste. Specific gravity, 1.196; boiling point, 385° ; vapour density, 4.987. It is converted gradually by cold, and quickly by boiling water into benzoic acid (benzoate of water), and hydrochloric acid. With alcohol the action is similar but more energetic, benzoate of ethyl being formed.

The chloride of bichlorobenzoyl, a body which stands in the same relation to benzoyl as chloroform (C_3HCl_3) does to formyl (C_2HO_2), and which may be called *chlorobenz* ($C_{14}H_5Cl_2 Cl$) is formed by heating equivalent quantities of chloride of benzoyl and pentachloride of phosphorus at 392° Fahr. in a sealed glass tube for several days. The tube is then opened and the volatile portions expelled by a temperature of

230° Fahr. The residue, after agitation with caustic potash, washing with water, solution in alcohol and precipitation by water, constitutes the pure chlorobenz, which is a yellowish transparent liquid, soluble in ether and alcohol, but insoluble in water. It is not volatile without decomposition. The body just described is the chloride of benzoyl, in which the oxygen is replaced by chlorine. A body has been formed also by a replacement of a part of the *hydrogen* of the radical in chloride of benzoyl by chlorine. This substance results from the action of pentachloride of phosphorus upon chlorobenzoic acid [BENZOIC ACID]. On distilling the two together, and rectifying the distillate at 437° , a colourless transparent liquid is obtained, boiling at the above temperature, and soluble in alcohol and ether. Its composition is $C_{14}H_4O_2Cl$, being the *chloride of chlorobenzoyl*. This substance dissolves in aqueous ammonia, the solution depositing yellow needles of *chlorobenzamine* $C_{14}H_4O_2H_2N$.

A body ideotypic with the chloride of chlorobenzoyl is the *chloride of nitrobenzoyl* ($C_{14}H_4NO_2Cl$) prepared by the action of pentachloride of phosphorus upon nitrobenzoic acid [BENZOIC ACID]. The distillate produced by heating together nitrobenzoic acid and pentachloride of phosphorus is rectified, the latter portion being free from the oxychloride of phosphorus which is a by-product of the reaction, consists of the chloride of nitrobenzoyl, which is washed with water, dried over chloride of calcium and distilled. It boils at 509° . Chloride of nitrobenzoyl gives a series of compounds precisely analogous to those derived from chloride of benzoyl.

Bromide of benzoyl ($C_{14}H_5O_2Br$). If hydride of benzoyl be mixed with an excess of bromine, heat is evolved, hydrobromic acid liberated, and bromide of benzoyl formed. On heating the product, the hydrobromic acid is expelled along with the excess of bromine, and a half crystalline mass is obtained of pure bromide of benzoyl: a body of an odour similar to, but feebler than, that of the chloride. It is insoluble in, but slightly decomposed by, water; and soluble without decomposition in ether and alcohol.

Iodide of benzoyl ($C_{14}H_5O_2I$) is formed by warming iodide of potassium with chloride of benzoyl. When pure, iodide of benzoyl is colourless; it readily decomposes on heating, iodine being liberated. Its behaviour to water and solvents is the same as that of the bromide.

Cyanide of benzoyl ($C_{14}H_5O_2 Cy$). Is obtained as a colourless liquid on rectifying the product produced by the distillation of equal equivalents of chloride of benzoyl and cyanide of mercury. On standing, the liquid solidifies; it may then be washed with water to remove the chloride of mercury, and pressed between bibulous paper. Cyanide of benzoyl melts at 88° Fahr., and boils at 405° Fahr. It is slowly decomposed by water, readily by the alkalies; in the latter case, benzoates and cyanides are found. Nascent hydrogen converts it into hydride of benzoyl and benzoine.

Sulphide of benzoyl ($C_{14}H_5O_2 S$). Is a soft crystalline yellowish white body, obtained by distilling chloride of benzoyl with sulphide of lead. It is stable in its nature, and its properties have been little studied.

Cyanide of sulphobenzoyl, improperly called sulphocyanide of benzoyl, a body having the composition $C_{14}H_5S_2 Cy$, is obtained by mixing ammonia, bisulphide of carbon, and hydride of benzoyl, and pressing out the crystals which form in the lower of the two layers of the mixture. On washing the crystals with ether, pure cyanide of sulphobenzoyl is obtained. The reaction is as follows: $C_{14}H_5O_2 H + 3NH_3 + 2(CS_2) = C_{14}H_5S_2 Cy + 2NH_4 S + 2HO$. The cyanide of sulphobenzoyl is insoluble in water, but somewhat soluble in alcohol and ether. The products of decomposition are little understood.

Although benzoyl has not been obtained in combination with the metals directly, yet a compound of it with an organic radical, namely, phenyl, is known. This body, *Benzoyl-phenyl*, also called *Benzone* or *Benzophenone*, $C_{14}H_5O_2 C_{12}H_5$ is the acetone of benzoic acid. It is prepared by the destructive distillation of benzoate of lime in presence of about $\frac{1}{10}$ th of its weight of quicklime. The process is best conducted in an iron mercury bottle. Besides benzone the distillate contains, benzole, hydride of benzoyl, and other products; that portion of the distillate is collected which on rectification passes over between 599 and 617° . This portion solidifies on cooling, and is purified by repeated crystallisation from a mixture of alcohol and ether. Benzone melts at 115° Fahr., and boils at 599° Fahr. It is insoluble in water, soluble in strong sulphuric and nitric acids without change. If, however, fuming nitric acid be employed, the nitric acid eliminates two atoms of hydrogen and *binitro-benzone* results. It is most probable that of the two atoms of hydrogen removed, the one belonged to the phenyl, the other to the benzoyl, and that the rational formula of binitro-benzone is

It is prepared by warming benzone with fuming nitric acid, and dissolving the semi-solid product (after washing) in ether. The binitrobenzone crystallises from the ethereal solution as a yellowish white crystalline powder.

Benzonitril. [PHENYL, CYANIDE OF.]

The compounds of benzoyl formed upon the ammonia type are very numerous. Those compound ammonias which contain benzoyl in place of hydrogen, do not combine so readily with the hydracids to form

corresponding salts of the compound ammoniums, as is the case when the replacing organic radical contains no oxygen.

Benzamide or *benzamine* ($\text{N}^{\text{C}_{14}\text{H}_5\text{O}_2}$), is best prepared by pounding carbonate of ammonia of commerce in a mortar, and mixing it with chloride of benzoyl. If the carbonate be employed in excess, the product gently warmed to complete the reaction, and the chloride of ammonium extracted by water, benzamine is obtained, which may be further purified by solution in boiling water or alcohol. Benzamine is a colourless solid crystalline body, which melts at 239° , and distils at a higher temperature without alteration.

The *hydrochlorate of benzamine*, or *chloride of benzammonium* ($\text{N}^{\text{C}_{14}\text{H}_5\text{O}_2\text{Cl}}$), is formed on dissolving, by the aid of heat, benzamine in strong hydrochloric acid. On allowing the solution to cool, the chloride of benzammonium crystallises out in long prisms. This compound gives up its hydrochloric acid even on exposure to the air.

On mixing bromine with benzamine and allowing the mixture to stand for some days in a cool place, crystals are formed of a compound resulting from the union of bromo-benzamine with hydrobromic acid

($\text{N}^{\text{C}_{14}\text{H}_4\text{O}_2\text{Br}}$). This substance is the *bromide of bromobenzammonium*.

Both ammonia and water decompose this substance, and give rise to benzamine.

Mercury benzamine.—Aqueous solution of benzamine dissolves oxide of mercury (HgO): the oxygen of which unites with and removes one of the equivalents of hydrogen in the benzamine, while the mercury takes the place of the hydrogen so extracted, forming *mercury benzamine*

($\text{N}^{\text{C}_{14}\text{H}_4\text{O}_2\text{Hg}}$), which crystallises out of a not too dilute solution. The mercury benzamine on being dissolved in hot alcohol, filtered, and allowed to cool, forms brilliant white scales.

Phenyl benzamine (benzaniline) ($\text{N}^{\text{C}_{14}\text{H}_5\text{O}_2}$), is formed on mixing chloride of benzoyl with phenylamine (aniline). The hydrochloric acid which is formed does not unite with the compound ammonia, but with the excess of phenylamine. The chloride of phenylammonium so formed is removed by boiling the product of the reaction with water, and the phenylbenzamine is recrystallised from boiling alcohol, from which it separates in brilliant scales.

By warming phenylbenzamine with chloride of benzoyl, the remaining equivalent of hydrogen in the phenylbenzamine is removed as hydrochloric acid, by the chlorine of the chloride of benzoyl, and its place is taken by the benzoyl of the latter body. A compound ammonia is thus formed, containing two equivalents of benzoyl and one of phenyl, and being therefore *Phenylbibenzamine* ($\text{N}^{\text{C}_{14}\text{H}_5\text{O}_2\text{C}_{14}\text{H}_5\text{O}_2}$). The product obtained by this reaction, which becomes solid on cooling, is digested with a solution of carbonate of soda, to remove the excess of chloride of benzoyl and free hydrochloric acid, and then recrystallised from boiling strong alcohol. So prepared it forms bright acicular prisms.

The preparation and properties of the following compound ammonias are so similar to those of the above bodies as to require no special description.

Nitrocumylbenzamine ($\text{N}^{\text{C}_{14}\text{H}_5\text{O}_2\text{NO}_4}$), by the action of chloride of benzoyl ($\text{C}_{14}\text{H}_5\text{O}_2\text{Cl}$) upon nitrocumylamine ($\text{N}^{\text{C}_{15}\text{H}_{10}\text{NO}_4}$). [CUMYL.]

Methylnitrophenylbenzamine ($\text{N}^{\text{C}_{14}\text{H}_5\text{O}_2\text{NO}_4}$), by the action of chloride of benzoyl ($\text{C}_{14}\text{H}_5\text{O}_2\text{Cl}$) upon $\text{N}^{\text{C}_{14}\text{H}_6\text{NO}_4}$ (methylnitrophenydine). [PHENYL.]

Nitrobenzoyl, like benzoyl, may replace an equivalent of hydrogen in ammonia, giving rise to *nitrobenzamine* ($\text{N}^{\text{C}_{14}\text{H}_4\text{O}_2\text{NO}_4}$). The best

method of preparing this substance is to dissolve nitrobenzoate of ethyl $\text{C}_2\text{H}_5\text{O} \text{C}_{14}\text{H}_3\text{NO}_4$ [BENZOIC ACID], in alcohol, and to add ammonia in aqueous solution until the ether just begins to be precipitated. The mixture is placed in a stoppered bottle, in a warm place, and allowed to stand until a drop of it no longer gives a turbidity on falling into water. The product is then evaporated on a water bath, and the crystalline mass obtained, dissolved, and recrystallised from a mixture of alcohol and ether. It follows from the manner of the formation of nitrobenzamine that ethylamine, or ether, must accompany its synthesis. Whichever of these is formed, it is driven off from the water-bath. Nitrobenzamine melts below 212° Fahr.

Sulphobenzamine is ammonia containing an equivalent of benzoyl in which the oxygen is replaced by sulphur ($\text{N}^{\text{C}_{14}\text{H}_5\text{S}_2}$). It is formed by dissolving cyanide of phenyl in alcohol, adding a little ammonia and saturating with sulphuretted hydrogen. The liquid changes colour, and after standing some hours gives on evaporation a yellow flocculent precipitate which dissolves in boiling water, and deposits yellow silky needles of sulphobenzamine.

Cyanide of Phenyl.

Sulphobenzamine.

In addition to these compounds, the following bodies also belong to the benzoic group:

Benzamic acid	$\text{C}_{14}\text{H}_6\text{NO}_3, \text{HO}.$	Benzilam	$\text{C}_{26}\text{H}_{18}\text{N}_2$
Benzosulphophenyl- limide	$\text{C}_{12}\text{H}_5, 2, \text{SO}_2$ $\text{C}_{14}\text{H}_5\text{O}_2$ H	Benzilimide	$\text{C}_{26}\text{H}_{22}\text{N}_2\text{O}_4$
		Benzonitranside	$\text{C}_{24}\text{H}_{12}\text{N}_2\text{O}_8$
		Benzostilbine	$\text{C}_{62}\text{H}_{22}\text{O}_4$

For a description of these bodies, and for that of other compounds of the benzoic group, the reader is referred to Gerhardt's 'Traité de Chimie Organique,' tome iii.

BENZOIC SERIES. This series of organic compounds, one of the most numerously represented in organic chemistry, contains, according to Gerhardt's system of classification, the following eight groups, which see:

- | | | |
|--------------------|---------------------|----------------------|
| 1. Phenyl Group. | 4. Salicylic Group. | 7. Naphthalic Group. |
| 2. Quinonic Group. | 5. Anisic Group. | 8. Indigotic Group. |
| 3. Benzoic Group. | 6. Cinnamic Group. | |

BENZOICIN. [GLYCERIN.]

BENZOIN or **BENJAMIN**, a resinous substance, commonly but improperly termed a gum. It is extracted from the *Styrax benzoin*, which grows in Sumatra, by making incisions in the trunk. It hardens very quickly, and is imported in the state of brittle masses, which when fractured present a mixture of white, brown, and red grains, frequently as large as an almond. The fracture of benzoin is conchoidal, and the lustre is greasy; its specific gravity is from 1.063 to 1.092. Its smell is agreeable, resembling that of vanilla. It melts at a moderate heat, and yields benzoic acid, of which it contains about eighteen per cent.

According to the analysis of Unverdorben, benzoin contains, besides benzoic acid and a little volatile oil, three different resins. If benzoin be reduced to fine powder, and boiled in an excess of a solution of carbonate of potash, the benzoic acid and a resin are dissolved, which may be precipitated together by hydrochloric acid; when the precipitate is boiled in water, the acid and a little extractive matter are dissolved, and the resin is left, amounting to about 0.03 of that of the benzoin. This resin is of a deep brown colour; it is soluble in concentrated alcohol, but slightly so in ether and volatile oils, and insoluble in the oil of petroleum. This resin is a feeble negative electric; it does not decompose acetate of copper, but precipitates acetate of lead; carbonate of potash dissolves it but slowly. The compound of this resin with potash is soluble in anhydrous alcohol, but neither in ether nor in oil of turpentine. The aqueous solution is precipitated by chloride of ammonium. The greater part of benzoin is insoluble in solution of carbonate of potash, and it leaves a bright brown residue; from this, ether extracts one resin and leaves another. When the ether is evaporated, the resin dissolved in it remains. This latter resin is very soluble in alcohol and in oil of caraway, but not in oil of petroleum. It does not decompose acetate of copper; it dissolves readily in potash, and is not precipitated from solution by excess of it. Ammonia does not dissolve it; its compounds with earthy and metallic oxides are insoluble in ether.

The resin, which is insoluble in carbonate of potash, and remains unacted upon by ether, is brownish. It is soluble in alcohol, but not in the volatile oils nor ammonia. Potash dissolves it readily, but a great excess of the alkali precipitates the compound which is formed. This and the former resin, when precipitated by an acid from solution in potash, and exposed to the air while moist, are converted into the first resin, or that which is dissolved by carbonate of potash and alcohol. If the two last resins be subjected to dry distillation, they yield at first a volatile oil, which is very slightly empyreumatic, and which, like the oil of bitter almonds, is converted by the action of the air into benzoic acid.

Benzoin is employed in the preparation of benzoic acid; it is also used by perfumers.

BENZOIN, Medical uses of. The benzoin of commerce, sometimes called *Asa dulcis*, and vulgarly termed *Benjamin*, is obtained solely from the *Lithocarpus benzoin*, a tree growing in Sumatra (see Marsden's 'Sumatra,' i. 233), Borneo, Java, &c., from which it flows spontaneously in small quantity, but is obtained in greater abundance by making incisions in the stem beneath where the branches are given off, as soon as the tree has attained the age of five or six years. These incisions are repeated every year for about twelve years, when the tree becomes exhausted; each tree yields annually about three pounds. When it first flows from the tree it is soft, but gradually hardens by exposure to the air. The finest kind, which is whiter, and often in grains, flows from the youngest trees; this is called *Benzoe amygdaloides*. The

spontaneous produce of the tree during the first three years, is termed *head benzoin*; that obtained subsequently, *belly benzoin*; and at the end of ten or twelve years, the tree is cut down, the wood split up, and the scrapings collected and termed *foot benzoin*. These different sorts are of the relative value of 105, 45, 18. The benzoin which is met with in commerce is generally in cakes or fragments of different sizes, of a yellowish or fawn colour, covered with a whitish powder, intermixed with pieces of wood or leaves. When broken it exhibits a vitreous fracture, presenting portions of an almond-like shape, which are whiter than the surrounding portions, transparent, and friable. The more of these white pieces that occur in any specimen, the more it is esteemed; from exposure to the air they assume a yellowish hue. An inferior kind, called *benzoe in sortis*, is grayish brown, of a dull aspect, not transparent, with many portions of wood and bark intermixed with it. But the finest sorts in the European market are got from Siam; the produce, perhaps, according to the conjecture of Dr. Royle, of *Styrax Finlaysonianum*. "It occurs in tears, in irregular lumps, and in cubical blocks; but unlike the Sumatra sort, it never comes over enveloped in calico."—Pereira.

Benzoin is of the specific gravity of 1.063, is friable and easily powdered, during which process it causes sneezing, has an agreeable balsamic odour, and tastes at first sweetish, afterwards balsamic and stimulating. It melts at a moderate degree of heat, and evolves a white smoke and pleasant odour. The fumes which arise consist of benzoic acid, which may be easily condensed in a white flocculent mass, called flowers of benzoin. The odour is attributed by Dr. Thomson to the presence of a volatile oil, which accompanies the acid.

Benzoin is entirely soluble in alcohol and ether, but insoluble in fixed or volatile oils. Its alcoholic solution added to water becomes of a milky appearance.

Stolze analysed the white and brown kinds, and found them to consist of—

	White Benzoin, 100 parts.	Brown Benzoin, 100 parts.
Yellow resin, soluble in ether	79.83	8.80
Brown resin, insoluble in ether	0.25	69.73
Benzoic acid	19.80	19.70
Extractive	0.00	0.15
Impurities	0.00	1.15
Moisture and loss	0.12	0.17
A trace of volatile oil.		

Bucholz, John, and Kopp have analysed benzoin, but none obtained more than 14 per cent. of benzoic acid; the two former only 12. Wackenroder got only 9 per cent. of benzoic acid from Siam benzoin. 'Pharmac. Central-Blatt,' fur. 1843, p. 336.

In its action on the system, benzoin resembles the other balsamic resins; being stimulant and exciting, as well as improving the quality of the secretions of the mucous membrane of the lungs. It was formerly employed as an expectorant in chronic catarrh and in asthma; and it may occasionally be serviceable when, from deficiency of nervous energy, expectoration is difficult, and an accumulation of mucus takes place in the lungs. It cannot fail, however, to prove hurtful if such accumulation arises from difficult circulation through the lungs, connected with organic disease of the heart, which is frequently the source of the spasmodic symptoms called asthmatic. It has also been recommended in cases of imperfect development of cutaneous eruptions, but it cannot be relied on in such cases.

In the present day it is chiefly employed to yield benzoic acid, and as an ingredient in pastilles, or to burn in censers in Roman Catholic churches. It enters into the composition of the *Tinctura benzoini composita*, the use of which is mostly confined to old ulcers; its application to recent wounds is very improper. [BALSAMS.] A solution of benzoin in alcohol, added to twenty parts of rose-water, forms the cosmetic called *Virgin's milk*.

BENZOINAM, $C_{10}H_8N_2O_2$. When a mixture of ammonia, alcohol, and benzoin is left in a closed vessel for some months, several new products are formed, amongst which is *Benzoinam*. It occurs in the form of small white needle-shaped crystals. It dissolves in acids, and is precipitated by alkalis.

BENZOINAMIDE = **HYDROBENZONAMIDE** ($C_{10}H_8N_2O$), is formed by exposing a mixture of benzoin and ammonia. It is a white, tasteless powder, and volatilises without decomposition.

BENZOLACTIC ACID. [LACTIC ACID.]

BENZOLE ($C_{12}H_6$), or *hydride of phenyl* ($C_{12}H_5H$), in the impure state in which it occurs in commerce also called *benzine*, *benzoline*, and *benzine collas*, is a product of very frequent occurrence in the destructive distillation of many substances rich in carbon, such as the fats, fatty acids, coals, alcohol, &c. Benzole is best prepared when wanted in small quantities by heating benzoic acid with three times its weight of slaked lime. The distillate is separated from the water, agitated with potash, and rectified. Benzole also occurs in the liquid which accumulates in the condensers of coal-gas works. The more volatile portion of this liquid is re-distilled, the still being so arranged that the worm is heated to 212° Fahr., and the portions which condense at this temperature run back into the retort. On the second rectification, the worm is only heated to 176° Fahr., and the distillation is discontinued as soon as the contents of the retort reach 194°. The distillate so obtained is treated with dilute nitric and then with

strong sulphuric acid, and submitted to a cold of 11° Fahr., at which temperature the benzole solidifies, and may be freed from the non-solidifying hydrocarbons by pressure.

Benzole is a colourless limpid liquid of agreeable odour. Specific gravity 0.9 at 32° Fahr., and 0.85 at 59° Fahr. Boiling point, 176° to 178° Fahr. Vapour density, 2.752. Point of congelation, 32°; point of liquefaction, 43° Fahr. Benzole is insoluble in water, but soluble in alcohol, ether, and acetone. It is a solvent for sulphur, phosphorus, and iodine to a small extent. It readily dissolves the fats, camphor, wax, caoutchouc, and gutta percha; the resins are dissolved by it with difficulty. Of the alkaloids, the four—quinine, morphine, strychnine, and cinchonine—are dissolved in the above order in respect to quantity; the last, cinchonine, being insoluble. Benzole, by itself, burns with a white but smoky flame, owing to the large quantity of carbon which it contains. Since however alcohol and benzole have nearly the same boiling point, a mixture of the two may be made to give a bright yet smokeless flame (1 vol. of benzole with 2 vols. of spirits of wine at 85 per cent. is a good proportion for this purpose). The illuminating power of ordinary coal-gas may be also much increased by passing it, previous to ignition, through benzole.

One, two, or three atoms of hydrogen in benzole may be replaced by bromine, the substitution products being *mono*-, *bi*-, and *tri*-brombenzole respectively. *Monobrombenzole*, $C_{12}H_5Br$, or the *hydride of monobromphenyl*, is obtained by conducting the vapour of bromine into a flask in which some benzole is heated to ebullition. As soon as two equivalents of bromine have been added, the contents of the flask are washed with aqueous potash, dried, and distilled. Monobrombenzole is a colourless liquid, which boils at 302° Fahr., and whose vapour density is 5.63. Fuming nitric acid converts it into *mono-bromnitrobenzole*,

$C_{12}H_4BrNO_2$, a solid volatile body, which melts at 194°. On leaving monobrombenzole in contact with bromine, hydrobromic acid continues to be evolved, and *bibrombenzole*, $C_{12}H_3Br_2$, separates out in large crystals, which are purified by solution in ether and spontaneous evaporation. Bibrombenzole melts at 192°, and boils at 426° Fahr.

If the bibrombenzole be boiled with alcoholic caustic potash, and the product precipitated with water and dissolved in ether, a solution is obtained from which *tribrombenzole*, $C_{12}H_2Br_3$, separates out as fusible, sublimable needles, soluble in alcohol and ether. The above compound may also be directly obtained, in combination with hydrobromic acid, by submitting benzole to the action of bromine in the direct sun-light.

Its formula is $C_{12}H_2Br_3 + 3HBr$. It is very insoluble in alcohol, ether, and water, not volatile without decomposition. Caustic lime converts it into tribrombenzole.

A similar chlorine compound, $C_{12}H_2Cl_3$, the *terhydrochlorate of trichlorbenzole*, is formed when chlorine is passed into benzole in the direct sun-light. This body, like the preceding, is a solid crystalline one, which may be purified by resolution in alcohol. It melts at 275° Fahr., and boils at 576°. On digestion with alcoholic caustic potash it is converted into *trichlorbenzole*, $C_{12}HCl_3$, which is a colourless oil, of the specific gravity 1.457 at 44.6. It boils at 410° Fahr., and its vapour density is 6.37. The same substance is also obtained by the action of caustic lime or baryta upon chlorbenzole.

One or two atoms of hydrogen of benzole may also be replaced by the group NO_2 , the resulting bodies being the *nitrobenzole*, $C_{12}H_5NO_2$, and *binitrobenzole*, or *dinitrobenzole*, $C_{12}H_3(NO_2)_2$, respectively. Nitrobenzole is prepared by gradually adding benzole to warm fuming nitric acid. On allowing the mixture to cool, the nitro-benzole separates out as an oil, which, after washing with water, is dried and rectified. Specific gravity, 1.209 at 59°. Boiling point, 427°. Vapour density, 4.40. It solidifies at 37.4. It is insoluble in water, soluble in nitric and sulphuric acids, as also in alcohol and ether. On account of its odour closely resembling that of oil of bitter almonds, and on account of its greater cheapness, it is used in perfumery as a substitute for the latter substance.

Dinitrobenzole is best prepared by dropping benzole into a hot mixture of equal parts of fuming nitric acid and oil of vitriol, allowing the mixture to boil for a few minutes, and then washing the crystals, which separate out on cooling in water, and recrystallising from alcohol. Dinitrobenzole crystallises in long needles, which melt at 212°, and are insoluble in water, but easily soluble in alcohol.

As benzole properly belongs to the phenyl group, the numerous derivations to which it and its nitro-substitution products give rise will be described under the head **PHENYL**.

BENZOLE LIGHT. [LIGHTS, ARTIFICIAL.]

BENZOLINE. [AMARINE.]

BENZOLONE, ($C_{11}H_8O$)? When *Hydrobenzamide* ($C_{12}H_{10}N_2$) is heated with potash till it becomes blackish-brown, this compound is formed. The mass, when washed with water, yields benzolone in the

form of small crystals. It gives a bright red colour when acted on by sulphuric acid.

BENZOPELARGONIC ACID ($C_{15}H_{17}O_3$, $C_{14}H_{15}O_3$), a composite anhydrous acid. [ANHYDRIDES.]

BENZOPHENONE. [BENZOIC GROUP.]

BENZOSALICYLIC ACID ($C_{14}H_9O_3$, $C_{14}H_9O_5$). [ANHYDRIDES.]

BENZOVALERIC ACID ($C_{14}H_9O_3$, $C_{10}H_9O_3$). [ANHYDRIDES.]

BENZOYL, HYDRIDE OF ($C_{14}H_9O_2H$), is the aldehyd of benzoic acid, and occurs in commerce as the oil of bitter almonds. The kernels of the fruits of the *Rosaceae* and the allied families, contain amygdalin, together with emulsin. The latter substance in the presence of water acts as a kind of ferment upon the amygdalin, and converts it into the crude oil of bitter almonds. At the same time hydrocyanic acid is formed, which remains dissolved in the hydride of benzoyl. The best method of purifying the commercial oil consists in agitating it with a mixed solution of a ferrous and ferric salt in the presence of an alkali. The cyanogen is thereby converted into prussian blue, and remains behind on distillation. Pure hydride of benzoyl is a colourless highly refractive liquid of aromatic smell and burning taste. Its specific gravity is 1.05 at 58.3 Fahr., boiling point 354°. It is soluble in 30 parts of water, and in all proportions in ether and alcohol. Ignited in the air it burns with a smoky flame. In the bodies of animals it is converted into hippuric acid.

Like all other aldehyds, hydride of benzoyl combines with the double sulphites of the alkalis. The bisulphite of ammonia compound has not been obtained in the pure state. The potash compound crystallises out on agitating the hydride of benzoyl with a solution of bisulphite of potash (of 1.25 sp. gr.). To purify this compound it is strongly pressed between bibulous paper, and recrystallised from boiling alcohol. The corresponding soda salt is prepared in a similar manner; its formula is $C_{14}H_9O_2NaO_2SO_2 + 2HO$. The salts of both potash and soda are readily soluble in water, and are easily decomposed by alkalis and dilute acids; in the former case monobasic sulphites being formed, in the latter alkali salts of the acid employed, sulphurous acid being liberated. In both cases the hydride of benzoyl is separated in the free state. The formation and decomposition of the alkali sulphites of hydride of benzoyl may be advantageously employed to purify the latter body completely.

Hydride of benzoyl quickly oxidises on exposure to the air, being converted into benzoic acid. This is especially the case in the presence of the alkalies which unite with and remove the acid as it is formed. In removing a portion of the oxygen from a confined portion of air, hydride of benzoyl converts the remainder into ozone. Nitric acid, or nitrate of potash, in the presence of strong sulphuric acid, converts

hydride of benzoyl into the *hydride of nitro-benzoyl* ($C_{14}H_9NO_2H$) which is molecularly symmetrical with the hydride. To prepare the hydride of nitrobenzoyl, one part by volume of hydride of benzoyl is agitated with 15 to 20 parts of a mixture of one part of fuming nitric acid and two parts monohydrated sulphuric acid. The heat evolved must be moderated. After complete mixture has been effected, three to four volumes of water are added which precipitate the nitro-compound as an oily liquid; this solidifies after standing a few days, and may be then purified by recrystallisation from boiling dilute alcohol. Hydride of nitrobenzoyl is a colourless solid of feeble odour; it melts at 115°, and is soluble in ether and alcohol. It is not volatile when heated alone, but in a stream of gas (hydrogen, nitrogen, carbonic acid) it may be distilled without residue. Like the hydride of benzoyl, the hydride of nitrobenzoyl combines directly with the bisulphites of the alkalis to form solid compounds, which are soluble in water and alcohol, and give up the organic hydride when warmed with dilute acids or alkalis. The alkali bisulphite salts of the hydride of nitro-benzoyl are less soluble than the corresponding combinations with the hydride of benzoyl; the soda salt contains eleven equivalents of water. [AMYGDALUS.]

BERBERINE ($C_{15}H_{19}NO_{10}$)? an alkaloid little known, found in the *Berberis vulgaris*, and in the root of the *Cocculus palmatus*. It crystallises in yellow silky needles.

BERGAMOT, ESSENCE OF, an essential oil, obtained both by pressure and distillation from the rind of the bergamot, the ripe fruit of the *citrus limetta*: it is limpid, yellowish, and fluid; that procured by pressure is not so fluid as that yielded by distillation, but its odour is more agreeable.

Essence of bergamot appears to consist of a mixture of two principles, one of which has the formula $C_{20}H_{16}$, whilst the second contains oxygen, and yielded to Soubeiran and Capitaine the following analytical results:—

Carbon	72.1
Hydrogen	10.8
Oxygen	17.1
	100.0

Placed in contact with anhydrous phosphoric acid, essence of bergamot forms *phosphobergamic acid*. The crude essence often deposits a camphor-like body called *bergaptene*, soluble in boiling water, in alcohol, and ether; its analysis leads to the empirical formula C_8H_8O .

The specific gravity of essence of bergamot is 0.888, its smell resembles that of oranges, and it is used as perfume; at a little below 32° Fahr. it becomes solid.

Vauquelin made a set of experiments to discover the effects that

were produced by the mixture of alcohol and this oil, in order that the fraud which is commonly practised of mixing them might be detected. He found that 100 measures of alcohol dissolved 50 measures of oil, but that there were several anomalies in the proportions in which smaller quantities of alcohol dissolved the oil. The general results are: 1. That the oil of bergamot may contain 8 per cent. of alcohol, of the specific gravity 0.817, without its being perceptible when mixed with water. 2. That when it contains a greater quantity of it, the surplus separates, dissolving about one-third of its volume of oil. 3. That a small quantity of water mixed with the alcohol diminishes remarkably its action upon the oil; since alcohol of specific gravity 0.880 dissolves only 1-28th of its volume, while pure alcohol dissolves almost half its volume. 4. That when we mix alcohol with a volatile oil, a mutual exchange takes place between the two fluids, the relation of which must vary with the purity of the alcohol; this last dissolves the oil, whilst the oil absorbs the alcohol. 5. That when we mix alcohol of specific gravity 0.847, for example, with oil of bergamot, which is, 0.856, the alcohol sinks to the bottom, and the oil swims upon it: this depends upon the oil absorbing a part of the pure alcohol, and thus rendering the remainder more dense, while it becomes itself more light. 6. That there takes place a kind of decomposition of the water and alcohol by the oil; from which it may be suspected that, if we were to mix a small quantity of diluted alcohol with a large quantity of volatile oil, the water would be separated, and be precipitated alone to the lower part of the vessel. Hence we learn that the dealers in perfumes may introduce 8 per cent. of alcohol into them without our being able to detect the fraud by the ordinary means; but it may be discovered by the assistance of the spirit hydrometer, as the density will be diminished by about 1-100th part. Sulphuric ether does not act on the oil of bergamot like alcohol; it unites with it in all proportions, and the fluids do not afterwards separate.

BERGAPTENE. [BERGAMOT, ESSENCE OF.]

BERLIN WORK. [EMBROIDERY.]

BERME, in fortification, is a kind of terrace formed at the foot of a parapet on the exterior side. It is generally in a horizontal position, about the level of the natural ground, and it separates the escarp, or that side of the ditch which forms the face of the rampart, from the outward slope of the parapet.

The berme prevents the earth constituting the parapet, when that work is damaged by rain or otherwise, from falling into the ditch. Its breadth is usually from two to three feet, and the ditch being at that distance from the foot of the parapet, the pressure of the latter against the escarp wall is in some measure diminished, a circumstance of considerable importance when the soil has not much tenacity. If the berme on the exterior of a bastion or ravelin is from 10 to 15 feet broad, it takes the name of *chemin des rondes*, and serves as a convenient post for sentries and as a path for the officers going their rounds to see that the troops are on the alert. It may also be useful as a station for the defenders, when opposing any attempt at an open assault by preventing the enemy from planting his scaling-ladders against the face of the escarp. Communications to the berme from the interior of the work are by passages through the parapet. It should be protected on the exterior by a hedge or a low wall, and the latter might be pierced with *loop-holes* for the defence of the ditches and covered-way.

Vauban, in his treatise on the defence of places, ascribes great importance to the *chemin des rondes*. He observes, that the ruins of the parapet, produced by firing at it from a distance, being retained on this part of the work, increase the height of the escarp, and thus compel the enemy, if he would form a practicable breach, to establish his batteries on the crest of the glacis, in order that he may be enabled to fire at and breach the wall near its foot. A broad berme is however liable to some objections, for its protecting wall is easily destroyed by the enemy's batteries, and it entails the rampart being wider than is in some cases convenient. Moreover, if the enemy should succeed in gaining it by an escalade, he might form there in good order, and mount the parapet in force. It must inevitably happen, also, that the missiles which the defenders might attempt to roll over the parapet upon the assailants while in the ditch would be intercepted by the berme. Vauban himself states that, at the siege of Gravelines, the besiegers were enabled to blow up the rampart by a mine; the *chemin des rondes* and part of its wall, which had been accidentally left standing, preventing the loaded shells, masses of stone, &c., which were thrown by the defenders over the parapet from falling near the miner who was employed in piercing the escarp. It is evident however that this rampart must have been entirely unflanked by the collateral works of the place.

The position of the *chemin des rondes* is indicated by the unshaded space on the exterior of the parapet along the faces and flanks of the work V, which is given in the article BASTION.

BERNARDINES, a branch of the Benedictine Order of Religious, more frequently called Cistercians. Their name of Bernardines was derived from St. Bernard, abbot of Clairvaux, or Clareval, in the diocese of Langres, about A.D. 1115, who was a great promoter of their order. [BERNARD, ST., in BIOG. DIV.] They were called Cistercians from Cistertium or Cîteaux, in the bishopric of Châlons in Burgundy, where the order was begun in the year 1098 by Robert abbot of

Molesme in that province, but brought into repute by Stephen Harding, an Englishman, third abbot of Cîteaux, who is therefore reckoned the principal founder. Their monastery and church here have been destroyed, and even of the ruins there are hardly any remains. They were also called White Monks from the colour of their habit. Fuller, in his 'Worthies,' book iii., probably errs, when he makes the Bernardines to be a stricter order of Cistercians.

The monasteries of the Bernardine or Cistercian Order, which became very numerous in a short time, were generally founded in solitary and uncultivated places, and were all dedicated to the Virgin Mary. It was a rule with the Cistercians not to allow another house, even of their own order, to be built within a certain distance. Stevens, in his continuation of Dugdale's 'Monasticon,' vol. ii., says, if we may believe the historians of this order, they had in all 6000 houses. The 'Histoire des Ordres Monastiques,' says, that within fifty years of its institution there were 500 abbeys of this order, and within a century they are stated to have had 1800. Their wealth was so great, that St. Bernard, the reformer of the order, states, that "he knew several abbots, each of whom had more than sixty horses in his stable, and such a prodigious variety of wines in his cellar that it was scarcely possible to taste the half of them at a single entertainment." (Mosheim's 'Ecclesiastical History,' MacLaine's edit., cent. xii. part ii., note.)

One of their most famous establishments in England was the abbey of Buckfastleigh, in Devonshire, some of the remains of which still exist, which was re-established as a Benedictine immediately after the Conquest. Here the monks, however, performed good service by introducing great agricultural improvements, and to the exertions of the monks of another of their abbeys at Birkland, founded in the 13th century, who attended particularly to their orchards, and grafted their trees with the choicest specimens from Normandy, the Devonshire cider may owe its repute if not its origin. (Dr. Oliver's 'Monasticon Diocesis Exoniensis,' 1846.) Manning and Bray, however ('History of Surrey'), state that the monastery of Waverley in that county, was the first house of the Cistercian Order established in England, although precedence was for a while claimed by the abbey of Furness in Lancashire. The 'Annals of Waverley,' printed by Gale, give a minute account of the dispute. The abbot of Waverley had precedence as well in the chapters of the Cistercian abbots through England, as a superiority over the whole order in this country.

In the 26 Hen. VIII. the number of Bernardine or Cistercian abbeys in England, of which thirty-six were among the greater monasteries, amounted to seventy-five, besides twenty-six Cistercian nunneries. Of the latter, one only was endowed with more than 200*l.* per annum. The total revenue of the Cistercian houses in England amounted to 18,691*l.* 12*s.* 6*d.*

Stevens, in his work already quoted, vol. ii. p. 23, has translated a long history 'Of the Original and Progress of the Order of Cistercians,' from the French 'Histoire des Ordres Monastiques,' &c., tom. v. Dugdale and Stevens, between them, have printed the rules and regulations of this order, with the various bulls of confirmation and privilege granted to it by different popes. Stevens has likewise given a list of the learned men of the Order of the Bernardines or Cistercians in England, thirty-six in number. St. Bernard's College in Oxford (since refounded as St. John's College) was founded by Archbishop Chichele, in 1437, for scholars of the Cistercian Order who might wish to study in Oxford, but had no place belonging to their order in which they could associate together, and be relieved from the inconveniences of separation in halls and inns, where they could not keep up their peculiar customs and statutes. The figure of St. Bernard still stands in a niche in the upper part of St. John's College tower.

St. Alberic, who became abbot of Cîteaux in 1099, drew up the first statutes of this order. The Harleian Manuscript 3708 (British Museum), a volume of the 14th century, contains another body of statutes for the order, compiled in the years 1289 and 1300.

The habit of this order was a white cassock with a black hood and scapulary, and a girdle of black wool round the waist; in the choir they wore a white cowl, and over it a hood with a rochet; when they went abroad they wore a cowl and great hood all black. The dress of the lay-brethren was of a dark colour, and their hood like that of the monks except in its hue. The Cistercian nuns wore a white tunic, black scapular, black girdle, and in the choir either cowls or mantles. The dress of the lay-sisters was of a dark colour; that of the noviciates white; and all wore a black veil and white wimple. (Fosbrooke's 'British Monachism,' 3rd edit., 1844.)

The abbot of Cîteaux in Burgundy continued to be the superior general and father of the whole Bernardine or Cistercian Order till the French Revolution.

The Reformation lessened their numbers in Germany. Attempts at removing the corruptions which wealth introduced, split the order into several branches; the various political changes in Germany have also diminished the number of their establishments, but several yet exist in Italy, Poland, Germany, and France. In the latter country, the most noticeable is that of La Trappe, of which a branch has been settled in England.

BERYL (*Rhombohedral Emerald; Aquamarine; Smaragd*), a precious stone found in primary rocks in Grenada, Salzburg, Siberia, Upper Egypt, Hindostan, and North America. It is of various shades of green and blue, and is distinguished as containing a considerable

amount of the rare earth *glucina*. A specimen of Siberian beryl, analysed by Klaproth, contained the following substances:—

Silica	66.45
Alumina	16.75
Glucina	15.50
Oxide of Iron	.60
	99.30

BETA-ORSELLI ACID. [LICHENS, COLOURING MATTERS OF.]

BETA-ORCEIN. [LICHENS, COLOURING MATTERS OF.]

BETH. [BEIT.]

BETROTHMENT. We sometimes hear of parties being *betrothed* to each other, which means that each has pledged his or her *troth* or *truth* to the other, to enter at some convenient time, fixed or undetermined, into the state of matrimony. It now has seldom any other meaning than that the parties have engaged themselves privately, sometimes, though it is presumed very rarely, in the presence of one or more friends who might, if necessity of doing so arose, bear testimony to such an engagement having been entered into. Even the rustic ceremonies which heretofore were in use to give some kind of formality to such contracts seem almost to have fallen into entire disuse. In ancient times however there were engagements of this kind of a very formal nature, and they were not thought unworthy the notice of the great legislators of antiquity. In the laws of Moses there are certain provisions respecting the state of the virgin who is betrothed. In the Roman law, the "*sponsalia*," or betrothment, is defined to be a "promise of a future marriage." It could take place after the parties were seven years of age. There was no fixed time after betrothment at which marriage necessarily followed, but it might for various reasons be deferred for several years. The *sponsalia* might be made without the two parties being present at the ceremony. ('Dig.' xxiii. t. i.)

The canonists speak of *betrothing* and of *marrying*, describing the former as being *sponsalia*, or *espousals*, with the *verba de futuro*, the latter with the *verba de presenti*. In England, there is no doubt that formal engagements of this kind were usual down to the time of the Reformation. One class of documents which have descended in families who have been careful in the preservation of their ancient evidences, are marriage contracts, which are generally between parents, and set out with stating that a marriage shall be solemnised between certain parties when they attain to a certain age, or at some distant period, as after six months or a year; and amongst the terms of the contract it is not unusual to find stipulations respecting the apparel of the future bride, and the cost of the entertainment which is to be provided on the occasion. When these contracts were entered into by the parents, there is reason to believe that the younger parties solemnly pledged their troth to each other.

The late Mr. Francis Douce, who was very learned in all matters relating to the popular customs of our own and other nations, describes the ceremony of betrothment ('Illustrations of Shakspeare and of Antient Manners,' vol. i. p. 108) as having consisted in "the interchange of rings—the kiss—the joining of hands, to which is to be added the testimony of witnesses." In France, where the ceremony is known by the name of *fiançailles*, the presence of the curé, or of a priest commissioned by him, was essential to the completeness of the contract. In England, such contracts were brought under the cognizance of the ecclesiastical law. Complaints are made by a writer about the time of the Reformation, cited in Ellis's edition of Brand's 'Popular Antiquities,' that certain superstitious ceremonies had become connected with these engagements; but Mr. Douce was unable to find in any of the ancient rituals of the Church any prescribed form in which this kind of *espousals* were to be celebrated. The Church however undertook to punish the violation of the contract. Whoever, after betrothment, refused to proceed to matrimony, *in facie ecclesiæ*, was liable to excommunication till relieved by public penance. This was taken away by stat. 26 Geo. II. c. 33, and the aggrieved party was left to seek his remedy by an action at common law for breach of promise of marriage. (Blackst. 'Comm.' Dr. Kerr's ed., v. i. p. 452.)

The northern nations, including the English and the Scotch, called this ceremony by the expressive term, *hand-fasting*, or *hand-fastning*. In Germany, the parties are called respectively "bride" and "bridegroom," "*bräut*" and "*bräutigam*," from the time of the betrothment (*verlobung*) until the marriage, when these designations cease.

BETULIN ($C_{40}H_{38}O_3$), a resinoid body obtained from the bark of the birch. It is colourless, insoluble in water, slightly soluble in alcohol, and very soluble in ether. It fuses at 392° Fahr., and may be sublimed in a stream of air.

BEVEL, or BEVIL, is the name applied both to the oblique angle formed by two surfaces which meet at either more or less than a right angle, and to the instrument employed by carpenters and joiners for taking and transferring such angles. The common carpenter's bevel consists of a straight wooden stock, mortised at one end to receive a thin blade, which is usually formed of steel, and attached to the stock by a pin in such a way that it may be turned to any required angle, and secured by a tightening screw. This kind of bevel may be described as an adjustable T-rule, the transom of which may be placed at any required angle with the stock. In some cases the pin or pivot which connects the blade with the stock passes through a slot or long

opening in the blade or transom, so that its arms may be made of unequal length. Hebert describes, in the 'Engineer's and Mechanic's Encyclopædia,' an instrument of the bevel kind for gauging, and transferring to work or paper an oblique angle of which one side is curved. It consists of two rulers, *a* and *b*, pivoted together at *c*, and capable of being set to any angle by means of the brass arc *d*, which is attached firmly to the ruler *b*, and passes through a mortise or slit in *a*, in which it may be secured at any point by means of a binding screw. The adaptation of the instrument to a curved surface is provided for by a flexible blade or riband of steel, *e*, secured to the ruler *a* at one end, but capable of being made to assume and retain any simple curve by means of the series of screws marked *ff*, which pass through nuts or mortises attached to the ruler *a*, and press against the steel riband by a kind of swivel-joint, which provides for the various angles of contact formed by the riband and the screws.

Where many articles have to be worked to the same angle, it is desirable to use a fixed bevel, made to the required angle, especially where one or both of the limbs are curved. When the interior angle of the bevel is that used by the workman, such an instrument is sometimes called a *joint-hook*: a familiar instance of its use in this way is in working the intradoses and radiating beds of arch-stones, which, for circular arches, will be alike in every part of the arch.

BEY. [BEG.]

BEZA'S CODEX, a celebrated manuscript, containing the Four Gospels and Acts of the Apostles, written in Greek, with a corresponding Latin text on every opposite page. Of the Greek text we shall speak more particularly presently. The Latin version is believed to be the 'Vetus Italica,' the old Italic, before it was corrected by St. Jerom.

This singular manuscript was presented to the university of Cambridge by Theodore Beza in the year 1581, whence it has its name of 'Codex Bezae,' and is sometimes cited as 'Codex Cantabrigiensis.' It is a thick quarto volume, written upon vellum, in uncial letters of the square form, that is, in large capitals quadrated, as distinguished from the sharper uncials. The letters, in some places, particularly in the beginning of the first leaf, are scarcely legible. The gospels are placed in the usual order of the Latin manuscripts,—Matthew, John, Luke, Mark. This codex has no stops, marks of aspiration, or accents.

There are various chasms in this manuscript, which, both in the Greek and Latin texts, have been supplied at later periods. The defective passages in the Greek are Matthew i. v. 1 to 20; vi. v. 20, to ix. v. 2; xxvii. v. 2 to 12; John i. v. 16 to iii. v. 26; Acts viii. v. 29 to x. 14; xxi. v. 2 to 10, and 15 to 19; xxii. v. 10 to 20; lastly, xxii. 29 to the end of the MS. In the Latin version the chasms are Matthew i. v. 1 to 12; from v. 8 in chap. vi. to viii. 27; from xxvi. 65 to xxvii. 2; from John i. 1 to iii. 16; Acts viii. 19 to x. 4; xx. 31 to xxi. 3, and 7 to 11; xxii. 2 to 10; and lastly, from Acts xxii. 20 to the end.

In the year 1787, immediately after the appearance of the New Testament of the Alexandrian Manuscript, published by Dr. C. G. Woidè, the university of Cambridge appointed Dr. Thomas Kipling, late fellow of St. John's College, and Deputy Regius Professor of Divinity, to edit this their highly-prized manuscript in fac-simile: that is, as far as metal types could be made to represent it, for a real absolute fac-simile can be obtained only by engraving. It appeared in 1793, in two volumes folio, edited with fidelity, accompanied by a preface of twenty-eight pages, and followed by twenty-four pages of notes, entitled, 'Codex Theodori Bezae Cantabrigiensis, Evangelia et Apostolorum Acta complectens, quadratis literis Græco-Latinus: Academia auspicante, venerandæ has vetustatis reliquias, summâ quâ potuit fide, adumbravit, expressit, edidit, Codicis historiam præfixit, notasque adjecit Thomas Kipling, S.T.P. Coll. Div. Joan. nuper socius.'

Dr. Kipling, in his preface, endeavours 1st, to establish the high antiquity of his MS.; 2ndly, he points out its peculiar character and excellence; 3rdly, he traces its migrations; and lastly, he describes its form.

It is allowed by all palæographers that Beza's MS. is one of the most ancient of its kind. The Rev. Henry Alford, in his edition of the Greek Testament (1856), says, "the general opinion now is, that it was written in the latter end of the 5th or 6th century." Wetstein and J. D. Michaelis deemed it much older; and Dr. Kipling was of opinion that it was more ancient than the Alexandrian MS., and must have been written in the 2nd century. His conjecture is founded on these circumstances, that it wants the doxology at the end of the Lord's Prayer, and has the Ammonian sections without the Eusebian canons. That the doxology is an interpolation there can be little doubt; but that the want of it in a MS. is a proof of the high antiquity of that MS. cannot so readily be admitted. If the writer of Beza's MS. were a Latinist, he might leave out the doxology in his Greek copy, because it was not in his Latin copy; or his Greek copy might have been one of those which wanted the doxology. The argument derived from the entire omission of the Eusebian canons, and from the Ammonian sections being added by a posterior writer, is more specious. Dr. Kipling hence infers that the text of the MS. was written antecedently to the date of the Ammonian sections, and these before the Eusebian canons appeared. Ammonius lived in the 3rd, Eusebius in the 4th century: the Ammonian sections in Beza's MS. are much posterior to the text, and are without the canons of Eusebius; therefore he considers it highly probable that those sections were added to the MS. before the fourth, and that the manuscript itself was written before the third century.

As to the nature and excellence of the Beza manuscript, great diversity of opinion subsists. Antony Arnauld ('Dissertation Critique touchant les Exemplaires, sur lesquels M. Simon pretend que,' &c., 8vo. Col. 1691) insisted that it was a forgery of the 6th century, and therefore unworthy of credit; and his chief argument was, that it has certain additions or interpolations which are not found in the copies anterior to that period; such as that in Matthew xx. 28, *ὁ υἱὸς τοῦ ἀνθρώπου*, &c.; that in Luke vi. 5, *τῇ αὐτῇ ἡμέρᾳ*, &c. This reasoning would be solid, if the assumption were just; namely, that these and similar interpolations were not found in any other MS. before the 6th century. Dr. Kipling draws from the same circumstance a very different conclusion: he thinks that the aforesaid additions are proofs that either the Beza MS. or its archetype must have been written before Jerom corrected the text of the New Testament, because they are not in his version. Bengel supposes this MS. to be of British origin from its great conformity with the Anglo-Saxon version, and to have been reformed, or rather corrupted, according to the Italic version. To this argument it is answered, that the Beza MS. resembles the Syriac version as much as it does the Italic and Anglo-Saxon. Michaelis, in his account "of the manuscripts that have been used in editions of the Greek Testament" ('Introduct. to the New Test.' 8vo. Cambr. 1793, vol. ii. p. i. pp. 228, 229) is of this opinion, in which he is corroborated by Professor Storr, who, in the eighth section of his 'Observationes super Novi Testamenti Versionibus Syriacis,' produces various examples in which the Syriac version coincides with the 'Codex Cantabrigiensis,' and at last conjectures that the latter has, in some cases, been improperly altered from the former, through a mistake of the Syriac text. Dr. Alford says, "the text is a very peculiar one, deviating more from the received readings and from the principal MS. authorities than any other. It appears to have been written in France, and by a Latin transcriber ignorant of Greek, from many curious mistakes which occur in the text and version attached. It is closely and singularly allied to the ancient Latin versions, so much so, that some critics have supposed it to have been altered from the Latin, but apparently without reason. Its peculiarities are so great, that in many passages, while the sense remains for the most part unaltered, hardly three words together are the same as in the commonly received text. And that these variations often arise from capricious alterations is evident from the way in which the Gospels, in parallel passages, have been more than commonly interpolated from one another in this MS. The concurrence with the ancient Latin versions seems to point to a very early state of the text, and it is impossible to set aside the value of it as an index to its history; but in critical weight it ranks the lowest of the four leading MSS." (that is, the Codex Alexandrinus, now in the British Museum; the Codex Vaticanus, in the Vatican Library; the Codex Regius Parisiensis, in the Imperial Library at Paris; and that of Beza, of which we have just treated.)

In noticing what Dr. Kipling calls the "migrationes," or peregrinations of the Codex Bezae, he gives it as his opinion, from internal evidence, that it was written in Egypt: others have been persuaded that it was written in the West, not by a Greek, but by a Latinist. By what means this manuscript passed to France is unknown. Beza, who presented it to the university of Cambridge, had himself received it about nineteen years before. He states it to have been found, in 1562, in the monastery of St. Irenæus at Lyon. Beza was at that time resident at Geneva. It has been supposed by some critics to be the manuscript which was produced in the Council of Trent, in 1546, by the bishop of Clermont, and which Drathmurus mentions 400 years before that council; but this is mere conjecture, and scarcely amounts to a probability.

BEZANT, a gold coin struck at Constantinople by the emperors of that city, anciently called Byzantium. William of Malmesbury says expressly, 'Constantinopolis primum Byzantium dicta. Formam

antiqui vocabuli præferunt imperatorii nummi Bizantini vocati." ('Script. post Bedam,' edit. Saville, fol. 76 b.) This coin was called byzant, besans, bezantus, byzantius, byzantinus, byzanteus, and bixantius. The coins were in fact aurei, but as they were the only gold coin current in Europe for a considerable time, they went by the name of bezants among foreigners.

The Moors of Spain stamped also a gold coin called byzantius massamutinus. There was likewise the byzantius saracenatus, or saracenicus, struck by the sultans of Iconium in Lesser Asia; and byzantii melechini, so called from being coined at Malines in Flanders.

These bezants were not always of the same weight, fineness, or value, since we find them described as *aurei byzantii*; *aurei boni byzantii*; and *auri optimi byzantii*. Ducange quotes this last expression from a charter of the year 915. (Apud Ughellum, tom. i. pp. 853, 960.) The aurei, or bezants, of Constantine, were to be of the weight of seventy-two to the pound of gold.

Byzantii albi, seu argentei, white or silver bezants, also occur in the 'Constitutiones Odonis legati Apost. in Cypro,' au. 1248. Ducange quotes a charter of 1399, which speaks of white bezants of Cyprus. They likewise occur in a bull of Pope Gregory IX. (Apud Ughellum, tom. vii. p. 60.)

The Moorish bezants are sometimes called in old writers marabotini, or maurabotini. They are mentioned by this name in Matthew Paris, 1176. ('Hist. Major,' edit. 1684, p. 110.) See also Ralph de Diceto under the year 1177. ('Script.' x. Twysd. col. 598.) From Ducange we learn that "Morabotini boni Alfonsini, auri fini et ponderis recti," frequently occur in Aragonese charters towards the close of the 13th century. The Moors in Spain had also gold trientes, or the third of a bezant, but all these coins were of very limited circulation.

Camden, in his 'Remains concerning Britain,' noticing the coined and other money in use among our Saxon ancestors, says, "Gold they had also, which was not of their own coin, but outlandish, which they called in Latin bizantini, as coined at Constantinople sometimes called Bizantium, and not at Besançon in Burgundy. This coin is not now known, but Dunstan, archbishop of Canterbury (as it is in the authenticated deed), purchased Hendon in Middlesex of King Edgar to Westminster for two hundred bizantines. Of what value they were was utterly forgotten in the time of King Edward III.; for, whereas the bishop of Norwich was condemned to pay a bizantine of gold to the abbot of St. Edmundsbury for encroaching upon his liberty (as it was enacted by parliament in the time of the Conqueror), no man then living could tell how much that was, so as it was referred to the king to rate how much he should pay."

In Domesday Book no mention whatever occurs of the bezant; but it occurs twice as a denomination of money, in the Winton Domesday of the year 1148, and several times in the Boldon Book, a survey of the palatinate of Durham made in 1183; both printed among the 'Supplementary Records' to the Great Domesday. The monks of Oseney, in consideration of the manor of Hampton-Gay in Oxfordshire, in the 6th of King Stephen, gave ten marks of silver to Robert de Gait, and one bizantine to his wife. (Kennet's 'Parochial Antiquities of Oxfordshire,' edit. 1695, p. 97.) Madox in his 'History of the Exchequer,' says, that in Henry II.'s time, Cressalin the Jew of Winchester, was amerced one hundred marks, and he paid instead thereof, one hundred bezants, which were accepted by the king, *mera gratia*. ('Mag. Rot.' Henry II. rot. 10, art. 'Sudhantescira.') Madox also says ('History of the Exchequer,' p. 711), that in the 17th year of King John, 10s. of Venetian money, and two bezants, were used at the Exchequer for counters: the Venetian shillings valued at 15s. and the two bezants at 3s. 6d. These of course were silver bezants. From the narrative of William de Braose's treasons (recorded in the Black and Red Book of the Exchequer) against King John, it is clear that silver bezants were in use in that reign; for when Maud, Braose's wife, was to make the first payment of a fine of 40,000 marks, which she and her husband had consented to pay on being restored to the king's favour, she told the justiciary, and the rest who were sent to distrain upon their goods, that they must expect nothing, she having no more money in her purse than twenty-four marks of silver, twenty-four shillings of bezants, and fifteen ounces of gold. (See Dugdale 'Baron.' tom. i. pp. 416, 417.) John of Glaston, in his 'Chronicle' (vol. i. p. 224) informs us that Michael, abbot of Glastonbury, dying 1253, left to his successor "quadraginta bisancios et viginti libras sterlingorum." Chaucer names the "besaunt" in the 'Romaunt of the Rose,' and Wycliffe, in his translation of the New Testament (Luke, c. xv. v. 8, 9), uses the term "besauntis" for the ten pieces of money in the parable.

The probability seems to be that the bezant of gold was current in England, if not from the 9th, certainly from the 10th, century, till the time of Edward III., when the coinage of the English noble drove it out of use.

The Constantinopolitan bezant was the coin which we still see in our cabinets in gold, in the form of an umbo, or hollow dish, frequently bearing the portrait of our Saviour. The weight of one of those of Alexius Comnenus I., who reigned from 1081 to 1118, is seventy grains. The Moorish bezants were flat. The Constantinopolitan bezant seems to have been generally of about the value of a ducat, or nine shillings. The name was probably given in the middle ages to

the gold coins of most countries. Cotgrave says that Henry II. of France coined bezants.

The white, or silver bezant, in the 16th year of Stephen, according to an instrument quoted in Kennet's 'Parochial Antiquities,' edit. 1695, p. 10, was of the value of 2s. No silver bezant is at present known to exist, at least under that denomination, in the cabinets of our collectors: but Constantinopolitan coins of silver, of the same size and form with the gold bezants, are found in cabinets, of the 12th and later centuries: they usually weigh about forty or forty-three grains.

Banduri and other writers call both the gold and silver coins of Constantinople, which we have described, *Nummi Scyphati*.

Camden ('Remains,' p. 236), says, that in the court of England, the piece of gold valued at 15*l.*, which the king was anciently accustomed to offer on high festival days, was called a bizantine: "which anciently was a piece of gold coined by the emperors of Constantinople; but, afterward, there were two," probably meaning bars, "purposely made for the king and queen, with the resemblance of the Trinity, inscribed 'In honorem sanctæ Trinitatis,' and on the other side the picture of the Virgin Mary, with 'In honorem sanctæ Mariæ Virginis,' and this was used till the first year of King James, who, upon just reason, caused two to be new cast, the one for himself, having on the one side the picture of a king kneeling before an altar, with four crowns before him, implying his four kingdoms, and in the circumscription, 'Quid retribuam Domino pro omnibus quæ tribuit mihi?' On the other side a lamb lying by a lion, with 'Cor contritum et humiliatum non despiciet Deus.' And in another for the queen, a crown protected by a cherubim, over that an eye, and 'Deus' in a cloud, with 'Teget alâ summus;' on the reverse a queen kneeling before an altar, with this circumscription, 'Piis precibus fervente fide humili obsequio.'"

By the treaty for the deliverance of the French king St. Louis, and the other prisoners made at the battle of Mansoura and elsewhere, between the commissioners of his majesty and the sultan of Babylon, it was agreed that the king should pay to the sultan 1,000,000 (dix cens mils, Joinville says) gold bezants, which were then worth, according to the recital of the Sieur de Joinville, 500,000 livres. The sultan afterwards remitted a part, on the king's frank agreement to the sum proposed, and it was thereupon reduced to 800,000 gold bezants. (Joinville, 'Histoire de St. Louis,' ed. Michel, p. 104.)

Bezant is represented in heraldry by round pieces of gold without any impression, and are held to signify the coins by which the stipends of the higher soldiers of the army in the holy wars are supposed to have been paid. They are, with us, always emblazoned gold, but the foreign heralds make them both gold and silver. In English heraldry when the figures are blazoned argent they are called plates.

BEZOARIC ACID. [ELLAGIC ACID.]

BEZOARS. [ELLAGIC ACID.]

BEZOARS. The most probable etymology of the word bezoar is from the Persian *Pâd-zahr*, that is, "expelling poison, the expeller of poison." The stone bears this and other designations of similar import in Persian; for example, *Bâd-zahr*, which seems to be a corruption of *Pâd-zahr*. The word *pâd* means "relieving, curing, removing (disease)," and *zahr* is "poison." Bezoars are substances found in various parts, but chiefly in the intestines, of land animals, and which were regarded as antidotes to all poisons, as well as supposed to possess other extraordinary virtues. Hence any substance which possessed, or was thought to possess, important qualities, was termed *bezoardic*, to indicate its value. Bezoars are either natural or artificial; but even the natural ones, being the result of disease, are not invariably met with in the animals which produce them. Their rarity, as well as the preternatural virtues ascribed to them, contributed to make them prized; on which account they have sometimes been sold for ten times their weight of gold. Those which were most esteemed came from the East, and were the earliest used. The most highly-valued of these was obtained from the stomach of the *Capra Aegagrus*, or wild goat of Persia. This was called by way of eminence *Lapis Bezoar Orientalis*. The greater number of bezoars are procured from ruminating animals, and in many instances they are nothing more than some portion of their food agglutinated into a ball by the secretions of the intestinal canal. Similar formations are sometimes found in the human stomach or intestines, especially in persons who live much upon vegetable or farinaceous food. (See Monro, 'On the Morbid Anatomy of the Gullet,' &c.) The bezoars from the west, called also American, are chiefly obtained from the *Auchenia Lama* and *Auchenia Vicuña*, Illig. These have been analysed by Proust, and found chiefly to consist of phosphate of lime. (See 'Ann. de Chimie,' vol. i. p. 197.) The oriental and some other bezoars were analysed by Fourcroy and Vauquelin. (See 'Ann. du Muséum d'Hist. Nat.' i. 93, iv. 334.)

Bezoars, though still esteemed in the East, have long fallen into merited disuse in Europe. Various artificial bezoars were often fraudulently substituted for the genuine; but these are not to be confounded with certain metallic preparations, chiefly of tin, silver, mercury, and lead, the composition of which was well known, and only designated bezoars from their power in curing diseases; these, if employed in the present day, are designated by other names, and will be noticed under the heads of the metals and their preparations.

The *Bezoardicum animale* was the name given to the heart and liver

of vipers, which, with other disgusting articles, were once used in medicine, but are now laid aside.

BIBLE, *Βιβλία*, *Biblia*, meaning *books*, is the name which was given in the 5th century by Chrysostom to the collection of sixty-six writings which are recognised by Christians as divine. To these sixty-six sometimes are erroneously joined about fourteen apocryphal writings, so that the total number amounts to about eighty, of which thirty-nine are in the Old, and twenty-seven in the New Testament.

Before Chrysostom, the more complete expressions for Bible were *βιβλία θεία*, *books divine*; or *ἱερὰ γραφή*, *θεία γραφή*, *ἁγία γραφή*, *sacred writings*, &c.

"Independently of all consideration of its religious advantages, no book has conduced more than the Bible to the high cultivation and moral advancement of the human mind. The labour bestowed by so many of the learned upon the just interpretation of this inestimable book is of itself an attestation of its worth, and countenances the supposition that Divine Providence has appointed it for the attainment of great designs. So long as the professors of that religion, whose doctrine and morals are contained in the Bible, apply themselves, as they have hitherto done, to explain its contents, the learning of Christians will be eminently conspicuous. Nay, a well-grounded system of biblical interpretation presupposes no slight degree of knowledge, and compels the instructors of the rising clergy to apply themselves closely to literary pursuits, in order to acquire a knowledge of the ancient oriental languages; of the most celebrated works of the Greeks and Romans; of ancient history; and of many sciences for which the constant exercise of the power of thinking is required. It cannot be denied that the interpreters of Holy Scripture, both Jews and Christians, have often swerved from the truth, and introduced error, superstition, and prejudice, instead of a sound knowledge of religion and ethics. But it was precisely the want of a well-regulated and systematic scheme of interpretation, which produced such disorders of a fanatical imagination, or, to say the least, such palpable aberrations of the understanding. As, even with the possession of much knowledge, both philological and philosophical, numerous and long-continued errors have been mixed up with the important work of biblical interpretation, it is evident that a system of interpretation, founded on sound principles of reason—on philology, grammar, and history, is in the highest degree necessary for future teachers of religion." (Seiler's 'Biblical Hermeneutics'.)

The Bible is divided into the Old and the New Testament. At present we confine our observations to the Old, which is written in Hebrew, with the exception of some chapters in Daniel and Ezra, and a verse in Jeremiah written in Chaldee.

The name *Old Testament* was introduced by the apostle Paul, who wrote concerning the Jews: "Their minds were blinded: for until this day remaineth the same veil [put over the face of Moses] untaken away in the reading of the *Old Testament*," 2 Cor. iii. 14.

The Greek expression *παλαιά διαθήκη* (*Palaiā Diathēke*) means *old covenant* or *old testament*, and was translated in the Latin Vulgate, *Vetus Testamentum*. This name became usual among those European nations who recognised the supremacy of the Roman See and the authority of the Vulgate; but Slavonic nations, for instance the Russians and Poles, divide the Bible into the Old and the New Law. Tertullianus ('adv. Marcionem,' iv. 1.) and Augustinus ('de Civitate Dei,' xx. 4. epist. Pelag. iii.) call the Old Testament *Vetus Instrumentum*.

The following ancient appellations given to the Old Testament are more or less expressive of the veneration in which it was held: **הַפְּתוּחַ בְּתוֹכָהּ**, *הַפְּתוּחַ בְּתוֹכָהּ* (2 Pet. i. 20), *αἱ γραφαὶ* (Matt. xxii. 29; Acts xviii. 24.)

הַפְּתוּחַ בְּתוֹכָהּ, *γραφὰι ἁγίαι* (Rom. i. 2); *ἱερὰ γράμματα* (2 Tim. iii. 15.)

הַפְּתוּחַ בְּתוֹכָהּ, *סִפְרֵי הַקְּדָשׁ*, *τὰ βιβλία*, *הַתּוֹרָה*, *δ νόμος* (John xii. 34).

δ νόμος, *οἱ προφήται* καὶ *οἱ ψαλμοὶ* (Luc. xxiv. 44).

δ νόμος καὶ *οἱ προφήται* (Acts xxviii. 23, &c.), *δ νόμος*, *οἱ προφήται* καὶ *τὰ ἄλλα βιβλία*, Tes. Sir. Prol.

הַפְּתוּחַ בְּתוֹכָהּ, *הַפְּתוּחַ בְּתוֹכָהּ*: *סִפְרֵי הַקְּדָשׁ* (comp. Neh. viii. 8, where this word occurs, but in a different sense), **הַפְּתוּחַ בְּתוֹכָהּ**, *βιβλία τῆς παλαιάς διαθήκης*, *vetus Testamentum*, sive *Instrumentum* (compare *ἡ παλαιά διαθήκη*, 2 Cor. iii. 14, *βίβλος τῆς διαθήκης*, 1 Mac. i. 57; 2 Kings xxiii. 2, according to the Septuagint).

The names of the New Testament are, *τὸ εὐαγγέλιον* καὶ *ὁ ἀπόστολος*, or *τὸ εὐαγγελικὸν* καὶ *τὸ ἀποστολικὸν*, or *ἡ καινὴ διαθήκη*, *Novum Testamentum*, sive *Instrumentum*.

With the collection of the Old Testament arose its division into

1. **הַתּוֹרָה**, *νόμος*, *lex*, law, i. e., the five books of Moses.

2. **נְבִיאִים**, *προφήται*, *prophetæ*, prophets.

These **נְבִיאִים**, or prophets, are subdivided into **נְבִיאִים רִאשׁוֹנִים**, "the former prophets" (containing the books of Joshua, Judges, Samuel, and Kings), and into **נְבִיאִים אַחֲרֵיכֵן**, "the later prophets." The later prophets (which we alone call prophets, Isa. Jer. Ezech. &c.) are again divided into **גְּדוֹלִים**, "the great;" and **קְטָנִים**, "the small,"

עֶשְׂרֵי תְּנָכִים, *βίβλος τῶν δώδεκα προφητῶν*, τὸ *δωδεκαπρόφητον*, i. e., the twelve minor prophets.

3. **כְּתוּבִים**, *γραφεῖα ἁγιογγραφα*, holy writings, containing the Psalms, Proverbs, Job, Song of Songs, Ruth, Lamentations, Ecclesiastes, Esther, Daniel, Ezra, Nehemiah, two books of Chronicles.

The Jews being fond of making new names of the initials of other appellations, call the three first books of their **כְּתוּבִים**, "holy writings,"

by the name of "the books," **אִמֶּת** from **אִיּוֹב** Job, **מִשְׁלֵי** Proverbs, and **תְּהִלִּים** Psalms; the word **אִמֶּת** means *truth*. The books **אִמֶּת** are also called poetical books, and differ in their accentuation from the rest of the Hebrew Old Testament. Solomon's Song, or Song of Songs, Ecclesiastes, Ruth, Lamentations, and Esther, from the **מְגִלּוֹת**, i. e., *the five rolls*, so called because they are read on certain festivals in their synagogues from manuscript rolls, and are even printed in the shape of rolls. Christians reckon the Song of Songs and the Ecclesiastes among the poetical books, and they gave to Daniel the fourth place among the great prophets, who are called *great* because their remains are more voluminous than those of the so called *minor* prophets, although the latter are not inferior in matter and style.

From the initials of **הַתּוֹרָה**, **נְבִיאִים** and **כְּתוּבִים** the Jews make another name for the whole Bible **תְּנָכִים** *T'nach*, perhaps in allusion to the root **תָּנַח**, he *ceased*, or was *finished*.

If we count both books of Samuel, Kings, and Chronicles, we find that the Old Testament consists of thirty-nine books; but the Talmud counts only twenty-four books, because the twelve minor prophets are considered as one book, and the books of Samuel, Kings, Chronicles, Ezra, and Nehemiah constitute, according to the Talmudists, only four books. (Baba Bathra, f. 14, c. 2.) After the five books of Moses, the rest of the biblical books are enumerated as follows:—

סֵדֶר שֶׁל נְבִיאִים יְהוֹשֻׁעַ וְשׁוֹפְטִים שְׁמוּאֵל וּמְלָכִים יִרְמְיָהּ וְיִחְזְקָא יִשְׁעִיָּהּ וְתִדִּי עֶשְׂרֵי : סֵדֶר שֶׁל כְּתוּבִים

רוֹת תְּהִלִּים וְאִיּוֹב וּמִשְׁלֵי וְקִהְלֵת שִׁיר הַשִּׁירִים וְקִנּוֹת דָּנִיֵּאל וּמְגִלּוֹת אֶסְתֵּר עֶזְרָא וְדִבְרֵי הַיָּמִים

The arrangement of the Septuagint and Vulgate, which is followed in the English Bible, will be explained under **SEPTUAGINT**, and **VULGATE**.

Josephus, who was born A.D. 37, in a passage which we shall soon quote from Whiston's translation, enumerates twenty-two biblical books (*δύο μόνα πρὸς τοῖς εἴκοσι βιβλία*), which he probably numbered as follows:—

Five books of Moses.

1. Genesis.
2. Exodus.
3. Leviticus.
4. Numbers.
5. Deuteronomy.
6. Joshua.
7. Judges and Ruth.
8. Two Books of Samuel.
9. " " Kings.
10. " " Chronicles.
11. Ezra and Nehemiah.

The Prophets in thirteen books.

12. Esther.
13. Isaiah.
14. Jeremiah and Lamentations.
15. Ezekiel.
16. Daniel.
17. Twelve minor prophets.
18. Job.

The other four contain hymns to God and maxims for the conduct of life.

19. Psalms.
20. Proverbs.
21. Ecclesiastes.
22. Song of Songs.

This rather artificial arrangement arose from a desire of having as many and no more biblical books than there are letters in the Hebrew alphabet.

In the Ecclesiastical History of Eusebius (iv. 26), Meliton, in a letter to Onesimus, states that he travelled to the East in order to investigate exactly the nature of the Old Testament in those countries in which it was written, and where the events related therein happened; and that he found the following to be the names of the books contained in the Old Testament: *Μωϋσέως πέντε· Γένεσις, Ἐξοδος, Λευιτικόν, Ἀριθμοί, Δευτερονόμιον· Ἰησοῦς Ναυῆ, Κριταί, Ρουθ, Βασιλειῶν Τέσσαρες* (that is, 2 Sam. and 2 Kings), *Παραλειπομένων δύο, Φαλμών Δαβὶδ, Σολομώντος Παροιμίαι, ἡ καὶ Σοφία, Ἐκκλησιαστής, Ἄσμα ἁσμάτων, Ἰώβ· Προφητῶν, Ἡσαίου, Ἰερμίου τῶν δώδεκα ἐν μονοβίβλῳ, Δανιήλ, Ἰεζεκιήλ, Ἐσδρας*. Here we have Nehemiah and Esther omitted, but again the number twenty-two.

In the Ecclesiastical History of Eusebius (vi. 25), a passage from Origen is quoted, which states that, according to the tradition of the Hebrews, there are twenty-two canonical books, which is the number

of their letters. Origen seems to have forgotten the book of the twelve minor prophets; and so it happens that, having promised to count twenty-two books, he enumerates only twenty-one. In the Latin version of Eusebius by Ruffinus, the book of the minor prophets is inserted after the Canticles; and in a similar manner Hilarius expresses

himself in the prologue to the Psalms, which he translated from Origen.

After these observations the following diagram will be understood, and will facilitate the finding of Hebrew passages, since most Christians are accustomed to a different succession of biblical books:—

According to a Jewish tradition, Moses was the first who wrote. In the subsequent heroic times of the Hebrews we find the noting down of historical facts and the composition of poems; but Hebrew literature received its chief impulse at a later epoch from Samuel's "Schools of the Prophets," which produced the best specimens of moral or didactic and lyric poetry, and the finest prophetic compositions.

That several documents and books of ancient Hebrew literature have been lost, is in itself very credible, and it appears, from the difference of style, that Genesis is formed out of various documents. [GENESIS.] The book of Jasher is twice quoted (Jos. x. 13; 2 Sam. i. 18), but the compilations in Hebrew and in English extant under this title are forgeries. [JASHER.] The books of Chronicles and Kings are extracts from larger records, to which the reader is frequently referred by such phrases, "Now the acts of David the king, first and last, behold, they are written in the book of Samuel the seer, and in the book of Nathan the prophet, and in the book of Gad the seer," 1 Chron. xxix. 29. "And the rest of the acts of Solomon, and all that he did, and his wisdom, are they not written in the book of the acts of Solomon?" 1 Kings xi. 41. "Now the rest of the acts of Solomon, first and last, are they not written in the book of Nathan the prophet, and in the prophecy of Ahijah the Shilonite, and in the visions of Iddo the seer against Jeroboam the son of Nebat?" 2 Chron. ix. 29. Solomon "spoke three thousand proverbs, and his songs were a thousand and five," most of which are not extant now. Even by counting the subdivisions in the

Solomonic writings now extant, the above numbers cannot be produced. According to the rabbinical mode of counting stated in Hebrew at the conclusion of biblical books, the number of verses in the book of Proverbs is 915, in the Song of Songs 117, in Ecclesiastes 222.

With the restoration of the ancient constitution and manners there was excited a literary zeal for collecting those remains of national literature which were neglected during the Babylonian captivity. To this zeal for collecting the ancient holy writings the Old Testament owes its formation. But the zeal for national literature survived the national language, and accordingly the body of the Apocrypha was added, after the Old Testament had been brought to a conclusion, about B.C. 150. Ezra, and the other members of the great synagogue, have been frequently considered as the founders of the Canon; but the Talmudic passages upon which this opinion rests are by no means decisive; and we have therefore more reason to ascribe this merit to Nehemiah, concerning whom we read in the 2 Maccabees, ch. ii. ver. 13, "the same things also were reported in the writings and commentaries of Neemias, and how he founded a library, gathered together the acts of the kings and the prophets, and of David, and the epistles of the kings concerning the holy gifts. In like manner Judas also gathered together all those things that were lost by reason of the war we had; and they remain with us."

The most ancient record of the Old Testament as a collection is in the prologue of Jesus son of Sirach, about B.C. 130 under the appellation

of νόμος καὶ προφήται, "the law and the prophets." "Whereas many and great things have been delivered to us by the law and the prophets, and by others that have followed their steps, for which things Israel ought to be commended for learning and wisdom, and whereof the readers must not only become skilful themselves, but they also that desire to learn be able to profit them which are without both by speaking and writing; my grandfather, Jesus, when he had given himself much to the law and the prophets, and the other books of our fathers, and had gotten therein good judgment, was drawn out also himself to write something pertaining to learning and wisdom, to the intent that those who are desirous to learn and are addicted to these things, might profit much more by living according to the law." With this we may compare Luke, ch. xxiv. ver. 44; "All things must be fulfilled which were written in the law of Moses, and in the prophets, and in the Psalms concerning me." The Psalms seem here to be the representatives of the Hagiographa or holy writings, which constituted the third part of the Old Testament and followed the law and the prophets.

From the above passages we infer that the Old Testament existed as a collection in the two centuries preceding Christ.

Philo, who flourished about B.C. 41, seems likewise to appeal to the Old Testament as to a collection of books. (See Hornemann, 'Observationes ad Illustrat. Doctrina de Canone Vet. Test. ex Philone,' 1775.) But the clearest proof for the existence of our present canon of the Old Testament is to be found in the first book of Josephus 'against Apion,' c. 8; and compare 'Antiq. Jud.' lib. xi. cap. 6, s. 19.

When the Hebrew language died away, the canon of the Old Testament became closed.

The Samaritans recognised the authority of the Pentateuch only, and of the book of Joshua. They slightly interpolated the Pentateuch, but considerably altered the book of Joshua. Their rejection of the other books of the Old Testament may be compared with the opinion of Philo, according to which Moses alone is the teacher of religious mysteries, although he ascribes inspiration to the other books of the Old Testament as well as to his own writings.

During the first centuries after Christ, the writings of the New Testament were placed on a level with those of the Old. Both Testaments were publicly read; the Old Testament was read in the Septuagint translation or the Alexandrine version of the Hebrew into Jewish Greek. Hence it has arisen that Christian writers frequently cite as Scripture the Apocrypha which were mixed up in the Septuagint with the canonical books; but as soon as the attention of the learned was directed to the canon, the later products of Jewish literature subsequent to the extinction of the Hebrew language, were again separated from the canon. The canonical books were therefore called 'Libri Regulares,' or Regular Books, and the Apocryphal books 'Libri Secreti,' or Secret Books. But the reading of the 'Libri Secreti' continued during the 3rd century. In the 4th century several lists of Biblical books were promulgated by the orthodox Greek Church in order to prevent the use of Apocryphal or uncanonical books (ἀκανόνιστα βιβλία).

These lists generally adhere, in the Old Testament, to the Jewish canon; but fluctuate in the New Testament concerning the Apocalypse. The name 'Apocrypha' signifies in these lists fictitious and heretical writings; but between the canonical and Apocryphal is placed a third class of writings, the reading of which is permitted to the Church. The Latin Church adopted, with reference to the Old Testament, laxer principles, and admitted several Apocryphal writings into the canon; although the learned, like Hieronymus, adhered to the twenty-two books, according to the letters in the Hebrew alphabet. Hilarius also mentions that the law of the Old Testament was divided into twenty-two books, corresponding in number to the letters of the Hebrew alphabet; but adds that, according to the opinion of others, Tobit and Judith should be added in order to complete the number of the Greek alphabet; which contains twenty-four letters. The Protestants, returning to the Jewish canon, separated the Apocryphal additions of the Alexandrine version, which were for the first time decidedly made canonical by the council of Trent in opposition to the Reformers. The council of Trent decrees, in its fourth session, that if anybody will not admit as holy and canonical all the entire books and all their parts extant in the Latin Vulgate, he shall be *anathema*.

After these general remarks concerning the formation of the canon, we shall briefly survey the history of the text.

Before the Babylonian exile the Biblical books were written in the characters still extant in the legends of the Asmonæan coins, of which we have given specimens in the article ALPHABET. Instead of the antique Hebrew character which is nearly allied to the Samaritan, there was employed after the Babylonian captivity a sort of Aramaic alphabet, which was gradually changed by transcribers into the present square character, of which the Spanish, the German, and the intermediate or Italian are three modifications found in Hebrew manuscripts. The characters printed in modern editions of the Hebrew Old Testament are formed according to the Spanish manuscripts, which are the most beautiful. The characters employed in the publications of Sebastianus Münster at Basel about 1530, are imitations of German manuscripts.

The Italian and French Jews wrote in a middle style, between the Spanish and German. The Rashi, Rabbinical, and cursive Hebrew

characters represent the gradual changes of the square characters to a Hebrew running hand, which are also occasionally employed in manuscripts written for private use, and are therefore less accurately revised, and consequently of less authority than those written for public use in synagogues. The most ancient manuscripts had neither vowels nor diacritical marks, nor were the words always divided. (See Hupfeld, 'Beleuchtung dunkler Stellen in der alt-testamentlichen Textgeschichte. In den Studien und Kritiken,' 1830.)

Verses and punctuation, which are already mentioned in the Talmud, are marked in Hebrew by accents, which served also as rhythmical marks to be observed in the Oriental style of reading, which approaches to singing. Hieronymus followed probably the פסוקים, *sections*, mentioned in the Talmud, in dividing the prophetic and poetical books into *cola et commata*, and the historical books into *cola* only.

In old Hebrew manuscripts, as well as in those of the Septuagint and Italian version, the poetical books are written in hemistichs or half verses, thus:—

Sepulchrum patens est guttur eorum.
Linguis suis dolose agebant.
Venenum aspidum sub labiis eorum.

The present division into chapters, which the Jews have adopted, is of Christian origin, and does not occur before the 13th century. By some it is ascribed to Stephen Langton, Archbishop of Canterbury, who died in 1227; by others to Cardinal Hugo von St. Caro, who died in the same century. The Psalms was the first portion of the Old Testament numbered in verses, in the edition of Jaques le Febvre, printed by H. Stephens in 1539. The *capitula* of Hieronymus, the *Tituli* and *Breves* in the Latin, the סדרים or סדרין, *orders*, and סמנים (*σημεία*) *marks*, of the Masoreths, were so fluctuating that, before the introduction of the present chapters and verses, the quotations were very vague. The Pentateuch alone was in ancient times divided into fifty-four "sections," פרשיות, according to the number of the Sabbaths in the Jewish leap year.

On every Sabbath a certain *sederah*, or *parasha* or *section*, is read, and in the common year, which does not contain fifty-four Sabbaths, two sections are to be read on some Sabbaths, so as to complete the reading of the Pentateuch every year. The *Parashioth*, or "sections," are subdivided into seven smaller divisions, according to the number of men who are usually honoured by being called upon on the Sabbath to read publicly the law in the synagogue. But in these divisions and in accounting for them, neither the Jews nor the learned perfectly agree among themselves.

The *Parashioth*, which in regularly written manuscripts commenced a line, are called פתוחות, *open*, and are marked in printed Hebrew Bibles פפפ or פ. Those which commence in the middle of a line are called סתומות *closed* or *shut up*, and are marked ססס or ס. But in printed Bibles ס stands sometimes at the commencement, and פ in the middle of a line.

The *open* sections seem to point out the different topics treated of; the *close* mark, the most prominent and natural divisions of the open ones, such as the change of speakers, the incidents of a narrative, &c. The date of this division is not known, but is certainly older than the Mishna, in which it is quoted.

Notwithstanding the great care bestowed by the Jews after the Babylonian exile upon the preservation of the Hebrew text, some transpositions have crept in; letters, words, and sentences have been omitted; and some mistakes between ו. ב. ג. ד. &c., as well as errors in the division of the words and the filling up of abbreviations, &c., have been made; sometimes letters of a similar sound, synonymous words, and those of similar sound and parallel passages were exchanged. Some alterations were also introduced by the officiousness of critics in removing expressions which they either deemed offensive or hard to be understood, or not perfectly analogous to parallel passages. A comparison of the parallel passages in the Old Testament shows that these alterations happened most frequently in the most ancient times before the ecclesiastical authority of the canon was established. Comp. Ps. xiv. with liii.; xl. 14th seq. with lxx.; xviii. with 2 Sam. xxii.; Ps. cviii. with lvii. 8—12; lx. 7—14; Ps. cv. with 1 Chron. xvi. 8—22; Ps. cxvi. with 1 Chron. xvi. 23—33; Is. xxxvii. xxxviii. with 2 Kings xviii. xix.; Jer. lii. with 2 Kings xxiv. Compare also the parallel passages in the books of Samuel, Kings, and Chronicles; Is. xv. xvi. with Jer. xlviii. and other passages cited in Eichhorn's 'Einleitung,' i. pp. 139, 6; Bauer, 'Critica Sacra,' p. 236, seq.; Gesenius, 'Geschichte der hebräischen Sprache,' p. 38, seq. Although these alterations do not materially affect the tenor and scope of biblical doctrine, it has been the business of critics to collect and to compare the various readings of the Hebrew text, and thus to restore its original purity.

The oldest recension of the Hebrew text, coming from a quite different quarter, and being independent of the usually received text, is that of the Samaritan Pentateuch, which seems to be closely related to the copy from which the Septuagint interpreters translated. The various readings of the Samaritan Pentateuch were for a considerable time overvalued by some and despised by others, and herein both parties frequently showed more zeal than knowledge. But the

examination of the Samaritan text by Gesenius ('De Pentateuchi Samaritani origine, indole et autoritate Commentatio Philolol. crit. scripsit Guil. Gesenius; Hal. 1815, 4to) has shown that the assertions of the zealots against the Codex Samaritanus, although produced without reason, were not substantially wrong. Its character is uncritical; most of its characteristic readings have arisen from injudicious grammatical corrections, inserted glosses, explanatory conjectures, grammatical and historical additions and alterations according to parallel passages, Samaritanisms in language and doctrine, as for instance the substitution of Garizim, גרזים, for עיבל in Deut. xxvii. 4.

The Jews in Babylon and Palestine appear to have been more critical than those in Egypt and the Samaritans, because Aquila, and the other Greek translators after Christ, and Onkelos and Jonathan agree more with the Masoretical text than the Septuagint. About the time of the birth of Christ arose schools of learning, especially in law, grammar, and criticism. After the destruction of Jerusalem these schools were transplanted to Jabne, Ziphoria, Lydda, Cæsarea Palestina, formerly called Straton's Tower, on the coast of the Mediterranean, Tiberias, and at a later period to Sora, Pumpedita, and Nahardea on the banks of the Euphrates.

Origen, in composing the Hexapla, perused a Masoretical manuscript in the 3rd century after Christ, and in the 4th century Hieronymus employed Palestine teachers and MSS. The present received text originates from Palestine. Therefore the interpretations and readings of Hieronymus are nearly allied to the present received text. Many passages indicate that Hieronymus employed an unpointed text.

Eight MSS. form the basis of the text of the Old Testament. They are: the Codex Babylonicus, the Codex Palestinus or Egyptus, the Codex Sinai, an Egyptian MS. supposed to have been written at Jerusalem and carried to Egypt, the Pentateuch of Jericho, thought to be the most correct, the Codex Sanbaki, and the book Tagin containing the Pentateuch only. The Hebrew MSS. are superior on the whole to the Samaritan, yet the Samaritan was followed in the Septuagint and our Saviour has quoted from it, and the differences are but slight. It has been a question whence the Samaritans obtained their copy of the Pentateuch. Gesenius thinks that when the tribes were carried away captive to Assyria, some copies may have been left with the remnant, which passed into the hands of the mixed race afterwards called Samaritans.

The Talmud contains precepts of biblical calligraphy (Tr. Gittin, f. 45, c. 2), mentions a comparison of manuscripts (Hieros. Tr. Taanith, f. 68, c. 1, compare Tr. Sopherim, vi. 4), and refers to certain classes of biblical emendations prior to the Talmud, called by Morinus 'fragmenta' or 'vestigia recensionum;' by Eichhorn, 'Revisiones.' These classes are

I. **עֲמוּר סוּפְרִים**, ablatio scribarum, concerning the omission of **וָא** in Gen. xviii. 5, xxiv. 55; Num. xii. 14; Ps. lxxviii. 26, xxxvi. 7. See Nedarim, f. 37, c. 2.

II. **תְּקוּנֵי סוּפְרִים**, correctio scribarum, concerning sixteen or eighteen erroneous passages, for example, Gen. xviii. 22; 1 Sam. iii. 13.

III. **פּוּנְקְטָא עֲזָרָא** in fifteen words, for example, Ps. xxvii. 13, **לֹא לֵא**. Tr. Sopherim, vi. 3.

IV. **קָרִי וְלֹא קָרִי**, if there was anything to be read which was not written, 2 Sam. viii. 3, xvi. 23. Nedarim, f. 37, c. 2.

V. **קָרִי וְלֹא קָרִי**, if there was in reading to be omitted what was written in the text, as in 2 Kings v. 18.

VI. **קָרִי וְכֵתִיב**, various readings, as Job xiii. 5, Hagg. i. 18.

After the conclusion of the Talmud in the 6th century, the Jewish scribes continued, especially in Tiberias, to propagate their critical traditions, at first orally, afterwards by writings; these writings were afterwards placed in the margin of the manuscripts. Subsequently those critical remarks were improved and augmented by the so called

בְּעֵלֵי מִסּוּרָה "the lords of the Masora," who also counted the number of the verses, of the words, and of the consonants in the biblical books.

There exists also in the rabbinical bibles of Bomberg and Buxtorf, and in the sixth volume of the London Polyglott, a list of various readings by Rabbi Aharon Ben Asher, and Rabbi Jacob Ben Naphthali, of the 11th century. The readings of Ben Asher are preferred by the western, and those of Ben Naphthali by the eastern Jews. From the circumstance that their observations regard exclusively the vowels and accents, we conclude that the punctuation of the text was already accomplished in their days, and that they employed punctuated manuscripts.

After the origin of the Masora, the MSS. were probably often altered accordingly. But we have reason to think that no material change took place, because even the complaint of Meir Hallevi about the corruption of the manuscripts refers especially to abbreviations which do not affect the sense. The famous MSS. of the rabbins in the middle ages, as that of Hillel, Ben Asher (called the Egyptian or Hierosolymitan), and that of Ben Naphthali and others, adhered to the

Masora. The following are among the more important editions of the various texts:—

The earliest editions of the Hebrew bible were imitations of ancient manuscripts, and have therefore critical authority. The oldest Hebrew prints contain only parts of the Old Testament. The oldest specimen of Hebrew typography contains the Psalms with the Commentary of Kimchi, 1477, probably printed at Bologna. A very old specimen of Hebrew typography was presented by Dr. Pellet, in 1735, to the library of Eton College, containing the Cethubim or Hagiographa, printed at Naples in 1487. This edition was burnt by the Jews, probably on account of its readings frequently differing from the Masora, which was considered already at that period the standard of correctness. The copy at Eton is printed on vellum, and is considered the only one that escaped the flames.

I. The first complete edition of the Hebrew bible was printed at Soncino, in the Cremonese territory in the dukedom of Milan, 1488, small fol. The edition of Brescia, 1494, 4to, which Luther translated, generally follows the text of this Editio Princeps. (See J. G. Palm de Codicibus Veteris et N. T. quibus b. Lutherus in conficienda interpret. Germ. usus est, Hamb., 1753. B. W. D. Schulz vollst. Kritik ü. d. gewöhnlichen Ausgaben d. Hebr. Bibel nebst einer Nachricht v. d. Hebr. Bibel welche Luther bei s. Uebersetzung gebraucht, Berlin, 1766, 8vo.) To this first edition of printed bibles belong also, Bibl. Rabbinica, Bombergii ed. Felix Pratensis, 1517, and the smaller editions printed by Bomberg in 1518, and in 1521, 4to: the edition of Robert Stephanus, 1539-1544, 4to: and Bibl. Hebraica stud. Seb. Münsteri, Basileæ, 1534-1536, 4to, two volumes.

II. An independent text, which became the basis of other editions, is contained in the Biblia Polyglotta Complutensia, finished in 1517, but not published till 1522. Alvarez Gomez de Gestis Francisci Ximenii (Compluti. 1569, fol. L. ii. p. 47) says that there were bought for 4000 aurei, seven Hebrew MS. copies from various countries, and that these copies were preserved at Complutum (Alcala). From this second edition proceeded Bibl. Polygl. Bertrami ex offic. Sanctandr. 1586, fol. (also ex offic. Commelin, 1599, 1616).

III. Bibl. Rabb. Bomberg. II. Cur. R. Jac. B. Chajim, Venet. 1525-26, fol. Although Jacob Ben Chajim in this edition followed the Masora more than the MSS., it influenced strongly most of the subsequent editions, and the following belong entirely to this third recension: Biblia Rabb. Bomberg. III., Venet. 1547-1549, fol.; Bibl. Rabb. per Jo. de Gara, Venet. 1568, fol.; Biblia Rabb. Bragadini, Venet., 1617-18, fol.; Bomberg's quarto editions of 1528, 1533, and 1544; the edition by R. Steph., Paris, 1544-46, in 16mo; some alterations were made in the Justinian editions, Venet., 1551, 4to; 1552, 18mo; 1563, 4to; 1573, 4to; B. Hebr. Genev., 1618, in 4to, 8vo and 18mo; B. Hebr., per J. de Gara, Venet., 1566, 4to; 1568, 8vo; 1682, 4to; B. Hebr. typ. Bragadin., Venet. 1614-15, in 4to and 12mo, 1619, 4to, 1628, 4to, 1707; Bibl. Hebr. Chr. Plantin. Antv. 1566, in 4to, 8vo, and 16mo; Biblia Hebraica, Hartmanni Fref. ad Viadr. 1595, in 4to, 8vo, and 16mo; 1598, 4to; B. Hebr. Zach. Cratonis Viteb. 1586 (1587), 4to.

IV. Bibl. Polyglott., Antwerp, 1569-72, fol., represent a text composed of the two last recensions. This polyglott contains in the first four volumes the Old Testament with the apocrypha interspersed. From this proceeded the Plantine Hebrew and Latin, Ant., 1571, fol.; 1584, fol.; L. B. 1673, 8vo; B. Hebr. Lat. Burg. Aurac. in Hisp., 1581, in fol.; B. Hebr. Lat., Genev., 1618, fol.; Bibl. Hebr. Lat. sumt. Fr. Knoch Fref. ad Moen., 1618, fol.; Bibl. Hebr. Lat., Vienn., 1743, 8vo; Bibl. Polyglott. Par., 1645, fol.; Bibl. Polyglotta, Lond. ed. Brian Walton, 1657, fol.; B. S. quadrilingua, accur. Christ. Reineccio, Lips., 1750, fol., and the manual editions by Reineccius, Lips., 1725, 8vo; 1739, 8vo, and 4to; 1756, 1793, 8vo.

V. Bibl. Hebr. cura et studio Eliæ Hutteri, Hamb., 1587, fol. (1588, 1596, 1603), contains a text compounded of the Venice, Paris, and Antwerp editions. Hutter's text is repeated in Hutter's Polyglotta, Nürnberg, 1591, fol. (this Polyglott was not completed), and in Nisselii B. Hebr. 1662, 8vo.

VI. Buxtorf's octavo edition, Basel, 1611, was the prototype of B. Hebr. typis Menasseh Ben Israel, sumt. Jansonii, Amst. 1639, 8vo. (The editions by Menasseh Ben Israel in 1630-31 and 1631-35 have another text.) Bibl. Rabb. Buxtorf, Bas. 1618-19; Bibl. Rabb. op. Mos. Francfurt, Amst. 1724, fol.

VII. B. Hebr. correctæ et collata cum antiquissimis et accuratissimis exemplaribus manuscriptis et hactenus impressis (cum præfat. Johannis Leusden), typis Jos. Athiae, Amst. 1661, 8vo, and 1667, 8vo. From this edition originated the following:—B. Hebr. Clodii Francf. ad Moenum, 1677, 8vo, recogn. a J. H. Majo et ultima rev. a J. Leusdeno, Francf. a M. 1692, 8vo; Biblia ad optimorum tam impressorum Clodii, Jablonskii, Opitii, quam manuscriptorum aliquot codicum fidem collata; direxit opus J. H. Majus, collat. instituit. G. Chr. Bürclein, Fref. a M. 1716, 4to; B. Hebr. ex rec. Dan. Ern. Jablonskii, Ber. 1699, 8vo, maj. This sometimes deviates from Leusden according to the authority of manuscripts and the cardinal editions, namely, Bombergiana, Venet. Regia, Basileensis Buxtorfii, Hutteriana, Menassis, ed. 2, Berlin, 1772, 12mo. After this B. Hebr. J. H. Michaelis, Hal. M. 1720, 8vo, maj. Cardinal editions are those "quæ reliquarum quasi cardinales videbantur," the authority of which was followed by others. After Athias also B. Hebr. stud. et op. Henr. Opitii Kil. 1709, 4to; and after this

Bibl. Hebr. Züllich, 1741, 4to. B. Hebr. Ever. van der Hooght, Amst. et Ultraject. 1705, 8vo, is a reprint of Athias's edition of 1667. Van der Hooght's reprint is famous for its accuracy. After this B. Hebr. Sal. Ben Jos. Proops or Props, Amst. 1724, 8vo; B. Hebr. Lat. (c. vers. Seb. Schmidti), Lips. 1740, 4to; B. Hebr. Lat. Car. Fr. Houbigant, Paris, 1753, 4 vols. fol.; B. Hebr. Jo. Simonis Hal. 1752, 8vo, 1767, 8vo; Biblia Hebr. Benj. Kennicot. Oxon. 1776-80, fol. (See Bruns de Mendis typographicis editionis Van der Hooght, a Kennicoto non sublatis in Eichhorn's Rep. xii. 225, seq.) Van der Hooght's Bible has been frequently reprinted in London. Editio nova, recognita et emendata a Josepho Samuele Frey, Typis Societatis ad promovendam Christianitatem inter Judæos, Lond. 1812, 8vo; B. Hebr. ad ed. Hooghthianam adornata, Lond. typis et sumptibus Sam. Bagster, 1823. In stereotype, Recognita et emendata a Judah d'Allemand, Typis A. Macintosh, impensis Jacobi Duncan, 1823, 1825, large 8vo; duodecimo with Hebrew title, 1825; large 8vo, reprinted 1828, 1830, corrected by Hurwitz, 1833. The most beautiful type is employed in the Biblia Hebraica secundum editiones Jos. Athias, Jo. Leusden, Jo. Simonis aliorumque imprimis Everardi van der Hooght, recensuit Augustus Hahn, Theol. Doctor et Professor in Acad. Lipsiensi, editio stereotypa sumptibus Caroli Tauchnitz, 1831, 8vo, and in 12mo, 1833.

VIII. Vetus et Novum Testamentum, ex antiquissimo Codice Vaticano, edited by Cardinal Angelo Mai, published at Rome in 1858, in 5 vols. fol.

IX. Vetus Testamentum Græce juxta LXX. ed. by Dr. C. Tischendorf, 2 vols. 8vo, Leipz. 1850. This is a collation of the Vatican text with all the recently discovered codices.

X. Biblia Polyglotta. Hebrew, Greek, Latin, and German, ed. by Dr. Stier and Dr. Theile, 6 vols. royal 8vo, Bielef. 1850-55.

The following is a list of the critical apparatuses by which the text has been purified:—The great and the small Masora, and various readings in the rabbinical Bibles of Bomberg and Buxtorf. Selections of various readings in the editions of Münster, Van der Hooght, and in the *מנחת שי*, with the critical commentary of R. Sal Norzi, Mantua, 1742-44, 4 vols.; C. F. Houbigant *Notæ criticae in univ. V. T. libros cum Hebraice tum Græce scriptos cum integris ejusdem Prolegomenis ad Exemplar Parisiense denuo recusæ*, tom. i. ii. Francf. a M. 1777, 4to. Comp. J. D. Michaelis *Vorrede, zum kritischen Collegio über die drei wichtigsten Psalmen von Christo*; J. Chr. Kallii *Prodr. examinis criseos Houbigantianæ in Cod. Hebr. Hafniae*, 1763, 4to; Ej. *Examen cris. Houbig. in Cod. Hebr. spec. i. Hafn. 1764, 4to*; Seb. Rau *Exercitationes phil. ad Houbigant. Prolegomena*, 1785, 4to; Kennicott's *Dissertations on the Hebrew text and his Bible*. Com. Bruns de variis lectionibus Bibl. Kennicot. in Eichhorn's *Repertorium* xii. 242, seq. xiii. 31, seq.; Bruns *Apologie für Kennicot* in Eichhorn's *Rep.* vi. 173, seq.; Rosenmüller's *Handbuch*, i. 241, seq.; Bibl. Reineccii ed. J. Chr. Doderlein et J. H. Meisner, Lips. 1793, 8vo; B. Hebr. dig. et grav. lectionum varietatem adjecit J. Jahn, Viennæ, 1807, 3 volumes, 8vo. Biblia Hebraica without points, after the text of Kennicott, with the chief various readings selected from his collation of Hebrew manuscripts,

from that of De Rossi, and from the ancient versions, accompanied with English notes, critical, philological, and explanatory, selected from English and foreign critics by B. Boothroyd, in two volumes, 4to, Pontefract, without the date.

Besides those in the editions of Kennicott, Jahn, &c., we notice the following collections of various readings: *מסורה סיוג לתורה ספר*, by Rabbi Meir Hallevi, Berlin, 1761; *שתי ידות* printed in Ven. 1618, and inaccurately, Amst. 1558. *Commentatio critica sistens duorum codicum manuscriptorum Biblia Hebr. continentium quis Regiomonti Borussorum asservantur cum præcipuarum variantium lectionum sylloge*, auctore D. Theod. Christ. Lilienthal. Regiomonti et Lipsiæ, 1770, 8vo. The most important work of this kind is by J. B. De Rossi; *Varie Lectiones Vet. Test. ex immensa Manuscriptorum editorumque codicum congerie haustæ et ad Samaritanum textum, vetustissimas versiones, et accuratiores sacræ criticæ fontes ac leges examinatæ*, Parmæ, 1784-88; iv. volumina 4to. maj.; and *Scholia crit. in V. T. libros, seu supplementa ad varias sacri textus lectiones*, Parmæ, 1798.

Besides the Polyglotts mentioned above, there was the Paris Polyglott of 1645; and the London Polyglott, edited by Brian Walton; and Mr. Bagster's of 1831, which contains in one folio volume the Hebrew text, the Samaritan Pentateuch, the Septuagint, the Vulgate, and the Syriac versions, for the Old Testament; and for the New, the Greek text of Mill, with Luther's German translation of the Bible, Ostervald's French, Diodati's Italian, Scio's Spanish, and that of the English authorised version. Since the first publication of these, there have been several editions, and some varieties of form.

Among the oldest manuscripts, nearly 1500 in number, which have been collated, is the Laudianus in the Bodleian Library at Oxford, which is considered to be 800 years old: this MS. differs in 14,000 readings from Van der Hooght's text, which is now in common use. Besides this there are many important MSS. at Oxford and in the British Museum in London, one in the library of the Royal Society, one in the Lambeth Library, and one MS. of the Pentateuch in the library of the London University. In the seventh and the following volumes of the 'Classical Journal' is a catalogue of MSS. existing in the public libraries of Great Britain, and a very complete list of Hebrew MSS. is prefixed to De Rossi's 'Varie Lectiones': less complete in Kennicott's 'Disertatio Præliminaris.'

These codices are known among critics by names like the following: Carlsruhensis, Viennensis, Cesenæ, in the Malatesta Library at Bologna, Florentinus 2, Mediolanensis 9, Norimbergensis 4, Parisiensis 27, Regiomontanus 2, Parisiensis 24.

A fac-simile of Deut. iv. 1, 2, from an ancient Hebrew MS. of the Pentateuch, called by the Rev. H. Horne *Codex Malabaricus*, may serve to illustrate the appearance of these codices; it was brought in the year 1806 from the interior of Malayala by the late Rev. Claudius Buchanan, D.D., and is now preserved in the public library of the University of Cambridge.

ועתה ישראל שמע אל הקים ואל המשפטים
אשר אנכי מצוה אתכם לעשות למען תחיו
וכאתם וידעתם את הארץ אשר יהוה אלהי
אבותיכם נתן לכם לאתקמנו על הדבר אשר
אנכי מצוה אתכם ולתת דעו ממנו לשמר

It measures forty-eight feet in length. The whole book of Leviticus and the greater part of Deuteronomy are wanting. The original length was about ninety feet. Its breadth is about twenty-two inches, or a Jewish cubit. It seems to comprise the fragments of three different rolls. See a 'Collation of an Indian copy of the Pentateuch,' also a collation and description of a manuscript roll of the book of Esther from the Hebrew extant in brazen tablets at Goa, with an English translation, by Thomas Yeates, Cambridge, 1812, 4to. None of the Hebrew manuscripts is above 800 years old. The reason why the manuscripts of the Old Testament are never found of so high antiquity

as the oldest of the New Testament, is that the Jews never suffer their holy manuscripts to exist in a dilapidated state. The manuscripts which begin to be illegible, or contain readings not authorised by the Masora, or are inaccurate, are collected in the *בִּנְיָן*, that is, place of deposit, or rather hiding-place, in the synagogue. When this place is filled up, all its contents are removed to be buried in a place of the burying-ground chosen for that purpose. The following line may represent a codex about to be buried for being faulty and illegible.

למלויא איש זאת שהיה ליום וישראלים

The unwearied application of the learned in the collation of Hebrew manuscripts has proved that all of them represent nearly the same text that was in the hands of the old translators, which has not suffered

any very material alteration in spite of thousands of small changes. This is also proved by the fact that the peculiarities of style which characterise the different biblical writers, have not been effaced. The

old school of the Buxtorfs and their followers believed in the general correctness of the Masoretic text. The correctness of this opinion, however, has been established, not by the opposition of the old school to critical examination, but by the exertions of those critics who for some time overrated the authority of the Samaritan Pentateuch and that of the ancient translations, and overstated the faults of the Masoretic text.

Critics now distinguish, 1st, the text before the conclusion of the canon in the parallel passages of the Old Testament; 2nd, the text before the Masora in the quotations of the Talmud; 3rd, the Samaritan and Alexandrine; 4th, the Masoretic.

The first Samaritan MSS. were brought into Europe in the year of our Lord 1620. Achill. Harlay de Sancy directed Pietro della Valle in 1616 to purchase them at Damascus, and presented them to the library of the Oratorium at Paris. There are extant, besides these, a Codex Cottonianus, a Codex S. Genov. at Paris. Compare also the Barberini Triglotta and the Paris and London Polyglotts in Samaritan types, and the Pent. Hebræo-Samarit. ed. Benj. Blayney, Oxon. 1790, in the usual square characters. [SAMARITANS.]

The earliest translations of the Old Testament were made from a text which belongs to a period from which no manuscripts have been preserved. These translations confirm the significations which are given in our Lexicons to Hebrew words, and show how the biblical text was understood at a period when the original language was still living, or when, at least, many helps to its understanding, which have since disappeared, were still accessible. We shall treat in separate articles on the following most important ancient translations:—

The Septuagint is written in the Hellenistic or Jewish Greek language, and was formerly read in many synagogues. Josephus makes more use of the Septuagint than of the Hebrew text; but at a later period, when Christians employed the Septuagint, the Jews rejected it. The Talmud appoints a fast-day on the eighth day of Tebeth, because "on that day the law was written in Greek through King Ptolemy, and darkness came over the earth for three days; and that day was fatal to Israel as the day on which the calf was made." ('Megillath Taanith,' fol. 50, c. 2 ed. Bas. 1758; 'Tract. Sopher.' ci.)

The fragments which have been preserved of the translation made by the Jewish proselyte, Aquila of Sinope, at the commencement of the second century, are very valuable, because they are so literal that they exactly represent the text which was before the eye of the translator. [AQUILA.] Theodotion only remodelled the Septuagint. His translation of Daniel was used among the Christians instead of the Septuagint. Symmachus wrote better Greek, but translated more freely. Each of these three translated with more accuracy than the translators of the Septuagint.

There are, besides, fragments of three anonymous Greek translations, which have been called, from the places which they occupy in the 'Hexapla' of Origen, Quinta, Sexta, Septima.

Parts of the Old Testament have been translated into a Jewish modern Greek, of which 'Wolfii Bibliotheca Hebræa,' vol. iii. Appendix, and vol. iv. p. 1219-26, contains curious specimens printed in Hebrew type.

According to Origen, Lucianus and Hesychius bestowed their critical labours upon the text of the Septuagint; and their editions came into public use, but have entirely disappeared. It appears from Georg. Syncell. Chronogr. p. 203, that the labours of Basilus the Great on the Septuagint consisted in his care to obtain correct copies.

In the days of St. Augustine, several Latin translations existed: among these he preferred the Itala, which was in more general use, and which had originated in the first period of Christianity. The fragments of the Itala still extant prove that it was made from the Septuagint. Hieronymus corrected it about the year A.D. 382; but the greater part of his labours was lost during his own lifetime, and he could not gratify the desire of Augustine to restore the loss, because he had not sufficient scribes at his command.

According to Abulfaragius, the Syrians had, along with the Peschito, another translation of the Septuagint, which has been called, according to an erroneous reading of Pococke, the Figurata.

Of the Syrian translation by Philoxenus, bishop of Hierapolis, we know so little that we cannot say whether it was the same with the Figurata.

In the Ambrosian library at Milan there are the Psalms, Job, Proverbs, Ecclesiastes, Song of Songs, the Wisdom of Solomon, Sirach, the twelve minor prophets, Jeremiah, Baruch, Lamentations, Daniel, Ezekiel, and Isaiah, in an Hexaplar Syriac translation by Paul, bishop of Tella, of the year 616. Of the same translation there is a copy at Paris of the fourth, or, as we call it, the second book of Kings. This version was translated into Arabic by Hareth Ben Senan, A.D. 1486, and is preserved in the Arabic at Paris and at Oxford.

The Ethiopians have, in the Geez, an anonymous translation of the whole Bible, the origin of which cannot be earlier than the 4th century. This version was made by Christians from the Alexandrine Greek translation, but it is now used by Jews also. Of this there are several complete manuscript copies in Europe, a list of which is given by Ludolf: parts of it have been printed. Other copies have been brought to Europe by Bruce and Rüppell.

There exists also a translation in the dialect of Lower Egypt, the so-called Coptic or Memphitic; and another in the dialect of Upper

Egypt, the Sahidic, or Thebaic. The origin of these translations, parts of which have been printed, belongs probably to the end of the 3rd, or the commencement of the 4th century. Both were made from the Septuagint.

The Armenian translation by Miesrob was executed with the assistance of Johannes Ekelensis and Jos. Palnensis, about A.D. 410. With this translation, Miesrob gave to the Armenians an alphabet. He followed the Septuagint, and in Daniel the Greek of Theodotion. Miesrob's translation is said to have been interpolated in the 6th century according to the Peschito, and in the 13th century according to the Vulgate.

The Georgian or Grusingian translation was made in the 6th century, and follows the Septuagint.

The Slavonic translation is said to have been made in the 9th century, from the text of the Septuagint; but, according to Alter, it originated from the Itala, and was altered in the 14th century according to Greek MSS.

It is unnecessary, in an article so limited as the present, to do more than name the Arabic translations, the Veneta, the Targumim, the Samaritan translation, the Peschito, the Vulgate, the Gothic, the Anglo-Saxon, and Persian translations, &c.

The Hebrews had, like other nations, their prose and poetical styles. The poetical style is distinguished by great boldness and freshness of expression, and by a rhythmical movement or cadence of language. This rhythmus occurs in various degrees. There are parts in the prophets, and in the book of Ecclesiastes, which are scarcely elevated above the level of prose. The gradual ascent from prose to rhythmus, and the descent from rhythmus to prose, constitutes one of the beautiful characteristics of Hebrew poetry. The rhythmus of syllables is, in Hebrew, so free, that some have preferred to call it "numerus by accentuation." This numerus consists usually in a free mixture of iambics, trochees, amphibrachs, and anapaests.

"The books and passages of the Old Testament, which are composed in a poetical style, have such a diversity of character, from the various times at which they were written, that it is necessary to distinguish them into several periods. Four of these periodical divisions may be conveniently adopted.

"The first embraces short historical songs, and oracular sentences: simplicity and obscure brevity are the characteristics of these. The second era is that of heroic song. In the times of the Judges, the actions of the protectors and defenders of Israel were celebrated in this style. Of the same description are inspiring war-songs, and songs of triumph. The third period commences with the schools of the prophets, founded by Samuel, in which the art of poetry was enlarged, refined, and ennobled. Historical poems, pastorals, and hymns in praise of God, and war-songs, were produced by these schools. At length, under David and Solomon's reign, we approach the golden age of Hebrew poetry, to which succeeded the sublime oracles of the prophets. They uttered, in solemn strains, promises and threatenings, and described better times to come, in imagery borrowed from the golden age. The fourth epoch coincides with the time about and subsequent to the Babylonian captivity. Then the fiery energy of the prophetic poetry was lost, and plaintive songs of woe were blended alternately with joyful strains, sung in hope of their return to Zion, and with cheerful festive hymns, in which the expectation of a universal kingdom of God on earth was expressed in various ways.

"With respect to the external form, the various species of Hebrew poetry may, upon the whole, be described by the names given to their poetic compositions by the Greeks and Romans; but it must not be imagined that their arrangement and disposition are of the same kind. The following may be considered as distinct species of Hebrew poetry:—

"First, short traditional poems, containing anecdotes of families, for the purpose of handing them down to posterity. Second, longer historico-religious poems; as, for example, 1 Moses (Gen.) i. and ii., also Psalms cxxxv. cxxxvi.; and poems of a mythic form, 1 Moses (Gen.) iii. xi. Third, odes: these are subdivided into—1, Hymns, songs of praise and thanksgiving, for divine worship; 2, Common odes, in which other important objects were expressed in sublime imagery; and, finally, 3, War-songs, which often ascend to the dignity of the ode. Fourth, elegies, lamentations, pastoral lays, and songs in praise of love. Fifth, songs of a middle species, which do not attain the character of the ode. Sixth, didactic poems, of which there are—1, Many short ones in the Psalms; and, 2, Some of greater length in Job and Ecclesiastes. To these latter belong—3, Parables, fables, and allegories; and, finally—4, Single sententious apophthegms, or proverbs.

"Descriptions of the separate prophetic books are given in the Introductions (such as those of Eichhorn, Jahn, Berthold, and De Wette) to the Old Testament: but those books must be divided into two classes, in order to facilitate their interpretation, namely, those written before, and those written after the captivity, as the character and contents of the latter differ materially from those of the former writings.

"The first period of those writings is that between Moses and the captivity. The prophets who lived in this period laboured to oppose idolatry; and continually exercised this grand theme of their discourses and denunciations in new forms, and under various images and conceptions. They announced on these occasions the approach of

divine justice in the devastation of the land, and the carrying off of its inhabitants, but they at the same time opened a view into a distant state of future felicity, the return of the better part of the Israelites to the true God, the return of many of themselves out of all tribes to Judæa, and their re-union as a people. They already saw many heathens, proceeding with the Jews towards Jerusalem, for the observance of the same worship; they saw a divine kingdom, whose borders were to be continually enlarging.

"The other period is that from the exile to Malachi. The prophets who lived during this time sustained the hopes of Israel; but they at the same time directed their exhortations to the promotion of the true worship of God, and denounced punishment against hypocritical offerings, against indolence in doing good, against unrighteousness, and many other sins, as being the cause of preventing God from fulfilling, in their complete extent, his promises to the citizens of the newly-restored Jerusalem. Some of the prophets already foresaw a time of severe judicial punishments to be inflicted by God on the refractory Israelites." (Seiler's 'Hermeneutics'.)

The English Bible.—No complete translation appears to have been made in the Saxon times into the language then spoken in England. By some writers Bede is said to have made such a translation, but this is now generally understood to be a mistake. That he translated portions of the Scriptures is, however, certain. One of the best authenticated facts in his life is, that he was employed in translating the Gospel of St. John into Saxon at the time of his decease. The early writers who relate this fact differ respecting the extent to which he had proceeded in translating this Gospel. No evidence can be produced that the whole of the Scriptures was, by any person, rendered into Saxon. But of the more important portions Saxon versions still exist in manuscript. We shall notice three of the most remarkable copies:—1. A manuscript of the Psalms in Latin, with an interlinear Saxon version. This is now in the Cottonian Library at the British Museum, where it is numerated Vespasian A. i. 2. A manuscript of the Gospels in the same library, numerated Nero D. iv. This contains the Latin text, with an interlinear Saxon version. Both these manuscripts are of singular beauty, and impress the mind with a strong feeling of respect for the monks of Lindisfarne, in whose house, and probably not later than the 8th century, they were executed. 3. Another manuscript of the same class is at Oxford, where it is known by the name of the Rushworth Gloss, on account of its having belonged to Rushworth the historical writer. This manuscript contains the Gospels only. Other manuscripts exist of Saxon versions of portions of the Scriptures in many libraries; and there are notices in writers on Saxon affairs of several persons who, beside Bede, were employed in the translation of these important writings into the vernacular tongue. At the Reformation, when the work of translating the Scriptures met with opposition from the church, it was a point of some importance to draw the public attention to the fact that versions into the vernacular tongue were no novelties in England. It was with this view that Parker, archbishop of Canterbury, encouraged Fox, the writer of the Martyrology, to prepare an edition of the Gospels in Saxon, which he did, and published it in 1571. Another edition, the result of the collation of a greater number of manuscripts, was published in 1638, and again in 1665. This was the joint work of Junius and Marshall. They gave at the same time the text of Ulphilas's version, into the language called the Mæso-Gothic, a kindred, perhaps the parent, language of the Saxon.

Devout persons seem to have employed themselves in rendering portions of the Scriptures into the language spoken in this country, when what we call Saxon was becoming what we now call English. It is thought that the whole of the Scriptures had been translated in the 13th century. It is, however, certain that in the 14th century, not single and separate portions only were translated, but the whole of the books comprehended in the Sacred Canon, and that they were put together in order as they were found in the Latin originals so as to form a volume answering to what we mean when we speak of the Bible. There are two persons, both of the age of King Edward III., who are said to have executed this work. The one, John de Trevisa, a native of Cornwall, was educated at Oxford. He translated the work of Bartholomeus, 'De Proprietatibus Rerum,' and the 'Polychronicon' of Higden—the one the most popular book in the philosophy of the age, the other in the history. Caxton, writing not a century after the time, says that he also translated the Holy Scriptures, but this is now matter of uncertainty. But there is no doubt that Wycliffe did translate the whole Bible, or gathered together translations which made an English Bible. Many copies of this volume were made about the time when it was completed, which was about a century before the introduction of printing into England. Wycliffe died in 1384.

Wycliffe's version of the Scriptures is deeply interesting, on account of the circumstances under which it was produced, and its connection with a favourite English name. It is of some importance in Biblical literature, as showing what Latin version was in his time regarded as of the highest authority in England, and also in what light certain questions in theology were viewed by that early Reformer. It is also curious as a monument of the state of the language in the middle of the 14th century. It was republished in 1850, under the editorial care of the Rev. Josiah Forshall and Sir Frederick Madden. The New Testament from this version was published by John Lewis, a clergy-

man of Margate, in 1731, reprinted under the care of Mr. Baber of the British Museum, in 1810; and in 1850, again printed from a contemporary MS. formerly in the monastery of Sion, Middlesex.

From the time of Wycliffe the authorities in the English church did whatever they could to discountenance the circulation of the Scriptures in the ordinary language of the people. It was regarded as a measure which was likely to produce heresies, and as a work which could never be executed with a sufficient degree of exactness. The time was, however, approaching when an opposition which was irresistible would be made to the church in this point.

It is to the resistance which was made by the ecclesiastical authorities of the time that we are to attribute the remarkable fact that, though the art of printing was introduced into England in or about 1474, yet no English Bible or Testament was printed till 1526, and then at a foreign press.

To William Tyndal we owe a translation of a large portion of the Scriptures into the English tongue, next in antiquity to Wycliffe's. Tyndal was acquainted with Luther, whose advice and assistance he is reported to have had in his translation. He lived much abroad, and before 1526 he had completed an English version of the New Testament. Of this he printed in that year two distinct editions; one in quarto at Cologne, another in duodecimo at Antwerp. Perfect copies of either of these editions are not known. The few imperfect copies which exist of this, the 'Editio Princeps' of the English New Testament, and very few they are, are treasured as the choicest book curiosities. Tyndal proceeded in his work of translation, and not less vigorously in superintending successive editions of his New Testament through the press. They were bought up and burnt in England; but this only supplied him with the means of printing other editions with such corrections and improvements as were suggested to him. He is said to have also printed a translation of the Pentateuch, and it is certain that he did translate those five books of Moses, and also many other books of the Old Testament. He did not, however, commit to the press any complete translation of the whole Scriptures. Tyndal was put to a cruel death at Filford, near Antwerp, where his translation first appeared in 1526. A reprint of this was issued at Andover in Massachusetts, U. S., in 1837, with the variations of Coverdale's, Matthew's, Cranmer's, the Geneva, and the Bishop's bibles.

Another person who at that early period engaged in the work was Miles Coverdale, a friend of Tyndal. He produced a complete English Bible, composed of Tyndal's translations, as far as they went, and his own. This was the first edition of the Bible in English. It was followed by several other publications of the English Bible in the interval between 1535 and 1611, when the present authorised version was first published. Of these we shall give a catalogue of the most remarkable, observing generally, that of each of these there were several distinct re-impressions, and of some of them many.

1. *Coverdale's Bible.*—This was printed at Zürich, it is believed, in 1535, and dedicated by Coverdale to Henry VIII. It was favourably received by the court. In the next year, Cromwell, the king's vicar-general and vice-gerent in ecclesiastical matters, enjoined that a copy of this translation should be laid in the choir of every parish church in England, for every one to read at his pleasure. A reprint of this was published in 1838, and again in 1847, with a memoir of Coverdale.

2. *Matthew's Bible.*—This also was printed abroad, but at the expense of two English printers, Grafton and Whitchurch: the date is 1537. The name of Thomas Matthew, whose edition it was said to be, is feigned. The real editor was John Rogers, the first person burned for heresy in the reign of Mary. The text is that of Tyndal and Coverdale slightly altered.

3. *The Great Bible, or Cranmer's.*—The Bibles hitherto published had been but the work of private persons. Cranmer, who was at that time archbishop of Canterbury, had, from the time when Coverdale's Bible appeared, been anxious to engage the bishops in the preparation of an English Bible, which should go to the people under their express authority. He found them not very eager to engage in the design. It is supposed that Coverdale had much to do in the preparation of this edition. The text is, in the main, the same with his. The preface was written by Cranmer. It was finished at the press of Grafton and Whitchurch in April, 1539.

4. *Taverner's Bible.*—This also appeared in 1539. The editor was Richard Taverner. The text is formed on that of Matthew's Bible.

There were eleven impressions of the English Bible in the reign of Edward VI., but they are considered as only reimpressions of one or other of the editions above mentioned.

5. *The Geneva Bible.*—During the reign of Mary, some of the divines who had been the most forward in promoting the Reformation took refuge at Geneva. Among these was Coverdale, who seems to have regarded the diffusing of the Holy Scriptures in the English tongue as his peculiar province in the labour of reformation. He and some other of the Protestant exiles, especially Gilby and Whittingham, set themselves to prepare another edition, to be accompanied with notes. They were employed in seeing it through the press when the death of Mary and the accession of Elizabeth opened a way for their return. Some remained behind to finish the work, which appeared in 1557. This long continued to be the favourite Bible of the English Puritans and of the Scotch Presbyterians. Not fewer than fifty impressions of it are known, and there were probably more. Both in the text and notes

there is a great leaning to the system of Calvin and Beza, with whom the exiles at Geneva were intimately acquainted. It scarcely deserves to be mentioned that this edition is often called the 'Breeches Bible,' on account of a rendering given in Genesis iii. 7.

6. *The Bishop's Bible, or Parker's*, so called from Matthew Parker, archbishop of Canterbury, first appeared in a large folio in 1568. Parker employed learned men to review the previous translations, and compare them with the originals. This edition exhibits, in consequence, some material variations.

7. *The Douay Bible*, of which the New Testament was first printed at Rheims in 1582, and the Old Testament at Douay in 1609-10. This is the Roman Catholic version. Cardinal Allen is understood to have had a principal share in this work.

This brings us to the period of King James's translation. Early in the reign of King James I. there was a conference of divines of different opinions at Hampton Court, for the settling the peace of the Church. In this conference much was said concerning the imperfections of the existing translations of the Scriptures. The king himself, who was often present at these meetings, expressed a strong opinion on that point of the debate. "I wish," said he, "some special pains were taken for a uniform translation, which should be done by the best learned in both universities, then reviewed by the bishops, presented to the privy council, and, lastly, ratified by royal authority, to be read in the whole church, and no other." Out of this speech of the king's arose the present English Bible; for the suggestion soon ripened into a resolution. As this is the Bible which has now for more than two centuries been the only Bible allowed to be read in the English Church, and as it is also the Bible universally used in dissenting communities, we may be expected to give a more extended notice of it than of the former editions. Fifty-four of the persons in that age most distinguished for that particular species of learning which such a duty required, were selected for the work, according to the king's suggestion: finally, forty-seven of them undertook it. They divided themselves into six independent classes, to each of which a certain portion of the work was assigned. Each person in the class was to produce his own translation of the whole committed to them: these several translations were to be revised at a general meeting of the class. When the class had agreed upon their version, it was to be transmitted to each of the other classes, so that no part was to come out without the sanction of the whole body.

Two of the classes sat at Westminster, two at Oxford, and two at Cambridge. The instructions which they received from the king were, that they should adhere to the Bishop's Bible, which was then ordinarily read in the churches, making as few deviations from it as possible. They were, however, to use the other versions, and to consult the translations which had been made into other modern languages; and they were to keep in the old ecclesiastical words, such as church, &c. When a word had divers significations, "that should be kept which had been most commonly used by the ancient fathers, being agreeable to the propriety of the place, and the analogy of faith." No marginal notes were to be used, except for the further explication of some Greek or Hebrew word. References to parallel passages might be given. They were to call in the assistance of any learned man who was known to have made the subject his study.

They were employed upon the work for three years, namely, from 1607 to 1610; proceeding with that deliberation and care which so weighty an undertaking required. The names of the divines engaged in it (and the portions are known which were committed to each class) are preserved. If we say that there are few names among them which have acquired a lasting celebrity, we are only saying of them what is the usual fate of divines. The name of Bishop Andrews is the first in place and first in celebrity. It is believed that Bancroft, then archbishop of Canterbury, though not one of the professed translators, had much to do in the superintendence of the work. It came forth from the press of Robert Barker in 1611.

This is then the great era in the history of the English Bible. From that time to the present there has been no serious intention entertained in the Church of any revision of this translation. It is admitted universally that it is in the main an admirable translation. But many persons in the Church have thought that, excellent as it confessedly is, it is not the best possible translation; and that it seems as if the time was arrived for revising the work of the divines of the days of King James, especially since the general principles of translation seem now to be better understood than heretofore, and the investigations of men of learning in the manuscripts of both the Old and New Testament in the originals have led to the establishment of a text which is allowed to make a nearer approach to the text as left by the original writers, than that which was used by King James's translators.

While, however, nothing has been done by authority, many persons have produced new and, as they presume, improved translations of particular books. Dr. Geddes, a Roman Catholic divine, but who had no particular attachment to his Church to influence him in his version, published a translation of the historical books of the Old Testament; and a translation of the Old Testament from the Septuagint version according to the Vatican text, with various readings from the Alexandrian copy, was published in 1842, by Sir L. C. L. Brenton. Lowth, bishop of London, and Dodson a learned layman, both published translations of the prophecy of Isaiah; Blayney, a translation of

the minor prophets; Stock, an Irish bishop, of the book of Job. Other translations of other books of the Old Testament have appeared, nor have there been wanting those who have attempted the too arduous task of translating the whole of these books. Numerous translations have been published of the New Testament, of which we may mention that by Gilbert Wakefield, and that by Newcome, the archbishop of Armagh. A new edition of the Greek text, with valuable notes, was published in 1854 by the Rev. H. Alford, who has since published translations of the Gospel according to St. John and Paul's Epistle to the Romans.

Still more numerous have been the editions of the English Bible in the version of King James, with notes, paraphrases, and practical expositions. Our limits will not allow of our entering upon an enumeration of these works. We must, however, name as works which are highly esteemed, Matthew Henry's 'Exposition of the Old and New Testament,' which originally appeared in 5 vols. folio, and has been often reprinted; the Family Bible, prepared by the Rev. Thomas Scott, rector of Aston-Sandford, in Buckinghamshire, a clergyman of what are called evangelical sentiments; the Commentary on the Bible by Adam Clarke, LL.D., a leading minister among the Wesleyan Methodists; the Family Bible of the Rev. Charles Wellbeloved, of York, a Presbyterian minister of Unitarian sentiments; and the 'Pictorial Bible,' with the commentary and illustrations by Dr. Kitto.

Modern translations into a vast variety of languages have been made, either of parts or the whole of the Old and New Testaments, which will be noticed under BIBLE SOCIETIES, by the exertions of which they have been chiefly effected.

BIBLE SOCIETIES. Associations, supported by voluntary contributions, for the general circulation of copies of the Sacred Scriptures, may be regarded as belonging peculiarly to the present century. Whatever had previously been done, either by societies or individuals, in the way of translating or printing the Bible, is insignificant when compared with what has been done since 1804. Previous to the formation of the British and Foreign Bible Society, the associations in Great Britain which included among their objects the circulation of the Bible were:—

1. The Society for the Propagation of the Gospel in New England, originally incorporated by an ordinance of parliament in 1649, and re-incorporated in 1661, after the Restoration. The missionary Eliot, known as the Apostle of the American Indians, after labouring to reduce the language of the tribes then surrounding the infant colony to writing, effected a translation of the Bible into it, which was printed in 1663 at the expense of the corporation. This edition of the Bible, which is dedicated to Charles II., contains the Psalms of David, attempted to be done into Indian metre, which Cotton Mather tells us were used in the congregations of the converted natives.

2. The Society for Promoting Christian Knowledge, established in 1698. It had caused an edition of the New Testament to be printed in Arabic, the whole of the Scriptures in Manx, and four editions of the Scriptures in the Welsh language.

3. The Society for the Propagation of the Gospel in Foreign Parts, established 1701. This and the preceding institutions were under the entire management of members of the Established Church.

4. The Society in Scotland for Propagating Christian Knowledge, incorporated in 1709. It distributed the Scriptures in Gaelic.

5. The Society for Promoting Religious Knowledge among the Poor, established 1750. The subscribers were entitled once in two years to copies of the Scriptures or other works published by the society, at a reduced charge.

6. The Bible Society, established in 1780, for the purpose of circulating the Scriptures among soldiers and sailors exclusively. In about twenty years it had distributed about 30,000 copies.

7. The Society for the Support and Encouragement of Sunday Schools, established in 1785. It provided the Sunday schools with copies of the Bible and Testament, and with spelling-books.

8. The French Bible Society, established in London in 1792, for the purpose of distributing copies of the Scriptures in France. This institution had made arrangements with a printer for an edition of the Scriptures in the French language, when its operations were entirely stopped by the Revolution. At the peace of Amiens it was discovered that the printer with whom the contract had been made, and who had received a sum of money on the society's account, had been ruined in the interval, and was unable to complete his engagements.

Such were the means in existence previous to the close of the last century for ensuring the general circulation of the Scriptures.

The most important of the above associations, in fact the only one which could attempt the circulation of the Bible on a large scale, was the Society for Promoting Christian Knowledge. Its efforts, however, do not appear to have been commensurate with the increasing demand. The following statement attributes to a tardiness in its operations the formation of the British and Foreign Bible Society:—

In 1787 a clergyman in London, who had been applied to for Bibles by a brother clergyman in Wales, wrote to the latter, stating that he had received twenty-five copies from the society for distributing Bibles among the soldiers and sailors; and that he was collecting money to send more, which he bought of the Society for Promoting Christian Knowledge, "who alone in London have got any Welsh Bibles." A year afterwards the same individual wrote to his corre-

spondent in Wales, stating that "there was a prospect of obtaining, through the assistance of another society, and with the help of Mr. T.'s purse, no less a number than 1000 Welsh Bibles; but the society, namely, the Society for Promoting Christian Knowledge, refuses to part with more than 500, and that at a price which altogether makes 5s. 6d. each. This has entirely defeated the design, so far as I am concerned in it."

Towards the close of 1791, a clergyman who had been visiting Wales alluded, on his return to London, to the scarcity of Bibles: "I heard great complaining amongst the poor for want of Bibles, and that there were none to be had for money." A fresh series of efforts was made in order to induce the Society for Promoting Christian Knowledge to publish another edition of the Welsh Bible; and a correspondence was entered into with the society, which may be seen in Dealtry's 'Vindication of the British and Foreign Bible Society.' The object of this correspondence was to induce the society to undertake an edition of 10,000 Bibles for circulation amongst the Welsh, and the applicants expressed their willingness "to take and pay for 5000 as soon as they were printed." At length, in July, 1792, terms were agreed upon with the society, and the wishes for a supply of Bibles seemed on the point of fulfilment. On the 29th of October, however, the individual who had conducted the negotiations with the society complained of its "dilatatory, indecisive, and reluctant" conduct. The society could not be made to believe that "a large number of Bibles could be got off;" it seemed averse to incur the expense of a supply, although not likely to be more than from 1500*l.* to 2000*l.* In fine, the society surrounded the subject with so many difficulties that for the present it was reluctantly abandoned.

At length, in 1796, after an interval of about four years, during which, it may be presumed, the society continued to be urged on the point, an edition of the Welsh Bible, Common Prayer, and Singing Psalms, to the amount of 10,000, with 2000 extra Testaments, was ordered to be printed. In 1799 copies were ready for delivery, and the society liberally offered them on moderate terms. The whole of the edition was soon disposed of, as thirty years had elapsed since the last edition had appeared. The wants of the principality having however only been partially satisfied, the demand for Bibles on the part of those who had not participated in the recent supply became louder than before. Application was made in the year 1800 in order to ascertain if the society were disposed to undertake another edition. In 1802 the hope of engaging the society to enlarge the supply was abandoned. The plan of contracting for a supply of Welsh Bibles without the co-operation of the society was then agitated for the first time. It was suggested by the Rev. Thomas Charles, an ordained minister of the Established Church, but who was at the time officiating in the congregations of the Welsh Calvinistic Methodists. On the 7th of December 1802, the subject of the scarcity of Bibles in Wales having been introduced by Mr. Joseph Tarn in a circle of friends, Mr. Charles, who happened to be visiting London, and was present, proposed raising by voluntary contributions a sum sufficient for printing an edition. He insisted upon the urgency of applying to "new and extraordinary means" for effecting this purpose. In the course of the evening, the Rev. Joseph Hughes, a Baptist minister, suggested the outline of a plan for the *general* circulation of the Scriptures; and a call was made upon him to prepare an address in which the subject might be presented to public consideration. The matter was soon after laid before the late Mr. Wilberforce, Mr. Charles Grant, afterwards Lord Glenelg, and other men of like views. The Rev. C. F. A. Steinkopff, Lutheran minister at the Savoy Church in London, offered to make inquiries in the course of a Continental journey he was about to undertake, as to the circulation of the Scriptures in that quarter. A similar course was contemplated with respect to Great Britain and Ireland.

The occurrences detailed above took place prior to the end of May 1803. By this time the appeal which Mr. Hughes had been called upon to prepare was finished. Its title was, 'The Excellence of the Holy Scriptures, an Argument for their more general Diffusion.' The rudiments of the Bible Society were developed in this address, and having been extensively circulated, it was deemed, in the month of January 1804, that a sufficient period had elapsed for the discussion of its merits, and that the time had arrived for putting the plan into activity. Samuel Mills, Esq., who had prepared an outline in the preceding year, now completed the details of the plan. The projected society had at first received the name of the "Society for Promoting a more extensive Circulation of the Scriptures both at Home and Abroad;" but it was now changed to that of "The British and Foreign Bible Society."

On Wednesday, March 7th, 1804, a public meeting, convened by a circular address, was held at the London Tavern, Bishopsgate Street, to discuss the means of forming the society. The attendance consisted of about 300 individuals of various religious denominations. The first and second resolutions moved were as follow: 1. "That a society shall be formed, with this designation, the 'British and Foreign Bible Society,' of which the sole object shall be to encourage a wider diffusion of the Holy Scriptures." 2. "That this society shall add its endeavours to those employed by other societies for circulating the Scriptures through the British dominions; and shall also, according to its ability, extend its influence to other countries, whether Christian, Mahometan, or Pagan." Seven other resolutions relating to the organisation of the

society were passed unanimously. A committee was formed, 700*l.* were at once subscribed, and the institution was considered to be fairly in existence.

On the 12th of March 1804, the committee met to complete the organisation of the institution. The thirty-six individuals composing the committee comprised men of various religious opinions. It must be confessed that they were surrounded with considerable difficulties. Every step, in fact, was on delicate ground; and this was more especially manifest when an individual proposed the appointment of the Rev. Joseph Hughes to the office of secretary. This motion was opposed by the Rev. J. Owen, afterwards one of the secretaries and the historian of the Bible Society, who insisted in strong terms on "the impropriety and impolicy of constituting a dissenting minister the secretary of an institution which was designed to unite the whole body of Christians, and for which its directors had evinced so laudable an anxiety to obtain the patronage and co-operation of the Established Church." The individual who had moved Mr. Hughes's appointment, as well as the committee generally, saw the propriety of Mr. Owen's objections; but it was fortunate that the opportunity had arisen which called them forth, as they led to an arrangement, the principle of which was at once so judicious and liberal, that when acted upon, as it has been in all the movements of the society, it has constituted one of the chief corner-stones of its stability and success. It was accordingly moved, that the Rev. Josiah Pratt, B.D., the secretary to the Church Missionary Society, who had been pointed out by Mr. Owen as a fit individual, should be appointed secretary, in conjunction with the Rev. Mr. Hughes. The creation of another office was then suggested, in order that the foreign churches might be represented in the society; and the Rev. Mr. Steinkopff was appointed foreign secretary. Thus, as Mr. Owen remarks, "the progress of an hour carried the committee on from the hasty suggestions of a short-sighted attachment to the wise determination of a liberal policy." To prevent the operation of temporary feeling in the appointment of the governing body, the future proportion of Churchmen, Dissenters, and foreigners on the committee was distinctly defined. This body was to consist of thirty-six individuals, namely, six foreigners, resident in or near the metropolis, fifteen Churchmen, and fifteen Dissenters,—the whole of the thirty-six being laymen. The clergymen and ministers generally had a seat and vote on the committee on the same terms by which they became members of the society. Mr. Pratt having voluntarily resigned his office, Mr. Owen was appointed secretary in his place.

On Wednesday, May 2nd, 1804, a general meeting of the subscribers and friends of the institution took place, at which Lord Teignmouth was appointed president of the institution. On the 5th of May, the bishops of London, Durham, Exeter, and St. David's recognised the society by sending in their names as subscribers, and in June they accepted the office of vice-presidents.

Such was the formation of the British and Foreign Bible Society; and its subsequent history involves that of all similar institutions which it has called into existence in every part of the world. In Germany, as early as 1712 the Baron von Canstein instituted an establishment at Halle for the purpose of furnishing the Bible at as cheap a rate as possible: and this it did with remarkable success, its issues of complete Bibles exceeding three millions, and of the New Testament more than two millions. The first foreign Bible society was formed at Nürnberg in 1804; but the seat of its operations was afterwards transferred to Basel. This was termed the German Bible Society. In 1805 a society was established at Berlin, which afterwards, in 1814, became merged in the national institution of the Prussian Bible Society, which has now distributed more than two million copies of the Scriptures. Notwithstanding the war, which for a time would appear to have presented a formidable obstruction to the progress of such associations, the continent of Europe may be described as having become in a few years literally covered with Bible societies. In St. Petersburg the Russian Bible Society was established, not merely with the sanction, but by the formal authority of the Emperor Alexander, during the year 1813. After the accession of the Emperor Nicolas, the operations of this society, and of all its auxiliaries, amounting in number to 289, were suspended by an imperial ukase. The motives which led to this do not distinctly appear; though probably arising from the dissensions amongst the hierarchy of the Greek Church, numbers of whom viewed with jealousy the efforts which were making to disseminate the Scriptures; but permission was afterwards given to establish a *Protestant* Bible Society, for the purpose of supplying the Protestants in Russia with the Scriptures. The Russian society had however done good work, for they had caused the Bible to be translated into thirty-one languages and dialects of people living under the Russian government. A society was formed in Paris in 1818; this now exists under the title of the French Protestant Bible Society. In the report made by it on May 4, 1859, it is stated that there had been issued in the year, 13,448 volumes; that the income of the society had been 45,000 francs, a considerable increase over the preceding year; and that small pocket stereotype editions of the New Testament were being prepared for the use of soldiers and sailors.

There are at present societies or agents at Toulouse, Frankfort, Colmar, Mühlhausen, various places in Switzerland, Würtemberg, Saxony, at Warsaw, Cologne, Elberfeldt, Neuwied, Geneva, Dorpat, in Sweden, Norway, and Denmark, in Belgium, and Holland. In Spain,

Portugal, and Italy efforts have been made to introduce the Scriptures, but in 1816 a popish bull was issued forbidding the diffusion of the Bible among the people as dangerous; and in 1817 another was issued forbidding the establishment of Bible societies. In more recent years, individuals in Italy have been proceeded against, and even imprisoned, for having a Bible in their possession. In the Austrian dominions, also, in the same year (1817), the distribution of Bibles and the establishment of Bible societies were forbidden. Agents are also in Greece, and at Smyrna, Bucharest, Constantinople, Damascus, Astrachan, Selinsk, Tunis, &c., exclusive of the extensive connexions of the society throughout the British dependencies in every quarter of the world.

In the United States of America, the first society which was formed was the Philadelphia Bible Society, in 1808. This example was imitated in numerous other places of the Union; and in 1816 the idea of a general national institution was carried into execution by the establishment of the American Bible Society. There are now there upwards of 1000 establishments distinguished as ladies' societies.

It will be unnecessary to trace further the progress of the formation of other societies in different parts of the globe, the details being in all cases similar. We therefore return to the immediate history of the British and Foreign Bible Society.

The first application of the society's funds to printing the Scriptures in a foreign language took place in 1804, when 2000 copies were proposed for circulation among the Mohawk Indians. At this time the foundation was laid of a library, which has become by frequent accessions a valuable and curious collection of biblical literature. The society was very early called upon to exercise its judgment and discretion in regulating the movements which it had produced. It had adopted from the first, as a fundamental principle, the resolution of circulating only the authorised English version of the Scriptures without note or comment. The individual who proposed the Mohawk version was well known to the Indians, and thinking to prepare for the more favourable reception of the Scriptures among them, he wrote an address every way calculated to effect this purpose, which he caused to be pasted inside each copy. The society, in strict adherence to its conviction of the duty of circulating the Scriptures alone, was compelled to suppress the excellent address which had been prepared. The prudence, good sense, and moderation of the committee of the Bible Society, exercised at this period, when it might have been anticipated that it would have been anxious to awaken the enthusiasm rather than repress the zeal of its supporters, have throughout its whole career formed the most remarkable characteristics of its proceedings.

Yet notwithstanding the general care and prudence of the committee, a deviation from the strict letter of the fundamental rule, which permits only the circulation of the authorised version, raised a controversy which at one time appeared to threaten the stability of the society. About the year 1821 it began to be intimated publicly, that the committee had been in the practice of permitting the apocryphal books to be intermingled in such copies of the Scriptures as were furnished to foreign societies. The staunch friends of the authorised version *exclusively* took up the matter very warmly, especially in Scotland; the controversy was carried on with much heat and acrimony; and (a natural consequence in all such controversies) the original accusation was not allowed to stand alone. Complaints were made of mal-practices in the expenditure of the society's funds; the correctness of many of the translations of the Scriptures made under the direction of the committee was impugned; and other matters were laid to the charge of the managers of the society, all of which combined led to a secession of many auxiliary societies, and weakened for a time the authority and influence of the parent society. The committee, in 1826, brought forward the following resolutions: "1. That the fundamental law of the society, which limits its operations to the circulation of the Holy Scriptures, be fully and distinctly recognised as excluding the circulation of the Apocrypha. 2. That in conformity to the preceding resolution, no pecuniary aid can be granted to any society circulating the Apocrypha; nor, except for the purpose of being applied in conformity to the said resolution, to any individual whatever. 3. That in all cases in which grants, whether gratuitous or otherwise, of the Holy Scriptures, either in whole or in part, shall be made to any society, the books be issued bound, and on the express condition that they shall be distributed without alteration or addition." Confidence has been gradually restored since these resolutions were acted upon; and the society is now (1859) in a higher state of activity and prosperity than it has ever enjoyed since its foundation.

It would have been utterly impossible for the Bible Society to extend its operations into every corner of the globe unless its resources had been increased by the various branches into which it ramified. These branches have communicated life and energy to the parent stem from the most remote and distant quarters. The growth of societies whose operations were auxiliary to those of the original institution does not appear to have been very rapid. In March, 1805, the first Bible association was formed at Glasgow; in July, an association was formed in London; and in April, 1806, one was formed at Birmingham. These associations had not a separate and distinct existence, and possessed no independent forms of government; they were simply unions of a few individuals whose contributions were devoted to the parent society. In proportion as the system of which they formed a part

gathered power and influence, they necessarily assumed a more important character. As auxiliary societies, although still in connection with their prototype, their functions and exertions became more individual and local in their nature.*

The first auxiliary Bible society was established on the 28th of March, 1809, at Reading. It adopted the regulations of the parent society. On the 30th of the same month, auxiliary societies were established at Nottingham and Newcastle-upon-Tyne. The Edinburgh Society was established July 31; and similar institutions were formed in East Lothian, Leeds, and Exeter, on the 4th of October, 25th of October, and 8th of December, respectively. The first auxiliary institution, established in the year 1810, was at Manchester. An auxiliary Bible society was formed at Kendal on the 5th of January; one at Bristol on the 1st of February; one at Sheffield on the 5th; one at Leicester on the 19th; and the Hull Auxiliary Society was established April 4th. Eleven of these institutions had been established previous to the sixth anniversary of the parent society. The public nature of the proceedings connected with the establishment of these societies occasioned the claims and merits of the institution to be much more generally known and acknowledged: and the formal recognition of its value and importance, made by men of high character and influence residing in those vicinities where local societies arose, added to the authority and consequence with which the Bible Society began to be invested, and, with other circumstances, tended greatly to enlarge its resources and increase the magnitude of its operations. The formation of juvenile and female Bible societies contributed to multiply the efforts of the Society for the circulation of the Scriptures. By means of these subdivisions, which were subordinate to their own local institution, a wider sphere of action and personal influence was created, the benefit of which extended throughout the whole system. The scholars of Holborn Sunday-school, who contributed 1*l.* 17*s.* at the eighth anniversary of the parent society in 1812, offered the first example of the young appearing as contributors to the society. The York Juvenile Bible Society, the first institution of the kind, was formed during this year, which was further distinguished by the establishment of the first Ladies' Auxiliary Society. It is right, however, to mention, that at New York, U.S., in 1809, there had been formed the Young Men's Bible Society; and at Sheffield, in 1805, when the existence of the British and Foreign Bible Society was unknown to the parties, a female association existed, whose object was the circulation of the Scriptures.

The projectors of the Bible Society not having foreseen the origin and progress of the auxiliary institutions, had made no provision for their uniform regulation; but their number had become so considerable in 1812 that the subject was forced upon them, and in the spring of that year an address was prepared, entitled, 'Hints on the Constitution and Objects of Auxiliary Societies,' the object of which was to effect the consolidation of the auxiliary societies on a just and uniform basis. In 1812 the objects and interests of the Bible Society were ably promoted by the circulation of the following tracts: 1. 'On the Advantages of Distributing the Holy Scriptures among the Lower Orders of Society, chiefly by their own agency,' by Mr. Dealtry. 2. 'An Appeal to Mechanics, Labourers, and others, respecting Bible Associations,' by Mr. Montgomery, of Sheffield. 3. 'On the Influence of Bible Societies on the Temporal Interests of the Poor,' by Mr. (afterwards Dr.) Chalmers.

The expenditure of the Bible Society, from the commencement of the Institution up to the 31st of March, 1858, has been 4,646,267*l.* 5*s.* 2*d.*, and they have issued from London 11,681,886 Bibles, or portions of the Old Testament, and 12,849,108 New Testaments, or portions of the same. On various parts of the Continent, by means of the branches of the Society and the employment of colporteurs, they have distributed 1,877,468 Bibles and parts of the Old Testament, and 7,575,484 New Testaments, or parts of it; a total of 33,983,346. The income of the Society for the year ending March, 1858, was 152,574*l.*; of which 79,041*l.* was derived from subscriptions, donations, legacies, interest on funded property, &c.; 70,267*l.* from receipts for Bibles, Testaments, and draw-backs of duty; and 2766*l.* from special contributions to a Chinese New Testament and India Fund. The total expenditure for the year was 153,177*l.*, and the society was under engagements to the amount of 83,818*l.* The abstract of the report for the year ending March 31, 1859, shows the total receipts to have been 154,906*l.*, of which 76,859*l.* had arisen from the sale of Bibles, Testaments, &c. The expenditure during the year had been 158,642*l.*, and the number of volumes issued was 1,625,985, a large increase on previous years on all the items.

These immense resources were derived, in a great measure, from the exertions of the affiliated societies. In 1858, the total number of auxiliary societies was 629; of branches, 743; and of associations, about 1800. Of these, according to the Fifty-fourth Annual Report, there were 524 auxiliary societies in England and Wales, and 402 branches. In Scotland, 27 auxiliaries and 4 branches; in Ireland, two auxiliary societies only. In the British colonies and dependencies, there were 17 auxiliary societies in North America, and 263 branches; in the West Indies, 25 auxiliaries and 3 branches; in Asia, 7 auxili-

* Auxiliary societies are allowed to purchase Bibles and Testaments at prime cost; their members have the same privileges also, at the local depositories, as the members of the parent society enjoy in London.

aries and 13 branches; in Australia, 13 auxiliaries and 39 branches; and in Africa, 9 auxiliaries and 19 branches. In Europe, there were auxiliary societies in Florence, Lucca, Hamburg, Constantinople, and Gibraltar.

The society have adopted a system of colportage (a kind of licensed hawker) in many parts of the Continent. In 1857-8 they forwarded 17,300 Bibles and 57,900 Testaments to France, of which 17,200 copies had been distributed in this way. The books are sold at a loss, and the expense of the hawking has been more than 3000*l*; but they consider the effects produced as very encouraging. In Belgium, 8000 copies of the Scriptures, either wholly or in parts, were distributed. In Holland, 22,233 Bibles were distributed, of which 2590 copies were given to schools, and two editions of the Bible in Dutch have been specially printed for them. In Germany, from the Society's three great centres, Berlin, Cologne, and Frankfort, 296,607 copies of the Scriptures were issued; making a total, since 1847, of 858,926 copies, either complete or in portions. In Denmark, 5774 copies were issued, and two large editions had been printed in Danish. In Sweden, 86,518 copies of the Scriptures, in Swedish or Finnish, were distributed; and in Norway, 18,957. In Russia, 12,290 copies of the Scriptures were distributed, chiefly through the Petersburg agency; and 10,000 Finnish Testaments and 10,000 copies of the Psalms were printed. In Switzerland and Northern Italy, 35,269 volumes had been distributed; in Sardinia, 13,647, in a great measure by colportage. In Malta and Greece, 8398 volumes had been put in circulation. In Turkey, in various languages, 10,836 copies of the Scriptures were distributed. In Spain nothing had been done, but an edition of the New Testament in Spanish had been completed, and some copies had no doubt got in from Gibraltar.

For India, Ceylon, Singapore, and China, either the whole or portions of the Holy Scriptures had been printed in the various dialects for the use of the inhabitants. At Shanghai, 50,000 Chinese Mandarin colloquial New Testaments had been printed during the year.

In all these places (except Spain) the efforts of the British Bible Society have been effectually aided by similar native institutions in Europe, and by the United States' societies in China and Australasia.

The number of auxiliary societies in connexion with the American National Bible Society is 863. The Philadelphia Bible Society, the oldest institution in the United States, has also its various branches.

On the continent of Europe the Society has printed, or extensively aided in printing, versions of the Scriptures into the French, Basque, Breton, Flemish, Spanish, Catalanian, Portuguese, Jewish-Spanish, Hebrew, Italian, Romanese, German, Bohemian, Servian, Wendish, Hungarian, Polish, Lithuanian, Danish, Swedish, Finnish, Lappone, Icelandic, Samogitian, Esthonian, Lettish, Slavonian, Wallachian, Albanian, Russian, Turkish, Turco-Greek, Tartar Turkish, Modern Greek, Calmuc, Buriat Mongolian, Manuchod, Modern Armenian, Carshun, Syriac, Georgian, Turco-Armenian, and Armenian languages. In Asia it has promoted the translation and publication of the Holy Scriptures in Persian, Arabic, Singalese, Pali, Hindostanee, Bengalee, Sanscrit, Teloo-goo, Tamul, Malay, Mahratta, Malayalim, Orissa, Seik, Birman, Carnarese, and several other dialects, together with two versions of the whole Scriptures in the Chinese, a language understood by perhaps one-fifth of the population of the globe. At Madagascar the New Testament and Psalter have been printed in Malagasse. In New Zealand the Bible has been rendered into the Maori tongue. The inhabitants of the Society and Georgian Islands have also received versions in the Tahitian languages, as well as other of the island groups in the Pacific. In Africa the ancient Church of Abyssinia has been supplied with an edition of the Ethiopic Psalter and the Gospels; and the Pentateuch, Psalter, and New Testament have been printed in the vulgar dialect of Abyssinia. Egypt has been furnished with the Psalter and the four Gospels in Coptic and Arabic. The inhabitants of a portion of Western Africa have received a part of the Scriptures in the Bullom dialect; the aborigines of Northern Africa, a translation of the Gospels and the book of Genesis in the Berber; some of the tribes of Southern Africa, the Gospels in the Namacqua dialect, besides versions in the Caffre and Sechuana. At Labrador the New Testament and Psalms have been translated into the Esquimaux language, and the New Testament and the book of Genesis into the language of Greenland.

By the Serampore missionaries.—Bhojpooree, Budrinathee, Bulochee, Bundelkhundee, Huriyana, Joypore, Munipoora Koonkee, Tripoora Koonkee, Kousoulee, Kucharee, Kutch, Mithilee, Oodoypoore, Sindhoo, and Southern Sindhoo.

The Society for Promoting Christian Knowledge, though its exertions are not confined to the issue of Bibles and Testaments, but range over a wide field, is only second to the British and Foreign Bible Society in the amount of the distribution of the Holy Scriptures. The annual diffusion of these averages over 200,000. In 1857-8, the society issued 146,270 Bibles, 69,166 New Testaments, and 300,155 Common Prayer Books, besides other books and tracts amounting to 3,700,000. The society, also, at a special general meeting, held February 10, 1834, appointed a separate committee for the purpose of superintending the publication, and more effectually promoting the circulation of the Scriptures in foreign languages. In the report for 1858, it is stated that "the committee have issued translations of the Bible in French, Italian, Dutch, German, Spanish, and Arabic. The New Testament has been published in Maltese, Polish, and Ojibwa.

The Psalter in Arabic, and triglot Psalters in French, English, and German, and in Italian, English, and Spanish, have been for some time in circulation; and a Greek Psalter, from the Septuagint, has been recently added to the catalogue. The Gospel according to St. Matthew, in the language of New Zealand; and the Gospels and part of the Acts together with a portion of the Book of Genesis, in the language of the Arawack Indians have been published. A translation of the Acts of the Apostles, in the language of the Zulu Kafirs, has been printed at the request of the Bishop of Natal. The New Testament in Coptic and Arabic has been published. The Prayer Book has been produced in French, Dutch, German, Danish, Italian, Spanish, Portuguese, modern Greek, modern Armenian, Maltese, Arabic, Turkish, Amharic, New Zealand, Ojibwa, Muncey, and Cree (North American Indian); and the orders for Morning and Evening Prayer, in the Soosoo language, have just been issued for the immediate use of the newly-established mission on the river Pongas in Western Africa." The expenditure of the society for the year, except for the working expenses of the establishment, was nearly altogether on the production of Bibles and other books, and it amounted to 80,748*l*. The receipts from sale of books was 59,520*l*., and the deficiency is amply made up by subscriptions and the interest of the accumulations. Like the Bible Society it employs foreign and colonial agencies to promote the diffusion of the Scriptures, and it has recently formed a special fund for India.

(Owen's *History of the Bible Society; Reports of the British and Foreign Bible Society; Reports of the Society for Promoting Christian Knowledge.*)

BIBLIOGRAPHY. The term *βιβλιογραφία* was used by the Greeks to signify only the writing or transcription of books; and a bibliographer (*βιβλιογράφος*) with them was a writer of books, in the sense of a copyist. The French term *Bibliographie* was long used to signify only an acquaintance with ancient writings and with the art of deciphering them. It is so explained, for instance, in the edition of Richelet's 'Dictionary,' published in 1732. The term *bibliographe* (bibliographer) is not in Richelet. It is given, however, in the 'Encyclopédie' (Paris, 1751); but both it and *bibliographie* are still explained only in the sense that has been just noticed. In the 'Dictionnaire de Trévoux,' published in 1752, we find it stated that a bibliographer is a decipherer of ancient manuscripts, with the addition, that now-a-days the name is given specially to those who are skilled in the knowledge of books and their editions, and who make catalogues of them. Accordingly, in 1763, De Bure published the first volume of his well-known work on the knowledge of rare and singular books, under the title of 'Bibliographie Instructive.' In his preface he employs the term as if the acceptance which it bears in his title-page had become familiar. In subsequent editions of the 'Encyclopédie' (for instance in the fifth volume of the Lausanne edition, printed in 1778) a new article appears on the term *bibliographie*, which consists merely of a notice of this book of De Bure's. We doubt whether the English term *bibliography*, which we have borrowed from the French, has ever had any other than this signification since its first appearance in the language.

Bibliography may be defined to be the science of books, regarded simply as such. Thus limited, it excludes all consideration either of the literary merits of a work, or of the importance or interest of the subjects which the author treats of, or of the truth or value of his statements, opinions, or speculations. It comprehends the facts—of the subject and class of the work, of its authorship and subsequent history, of the number of editions it has passed through, of the printer and publisher of each, and of its date in respect both of time and place, of the form or size (that is, the manner in which the sheets are folded, and also the size of the sheet, for the old folios are often small, such as some old editions of Bale), the quality of the paper, the number of pages, the typographical character, the number and description of the plates, the comparative completeness, correctness, and rarity, and all other external peculiarities or distinctions, of each edition. It is common to include many other things as parts of bibliography, such as a knowledge of the history, and even of the processes of the arts of printing and book-binding, as well as of the written characters of different ages. But to give such an extension to the science is to leave it without any limits whatever. If the knowledge of the art of deciphering written characters, for instance, is to be held to be a part of bibliography, then the bibliographer must be a universal linguist, in so far at least as respects the alphabets of all languages. If bibliography, again, is to include a knowledge of the arts of printing and bookbinding, why not also of those of the making of paper, parchment, papyrus, and all other substances that have ever been used for printing or writing upon, and of the composition and manufacture of inks and all other pigments? In this way bibliography would include no inconsiderable portion both of chemistry and botany. On the same principle the bibliographer might be required to have a knowledge of everything appertaining to the arts of cutting letters in wood and stone.

Although bibliography, in the sense to which it is now confined, is a very modern term, the science of the knowledge of books in regard to their authors, subjects, editions, and history, must have been cultivated from a comparatively early period in the history of literature. Indeed an acquaintance with such matters is to a great degree implied in a general knowledge of literature, such as must have been possessed by

many persons in every age of civilisation and learning. But the study must have been more systematically pursued, even in the ancient world, by those whose business it was to arrange and take charge of large libraries, of which we know that many, both public and private, existed in Greece, in Egypt, at least under the Ptolemies, in Italy, and in other countries. The principal booksellers of those days must also have been more or less conversant with what we now call the science of bibliography. We believe, however, that no professed treatise upon the subject, or upon any part of it, has either come down to us from antiquity, or is anywhere mentioned among the now lost productions either of Greek or Roman learning.

It is only since the invention of printing, and the consequent extraordinary multiplication of books, that bibliography has, properly speaking, assumed the form of a science, and been developed in its principles and details in systematic works.

In Germany, in Italy, in France, and also in our own country, works in all the departments of bibliography have, within the last three centuries, been produced in such numbers that the mere enumeration of their titles would make a bulky volume. We can here notice only a very few of the most important, and that chiefly for the purpose of illustrating the different branches into which the subject may be divided.

The most numerous class of bibliographical works are lists or catalogues of books; but these are of various descriptions. Even booksellers' catalogues are to be included under this head; such catalogues are collected and prized by bibliographers, as in many cases affording evidence both of the prices of books and of the existence of particular editions and copies. Some of them, from the superior rarity of the articles which they include, or from bibliographical notices with which they are interspersed, have a much higher value. The '*Bibliotheca Anglo-Poetica*,' for instance, published in 1815 by Messrs. Longman and Co., is perhaps the fullest list that exists of the earlier and rarer productions of English poetry, of many of which it also contains interesting bibliographical descriptions. Under the same head may be mentioned such publications as Reed's '*Bibliotheca Nova Legum Angliæ*' (1809), and other catalogues of law-booksellers, in which legal works are classified according to their subjects. Among the most valuable sale catalogues, however, are some of those of the libraries of individual collectors; such, for example, as that of the late Mr. Roscoe (prepared by himself) and published in 1816, those of the libraries of Dr. Parr (1827), of Mr. Heber (1834), of the Rev. H. F. Lyte in 1849, but which contains little more than a literal reprint of the titles arranged alphabetically according to the author's names; and above all, that of M. Libri (1859), which contains a large amount of valuable information. Among the older English catalogues of the libraries of private individuals, one of the scarcest is that of the large library of Mr. Thomas Rawlinson, which was dispersed by auction in 1722. This catalogue was published in parts, and is rarely to be found complete. Rawlinson is the person satirised under the name of Tom Folio, in the 158th number of the '*Tatler*.' Some of the most celebrated of the foreign catalogues of this description are those of the libraries of M. Cisternay du Fay (8vo, 1725), of the Comte de Hoym (8vo, 1728), of the Abbé Charles d'Orléans de Rothelin (8vo, 1746), and of M. Claude Gros de Boze (8vo, 1753), all prepared by the Parisian bookseller, Gabriel Martin. There is another catalogue of the library of M. de Boze, printed under his own care at the royal press in small folio in 1745, which is of extreme rarity, only fifty copies, it is said, having been thrown off. De Bure states that a single copy has been sold for nearly 240 livres. In all these catalogues of Martin's the books are arranged in classes according to a scheme of his own contrivance, and an alphabetical catalogue of the names of the authors is given at the end. Perhaps, however, the most comprehensive and valuable catalogue thus digested that has ever been published is that entitled the '*Bibliotheca Bunaviana*,' 7 vols. 4to, Leipzig, 1748-1756, being a catalogue of the library of the Count de Bunau, drawn up by his librarian, Jo. Mich. Franck. The divisions and subdivisions in this catalogue are much more numerous than those in Martin's system. The work has the highest character for accuracy, so far as it goes: but unfortunately it never was completed.

Some '*Catalogues Raisonnés*' (as catalogues in which the books are thus disposed into classes according to their subjects are called by the French) have also been printed of public libraries. The greatest work of this description is probably that of the French '*Bibliothèque Royale*,' begun in 1739, and finished in ten volumes folio in 1753. This catalogue consists of two parts, one of the printed books, and another of the manuscripts. The former was originally superintended by the Abbés Sallier and Boudot, the other by Anicet Mellot. The most complete catalogue of this description in existence is understood to be that of the library of the university of Gottingen, but it has not been printed. (See an account of this Catalogue in the '*Quarterly Journal of Education*,' No. IV.) The best specimen of a '*Catalogue Raisonné*' that we know of any of the more considerable public collections of this country, is that of the library of the Writers to the Signet in Edinburgh, published in one volume quarto in 1805. The catalogues of the libraries of some mechanics' institutes and other private associations have more recently been published upon a similar plan. That of the London Institution in Finsbury Circus, is an excellent specimen; the works are classified and described in the body, and there are two indexes, one of subjects,

and one of authors and books, arranged alphabetically. It is to be observed that a '*Catalogue Raisonné*' implies something more than a distribution of the books into so many distinct alphabets, severally headed Theology, History, Voyages and Travels, Novels and Romances, Poetry, Medicine, Law, &c., as we find done even in many catalogues of circulating libraries, and booksellers' and auctioneers' sale catalogues. In a '*Catalogue Raisonné*,' properly so called, the alphabetical arrangement of titles is entirely dispensed with, its place being supplied by an index at the end; and every work is set down in the order pointed out by its subject, the ground over which the author's researches or speculations extend being at the same time indicated as distinctly and fully as possible, not only by the transcription of the title-page, but, when necessary, by an abstract of the contents. This is especially done in the case of publications that consist of collections of treatises.

There are printed catalogues of most of the public collections of books in this country; but, with the exceptions just mentioned, they are all, we believe, merely alphabets of titles, and even as such few of them have been very carefully drawn up. One of the most inaccurate and deficient is the old catalogue of the printed books in the general library of the British Museum, which was published in 1813-1819, in seven octavo volumes. That of the Royal Library, in the same depository (five volumes folio, besides a catalogue of maps, prints, &c., in one volume, 1820-1829), was prepared with much greater care. The great manuscript catalogue in the Reading-room of the British Museum will, when completed, be probably the finest catalogue in Europe. There are also excellent printed catalogues of the Harleian, Cottonian, Lansdowne, Sloane, and Birch manuscripts, all preserved in this extensive national collection.

A higher description of catalogues are those not of particular collections, but of books generally, or of certain classes of books, arranged in reference either to their subjects, their dates, their authors, or their titles.

One of the earliest attempts made to present in this way what we may call a complete survey of printed literature was that of Conrad Gesner, in his '*Bibliotheca Universalis*,' published in one volume folio in 1565. In this catalogue the works are arranged according to the names of the authors; but although designated an universal library, it is confined to books in the Greek, Latin, and Hebrew languages, which, although comprehending by far the greater part, did not even then include the whole of literature. Gesner, however, remains to the present day without any successor in his vast enterprise. No subsequent work has appeared professing to survey in the same manner the whole field of existing literature. The nearest approach that has been made to anything of the kind is in the '*Bibliotheca Britannica*' of Dr. Robert Watt, of Glasgow, four vols. 4to, Edin. 1824. This is a most elaborate, meritorious, and useful work; but, as its title indicates, it is to be considered as aiming at completeness only in regard to English works; those which it notices in other languages, although also amounting to a very large number, being professedly only a selection. Owing also to the residence of the author in a remote provincial town, where he was precluded from access to many of the most valuable sources of information, his work is neither so full nor so correct as with better opportunities it might have been made; and some additional inaccuracies have crept into it from his not having lived to see it through the press. With all these drawbacks, however, it is still an extraordinary monument of industry, and a help to the student of very great value. It consists of two parts, in the first of which the books are arranged according to the names of the authors, and in the second alphabetically according to their titles.

In a few cases attempts have been made to present catalogues of all the works written in some single language, or by the authors of some single country. As examples of catalogues of this description may be mentioned the '*Illustrum Majoris Britanniae Scriptorum Summarium*' of John Bale, first published in 1458 (for an account of which see BALE, JOHN, in BIOG. DIV.); the '*De Academiis et Illustribus Angliæ Scriptoribus*' of John Pits, the first volume of which (the only one ever published) appeared at Paris, in 4to, in 1619; the '*Bibliotheca Britannico-Hibernica*' of Bishop Tanner, folio, 1748; the '*Bibliotheca Belgica*' of John Francis Foppens, 2 vols. 4to, 1739; and the '*Bibliotheca Hispana, Nova et Vetus*,' 4 vols. folio, 1672 and 1696, of Nicholas Antonio. Under this head also may be mentioned the several admirable works of John Albert Fabricius, entitled the '*Bibliotheca Latina*,' 2 vols. 4to; the '*Bibliotheca Mediæ et Infimæ Latinitatis*,' 6 vols. 4to; and the '*Bibliotheca Græca*,' the second edition of which, by Harles, published at Hamburg in 1790-1809, is in 12 volumes, 4to. Dr. Dibdin's '*Introduction to a Knowledge of Rare and Valuable Editions of the Greek and Roman Classics*,' first published in 1802, has been several times reprinted, but is not of any great value.

A much more numerous class of catalogues are those of all the books written either in some one language, or in all languages, upon a particular department of knowledge. Thus we have the '*Bibliotheca Theologica*,' the '*Bibliotheca Juridica*,' the '*Bibliotheca Philosophica*,' and the '*Bibliotheca Medica*,' of Martin Lipenius, or the whole collected in six volumes, folio, under the title of '*Bibliotheca Realis*.' To the '*Bibliotheca Juridica*' valuable supplements were added by Scholt in 1775, and by Seckenberg in 1789, which have increased the work to four volumes folio. One of the very best of this class of works is the great French work by the Père Le Long, entitled '*Bibliothèque Historique*

de la France,' an account of works both printed and manuscript on French history, the last edition of which, published at Paris in 1768-1778, is in five volumes folio. The 'Bibliotheca Historica' of Meusel, published at Leipzig in 1782-1804, in twenty-two volumes, 8vo, is much more extensive in its design, comprehending both historical and geographical works relating to all countries and in all languages. Other works of this class are the 'Bibliotheca Magna Rabbinica' of Julius Bartoloccius, 4 vols. fol. Rome, 1675, with the supplement of C. J. Imbonatus, fol. Rome, 1694; the 'Scriptorum Ecclesiasticorum Historia Literaria' of Cave, 2 vols. fol. Oxford, 1740; Luke Wadding's 'Scriptores Ordinis Minorum,' fol. Rome, 1650 (a highly esteemed and scarce work); Ribadeneira's 'Bibliotheca Scriptorum Societatis Jesu,' fol. Rome, 1676; Le Long's 'Bibliotheca Sacra' (an account of the editions of the Scriptures, and of the versions of them in various languages), 2 vols. fol. Par., 1723; the 'Bibliotheca Scriptorum Veterum et Recentiorum' of J. J. Manget, 4 vols. fol. Geneva, 1731; the Rev. T. H. Horne's 'Manual of Biblical Bibliography,' 1839; the 'Bibliotheca Mathematica' of Murhard, 5 vols. 8vo, Leipz. 1797-1805; the 'Bibliographie Astronomique' of La Land, 4to, Paris, 1803; the 'Bibliographical Account of the Principal Works relating to English Topography,' by Mr. Upcott, 3 vols. 8vo, 1818, one of the most accurate of this description of publications; De Morgan's 'Notices of Arithmetical Books and Authors,' 8vo, 1847; Darling's 'Cyclopædia Bibliographica, a Library Manual of Theological and General Literature, and Guide to Books,' 1857-58, a work of great value; and 'Bibliographie Biographique; ou, Dictionnaire de 26,000 Ouvrages relatifs à l'Histoire de la Vie des Hommes Célèbres,' par Edouard Marie Oettinger, Leipzig, 1850.

Another subdivision of this class of bibliographical works consists of catalogues of all such books as have been published up to a certain date posterior to the invention of printing, or of those that have appeared in some particular age, or that have issued from some particular press. Among the most remarkable of these are Maittaire's 'Annales Typographicae ab artis inventæ origine,' 5 vols. 4to, of which the first was published in 1719 at the Hague, and the last at London in 1741 (to this should be added the supplement by Denis, 2 vols. 4to, Vienna, 1789); Panzer's 'Annales Typographicae ab artis inventæ origine,' 11 vols. 4to, Nuremberg, 1793-1803, in which work, founded upon the preceding, the list of books is brought down to the year 1536; Ames's 'Typographical Antiquities, being an Historical Account of Printing in England from 1471 to 1600,' of which a new and enlarged edition was issued, in 4 vols. 4to, by the Rev. T. F. Dibdin in 1810-12; Maittaire's 'Historia Stephanorum,' 2 vols. 8vo, London, 1709; Maittaire's 'Historia Typographorum Aliquot Parisienium,' 2 vols. 8vo, London, 1717; and Renouard's 'Annales de l'Imprimerie des Alde,' 2 vols. 8vo, Paris, 1803.

To these works are to be added many others, which proceed upon a principle of selection. Such are the following: A. Beyer's 'Memoriae Historico-criticæ Librorum Rariorum,' 8vo, Dresd. et Leipz. 1734; J. Vogt's 'Catalogus Historico-Criticus Librorum Rariorum,' 8vo, Hamb. 1753, and again, improved, in 1793; S. Engel's 'Bibliotheca Selectissima, seu Catalogus Librorum in omni genere scientiarum rarissimorum, cum notis bibliographicis,' 8vo, Bern. 1743; D. Clement's 'Bibliothèque Curieuse, ou Catalogue Raisonné des Livres rares et difficiles à trouver,' 9 vols. 4to, Göttingen, 1750-60. This extensive work, in which the titles of the books are arranged alphabetically, comes down only to the letter H, having been stopped at that point by the death of the author. De Bure's 'Bibliographie Instructive, ou Traité de la Connoissance des Livres rares et singuliers, contenant un Catalogue Raisonné de la plus grande partie de ces livres précieux qui ont paru successivement dans la République des Lettres, depuis l'Invention de l'Imprimerie,' 7 vols. 8vo, Paris, 1763-68. In 1769 the author published a catalogue of the library of Louis Jean Gaignat, in 2 vols. 8vo, under the title of a supplement to his 'Bibliographie;' and in 1782 a tenth volume was added to the work, being an index to the anonymous books mentioned in it, which were not included in the original index. Of the original seven volumes, the first is occupied with theology, the second with jurisprudence and the sciences and arts, the third and fourth with the belles lettres, the fifth and sixth with history, and the last with a general index to the whole, in which the books are classed according to the names of the authors. Probably no publication has contributed so much to make the study of bibliography popular as this elegant and judicious performance. Even at the present day it may be recommended as the most attractive manual of bibliographical knowledge that has yet been produced. Notwithstanding considerable deficiencies, and also some inaccuracies, the student will collect from it, more readily than from any other source, a knowledge of the titles and best editions of most, not only of the rarest but also of the most important works that had issued from the press up to the time of its appearance. It is astonishing what an extent of ground the author contrives to go over in his limited space. The articles which he describes amount to above 6000 in number; and, in regard to many of them, very ample details are given. Osmont's 'Dictionnaire Typographique, Historique, et Critique, des Livres rares, estimés, et recherchés en tous genres,' 2 vols. 8vo, Paris, 1768; J. J. Bawer's 'Bibliotheca Librorum Rariorum Universalis,' 7 vols. 8vo, 1770-91; F. X. Laire's 'Index Librorum ab Inventâ Typographia ad annum 1500, cum notis,' 2 vols. 8vo, 1791; Dr. Adam Clarke's 'Bibliographical

Dictionary of the most curious and useful books, in Latin, Greek, Hebrew, Arabic, and other Eastern languages,' 6 vols. 12mo, 1803, with a Supplement, containing an account of English translations of the classics and theological writers, published under the title of the 'Bibliographical Miscellany,' in 2 vols. 12mo, in 1806; S. Santander's 'Dictionnaire Bibliographique choisi du Quinzième Siècle,' 3 vols. 8vo, 1805; Brunet's 'Manuel du Libraire, et de l'Amateur des Livres,' 2nd edit., 4 vols. 8vo, 1814, a very useful work, of which a new and enlarged edition is said (1859) to be in course of preparation by the author; Dibdin's 'Library Companion,' 2 vols. 8vo, London, 1824; Goodhugh's 'English Gentleman's Library Manual,' 8vo, 1827; Lowndes's 'Bibliographer's Manual of English Literature,' 4 vols. 8vo, London, 1834, of which a new and enlarged edition was published in 1858; Ventouillac's 'French Librarian,' 8vo, 1829; the 'Bibliotheca Historica Selecta' of B. B. G. Struvius, 8vo, 1705, and greatly augmented by C. G. Buder, 2 vols. 8vo, 1740; the catalogue of the principal historical writers appended to the Abbé Lenglet du Fresnoy's 'Méthode pour étudier l'Histoire,' 6 vols. 4to, Paris, 1729-40, or that forming the second volume of the English translation of part of the same work, by Dr. Richard Rawlinson, 2 vols. 8vo, London, 1730; Archbishop Nicolson's 'Historical Libraries of England, Scotland, and Ireland,' 4to, 1776; the 'Lettres sur la Profession d'Avocat, et Bibliothèque choisie des Livres de Droit,' of M. Camus; the catalogue of works relating to natural philosophy and the mechanical arts, annexed to the late Dr. Young's 'Lectures on Natural Philosophy;' the late Dr. Mason Good's 'Study of Medicine,' 5 vols. 8vo, 1829; A. Baillet's 'Jugemens des Savans sur les Principaux Ouvrages des Auteurs,' augmenté par M. de la Monnoye, 8 vols. 4to, Amsterdam, 1724; the 'Censura Literaria,' of Sir Egerton Brydges, 10 vols. 8vo, 1805-09; Hartshorne's 'Book Rarities in the University of Cambridge,' 8vo, London, 1829. Under this head also may be noticed the learned and admirable work of D. G. Morhof, entitled 'Polyhistor Literarius, Philosophicus, et Practicus,' first published in 1688, but the best edition of which is that of J. A. Fabricius, in 2 vols. 4to, 1747; the very erudite and elaborate 'Onomasticon Literarium' of C. G. Sax, or Saxius, published at Utrecht, in 7 vols. 8vo, from 1759 to 1790, with a supplementary volume which appeared in 1803; and 'Trésor des Livres rares et précieux,' on the same plan as that of Brunet, but containing a vast addition of information regarding works in the languages of northern and eastern Europe, Russian, Polish, Greek, &c., compiled by J. T. Grasse, of Dresden, which is being issued in parts, only four having been yet (May, 1859) published. 'The Critical Dictionary of English Literature, and British and American Authors living and deceased,' published also in 1859, is only partly bibliographical, as its 30,000 notices of authors and their works, are critical and biographical; it has forty indexes of subjects which are bibliographically useful, but it has no pretence to completeness.

There is one class of books, which, from a peculiarity by which they are distinguished, has frequently been treated by itself in bibliographical works; we mean the class of books which have not the names of their authors on the title-page. In 1690, Adrien Baillet published, not a very profound, but still a curious treatise upon books of this description, under the title of 'Auteurs Déguisez sous des noms étrangers, empruntés, supposés, feints à plaisir, abrégés, chiffrés, renversés, retournés ou changés d'une langage en une autre;' which was afterwards incorporated in the fifth volume of La Monnoye's edition of the 'Jugemens des Savans,' along with many annotations and corrections. At the end of this dissertation, which is divided into four parts, is given a list of false names assumed by authors, with their interpretation, as far as known, which extends to between sixty and seventy columns. A few years before the publication of Baillet's work, namely, in 1674, Vincent Placcius had printed a small tract in 4to. at Hamburg, entitled 'De Scriptis et Scriptoribus Anonymis atque Pseudonymis Syntagma.' In 1708 this work re-appeared under the superintendence of the indefatigable Jo. Alb. Fabricius, and of Mat. Dreyer, a lawyer of Hamburg, enlarged to 2 vols. fol. by the insertion of much new matter, and also by the addition of the following tracts upon the same subject, which had been previously printed:—'De Nominum Mutatione,' by F. Geisler, 1669, and again in 1671; 'Conjecturæ de Scriptis Adespotis, Pseudepigraphis, et Supposititiis,' by John Decker, 1678 and 1686; and 'Dissertatio Epistolica ad Placcium, qua Anonymorum et Pseudonymorum farrago exhibitur,' by Jo. Mayer, 1689. To the whole was now given the title of 'Vincentii Placcii Theatrum Anonymorum et Pseudonymorum.' To this should be added the Supplement published in 1 vol. folio, and also in 2 vols. 8vo, at Hamburg, in 1740, by Jo. Ch. Mylius, in which is comprised a reprint of the preceding Supplement, published at Jena in 1711, by Ch. Aug. Neuman, under the title of 'De Libris Anonymis et Pseudonymis Schediasma, complectens observationes generales, et Spicilegium ad Placcii Theatrum.' The original work, and the supplement of Mylius, together comprehend between nine and ten thousand articles.

But of all the works in this department of bibliography, by far the most perfect and valuable is the 'Dictionnaire des Anonymes et Pseudonymes' of the late M. Barbier, administrator of the private libraries, first of the Emperor Napoleon, and afterwards of Charles X. of France. The first two volumes of the first edition of this admirable work appeared in 1806, and were followed by two more in 1809. The publication of a second and greatly improved and enlarged edition was

commenced by the author in 1822, and completed by him in 3 vols. in 1824, about a year before his death. A supplementary volume, which he left ready for the press, has since been published by his son. The Dictionary of Barbier is confined to works in the French and Latin languages, but of these it notices between twenty-three and twenty-four thousand.

Of a somewhat different class is that of the works and editions of a particular author. Of this class, a favourable specimen is the 'Alphabetical Catalogue of an extensive Collection of the writings of Daniel De Foe, and of the different publications for and against that remarkable writer,' published in 1830, which was compiled by Thomas Rodd. Of private collections the 'Bibliotheca Spenceriana,' an account of the library at Althorp, by Dr. Dibdin, is perhaps unequalled in the style of its getting up, and contains much curious and interesting matter connected with that large and valuable library.

For further information upon the different branches of bibliography the reader may refer to the Rev. T. H. Horne's 'Introduction to the Study of Bibliography,' 2 vols. 8vo, Lond. 1814; C. F. Achard's 'Cours de Bibliographie,' 3 vols. 8vo, Marseilles, 1807; 'Handbuch der Deutschen Literatur, seit der mitte des achtzehnten Jahrhundert bis auf die neueste Zeit systematische bearbeitet, und mit den nöthigen Registern versehen: Neue, mit verschiedenen Mitarbeitern besorgte Ausgabe,' 4 vols. 8vo, Leipzig, 1822-27. See also J. M. Quérard, 'La France Littéraire: ou Dictionnaire Bibliographique des savants, historiens, et gens-de-lettres, de la France; ainsi que des littérateurs étrangers qui ont écrit en Français, plus particulièrement pendant les 18ième et 19ème siècles,' 10 vols. 8vo, Paris, 1827-42: O. Rich, 'Bibliotheca Americana Nova: or a Catalogue of Books in various languages relating to America, printed since the year 1700; compiled principally from the books themselves,' 8vo, Lond. 1835. Among works of this class might also be mentioned such as P. J. Safarik's 'Geschichte der slawischen Sprache und Literatur nach allen Mundarten,' Buda, 1826, which is a great storehouse of information on Slavonic literature, rather of a bibliographical than historical character; its principal feature being its very full lists of titles of books.

BIBROMANILINE, *Dibromaniline*. [ANILINE.]

BIBROMANTHIC ACID. [EUXANTHIC ACID.]

BIBROMISATIC ACID. [INDIGO.]

BIBROMOQUINONIC ACID. [QUINONIC ACID.]

BIBROMOSALICYLIC ACID. [SALICYLIC ACID.]

BICHLORHYDRIN. [GLYCERIN.]

BICHLOROXALIC ACID ($C_8Cl_4O_6 \cdot 2HO$). This acid, which has never been obtained in a separate state, is one of the products of the action of chlorine upon citric acid. The potash and silver salts only have been examined.

BIDPAI, Pancha Tantra, or Fables of. [PILPAY, in BIOG. DIV.]

BIELA'S COMET. [COMETARY BODIES.]

BIENNIALS are plants which require two seasons of growth to produce their flowers and fruit; they differ from annuals in nothing but this circumstance, perishing as soon as their seeds are ripened.

BIGA, a chariot or car drawn by two horses: called by Suetonius ('Calig.' c. 19.) *Bijuge curriculum*. The biga was the most common chariot in use among the Romans. They had also their trigæ, quadrigæ, and sometimes their sejuges septim-juges, &c., and Suetonius assures us that Nero, when he was a performer in the Olympic games, made use of a decem-jugis, a chariot drawn by ten horses coupled together. (Suet. in Ner. c. 24.)

Pliny attributes the invention of the biga to the Phrygians. ('Hist. Nat.' lib. vii. c. 56.) Isidorus says the inventor was Cristines the Sicyonian. ('Origines,' lib. xvii. c. 35.)

The Roman silver coins stamped with a form of a chariot drawn by two or four horses were called *bigati*, and *quadrigati*. (See Pliny, ARTS AND SCI. DIV. VOL. II.

'Hist. Nat.' lib. xxi. c. 3.) Hence Livy (lib. xxxiii. c. 23.) uses the term *argentum bigatum*. The bigati, quadrigati, and victoriati, were all of equal value, and differed only in the impress from which they derived their several names. The biga was an emblem of victory.

BIGAMY, in the canon law, signified either a second marriage after the death of the first wife, or a marriage with a widow. It incapacitated men for holy orders; and until the stat. 1 Edw. VI. c. 12, s. 16, it was a good counterplea to the claim of benefit of clergy. (Wooddesson's 'Vinerian Lectures,' i. 425.)

Bigamy, by the English law, consists in contracting a second marriage during the life of a former husband or wife, and the statute 1 James I. c. 11. enacts that the person so offending shall suffer death, as in cases of felony. This statute has been repealed by 9 Geo. IV. c. 31, s. 22, which makes any person who being married shall marry any other person during the life of the former husband or wife, whether the second marriage shall have taken place in England or elsewhere, and any person aiding, guilty of felony, and punishable by transportation for seven years (for which penal servitude has since been substituted), or imprisonment (with or without hard labour) for a term not exceeding two years. The statute excepts, first, any second marriage contracted out of England by any other than a subject of his Majesty; second, any person whose husband or wife shall have been continually absent during seven years, and shall not have been known by such person to have been living within that time; third, a person divorced from the bond of the first marriage; fourth, one whose former marriage shall have been declared void by the sentence of a court of competent jurisdiction.

With respect to the *third* exception it has been determined in a case where a Scotch divorce *a vinculo* was pleaded, that no sentence of any foreign court can dissolve an English marriage *a vinculo* unless for grounds on which it was liable to be so dissolved in England; and that the term "divorced" applies to the sentence of a spiritual court within the limits to which the statute extends. The *fourth* exception cannot be taken advantage of, if the first marriage has been declared void only collaterally and not directly; or if it can be shown to have been obtained fraudulently or collusively.

BILIFULVIN. A yellow colouring matter found by Berzelius in the bile. Its composition is unknown, but it appears to be the lime or soda salt of a peculiar acid.

BILIN. [CHOLIC ACID.]

BILIPHEIN ($C_{32}H_{18}N_2O_9$?). A brown colouring matter found in the bile, and in the intestinal canal. It is to this substance that the solid excrements owe their colour. As an abnormal constituent, it is also met with in the blood; and the yellow tint of the skin and of the cornea in jaundice is likewise due to this substance. Biliary calculi are often almost entirely composed of this body, and constitute the best source of biliphein, which may be prepared pure by washing the powdered calculi successively with ether, alcohol, boiling water, hydrochloric acid, and cold water; finally dissolving the residue in a weak solution of carbonate of soda, and then re-precipitating with an acid. Whilst the biliphein is in solution, it is necessary to preserve it carefully from the air, otherwise it oxidises and is converted into *biliverdin*. The solution must therefore be operated upon in an atmosphere of hydrogen gas.

Biliphein is a brown, amorphous, infusible solid, insoluble in boiling water, but soluble in boiling alcohol. The alcoholic solution gradually absorbs oxygen from the air, and becomes green. It dissolves slightly in hydrochloric acid, with a blue colour. If red nitric acid be added in excess to a dilute alkaline solution of biliphein, the liquid becomes at first green, and subsequently passes through various shades of blue, violet, and red, until it finally becomes yellow.

BILIVERDIN ($C_{16}H_6NO_5$?). A green colouring matter found in ox-gall, and also produced by the oxidation of biliphein. It is insoluble in water, but dissolves in alcohol with a green colour. [BILIPHEIN.]

BILL CHAMBER, a department of the Court of Session in Scotland, in which one of the judges officiates at all times during session and vacation. The youngest judge is lord ordinary on the bills during session; the duty is performed by the other judges, with the exception of the two presidents, by weekly rotation during vacation. All proceedings for summary remedies, or for protection against impending proceedings, commence in the Bill Chamber—such as interdicts (or injunctions against threatened injuries, or against courts exceeding their jurisdiction, as in the case of the church courts attempting to take cognisance of civil questions), or suspension of execution. The process of sequestration [BANKRUPT LAWS OF SCOTLAND] issues from this department of the court. By far the greater number of the proceedings are sanctioned by the judge as a matter of form, on the clerks finding that the papers presented ask the usual powers in the usual manner; but where a question of law is involved in the application, it comes into the Court of Session, and is discussed as an ordinary action. The Lord Ordinary on the Bills, as he is termed, is the representative of the court during vacation.

BILL IN CHANCERY. [EQUITY.]

BILL IN EQUITY. [PLEADING IN EQUITY.]

BILL IN PARLIAMENT, is the name given to any proposition introduced into either house for the purpose of being passed into a law, after which it is called an act of parliament, or statute of the realm. [STATUTE.]

In modern times a bill does not differ in form from an act, except that when first brought in, it often presents blanks for dates, sums of money, &c., which are filled up in its passage through the house. When printed, also, which (with the exception only of naturalisation and name-bills, which are not printed) it is always ordered to be, either immediately after it has been read a first time, or at some other early stage of its progress, a portion of it, which may admit of being disjoined from the rest, is sometimes distinguished by a different type. But most bills are several times printed in their passage through the two houses. A bill, like an act, has its title and its preamble, usually setting forth the reasons upon which it professes to be founded, and concluding "Be it therefore enacted by the Queen's most excellent Majesty, by and with the advice and consent of the Lords Spiritual and Temporal, and Commons, in this present Parliament assembled, and by the authority of the same as follows;" after which come the enacting clauses in their order. The advantage of this is that a bill becomes a law at once on receiving the royal assent.

Originally, the bills passed by the two houses were introduced in the form of petitions, and retained that form when they came to receive the royal assent. The whole of those passed in one session were then, after the parliament rose, submitted to the judges, to be by them put into the proper shape of a law. But it was found that in undergoing this process the acts, as passed by the parliament, were frequently both added to and mutilated. Indeed a great deal of the power of making the law was thus left in the hands of the judges, and of the royal authority, in so far as these learned personages might be under its influence. To remedy this evil it was arranged in the reign of Henry V., that the statute roll of the session should always be drawn up before the parliament rose. In the following reign, that of Henry VI., the bill came as now to be prepared in the form of an act.

Bills are either public or private. In the introduction of a public bill the first motion made in the House of Lords is that the bill be brought in; but in the House of Commons the member who purposes to introduce the bill must first move that leave be given to bring it in. If that motion is carried, the bill is then either ordered to be brought in by certain members, generally not more than two, of whom the mover is one. A select committee is sometimes appointed for that purpose. When the bill is ready, which it frequently is as soon as the motion for leave to bring it in has been agreed to, it is presented at the bar by one of those members, and afterwards, upon an intimation from the speaker, brought up by him to the table. The next motion is that it be read a first time; and this motion is most frequently made immediately after the bill has been brought up. This being carried, a day is appointed for considering the question that the bill be read a second time. The second reading being carried, it is next moved that the bill be committed, that is, that it be considered clause by clause either in a committee of the whole house, or, if the matter be of less importance, in a select committee appointed for the purpose. When the committee have finished their labours they make their report through their chairman; and the next motion is that the report be received. Besides modifying the original clauses of the bill, it is in the power of the committee, if they think proper, both to omit certain clauses, and to add others. Sometimes a bill is ordered to be re-committed, that it may undergo further consideration, or that additional alterations may be made in it. The report of the committee having been received, the next motion is that the bill be read a third time, and when that is carried, there is still a further motion, that the bill do pass. When a bill has passed the House of Lords, it is sent down to the House of Commons, usually (since the abolition of the office of master of chancery,) by the clerk assistant, or reading clerk, sometimes by the Queen's Sergeant, and occasionally, in the case of measures of great importance, by one or more of the judges, who make three obeisances as they advance to the speaker, and, after one of them has read the title of the bill, deliver it to him, desiring that it may be taken into consideration. When a bill, on the other hand, is sent up from the Commons to the Lords, it is sent by several members (the speaker being frequently one), who, having knocked at the door of the Lords' house, are introduced by the usher of the black rod, and then advance to the bar, making three obeisances. The speaker of the house, who is usually the lord chancellor, then comes down to the bar, and receives the bill, the member who delivers it to him stating its title, and informing him that it is a bill which the Commons have passed, and to which they desire the concurrence of their lordships. A bill thus received by the one house from the other is almost always read at least a first time; but it does not appear to be a matter of course that it should be so read. It then goes again through the same stages as in the other house.

The bill may be debated on any one of the motions which we have mentioned, and it commonly is so debated more than once. It is usual, however, to take the debate upon the principle of the proposed measure either on the motion for leave to bring in the bill, or on that for the second reading; the details are generally discussed in the committee. Amendments upon the bill, going either to its entire rejection, or to its alteration to any extent, may be proposed on any occasion on which it is debated after it has been brought in. Before it is committed also certain instructions to the committee may be moved, upon which the committee must act.

Bills were formerly engrossed after the report of the committee, on

rolls of parchment, and in the same shape sent to the other house, and after the royal assent enrolled as statutes; clauses added being engrossed on separate sheets, and attached to the bill as *riders*. This system was discontinued in 1849, and printing substituted.

Bills of all kinds may originate in either house, except what are called money bills, that is, bills for raising money by any species of taxation, which must always be brought first into the House of Commons. The Commons also will reject any amendment made upon a money bill by the Lords. The Lords again have a standing order against proceeding with any bill for restitution in blood which shall not have originated in their own House.

When a bill has passed the Commons and is to be sent up to the Lords, the clerk writes upon it *Soit baillé aux Seigneurs*; and upon one which has passed the Lords and is to be sent down to the Commons, the clerk of the Lords writes *Soit baillé aux Communs*. If it is afterwards passed by the Commons, the clerk writes upon it *Les Communs ont assentez*. All bills of supply, after being passed by the Lords, are returned to the House of Commons, in which they had originated, and there remain till they are brought to the House of Lords by the speaker to receive the royal assent: all other bills are deposited with the Lords till the royal assent is given to them.

A bill, after it has been introduced, may be lost either by the royal assent being refused (of which, however, there is no instance in recent times), or by a motion for its rejection being carried in any of its stages in its passage through either house, or by any of the motions necessary to advance it on its progress being dropped or withdrawn. The rejection of the bill may be effected by the motion in its favour being simply negatived, or by a counter-motion being carried to the effect that the next reading be deferred till a day by which it is known that parliament will have been prorogued (generally till that day six months, or that day three months), or by the carrying of an amendment entirely opposed to the measure. The motion for carrying it forward on any of its stages may be dropped either by the House not assembling on the day for which the order made respecting that motion stands, or simply by no member appearing to make the motion. When a motion has once been made, it can only be withdrawn by consent of the House.

If a bill has been lost in any of these ways, the rule is that the same measure cannot be again brought forward the same session. "It however appears," says Mr. Hatsell, in treating of this subject in his 'Precedents,' "from several of the cases under this title, as well as from every day's practice, that this rule is not to be so strictly and verbally observed as to stop the proceedings of the house: it is rather to be kept in substance than in words; and the good sense of the House must decide, upon every question, how far it comes within the meaning of the rule." In fact there are several remarkable examples of the regulation being entirely disregarded. And sometimes a short prorogation has been made merely to allow a bill which had been defeated to be again introduced.

When a bill which has passed one house has been amended in the other, it must be returned, with the amendments, to be again considered in the house from which it had come; and it cannot be submitted for the royal assent until the amendments have been agreed to by that house. In case of a difference of opinion between the two houses, the subject is frequently ordered to be discussed in a conference. [AMENDMENT.]

According to the standing orders of the House of Commons, no bill relating to religion, or trade, can be brought into the House until the proposition shall have been first considered and agreed to in a committee of the whole house; and the house will not proceed upon any petition, motion, or bill for granting any money, or for releasing or compounding any sum of money owing to the crown, but in a committee of the whole house. No bill also can pass the house affecting the property of the crown or the royal prerogative, without the royal consent having been first signified.

Private bills are such as directly relate only to the concerns of private individuals, or bodies of individuals, and not to matters of state or to the community in general. In some cases it might be doubtful whether an act ought to be considered a public or a private one; and in these cases a clause is commonly inserted at the end of the act to remove the doubt. Private bills in passing into laws go through the same stages in both houses of parliament with public bills; but relating as they do for the most part to matters as to which the public attention is not so much alive, various additional regulations are established with regard to them, for the purpose of securing to them in their progress the observation of all whose interests they may affect. No private bill, in the first place, can be introduced into either house except upon a petition stating its object and the grounds upon which it is sought. Nor can such petitions be presented after a certain day in each session, which is always fixed at the commencement of the session, and is usually within a fortnight or three weeks thereafter. In all cases the necessary documents and plans must be laid before the house before it will proceed in the matter, and it must also have evidence that sufficient notice in every respect has been given to all parties interested in the measure. To a certain extent the consent of these parties is required before the bill can be passed. For the numerous rules, however, by which these objects are sought to be secured, we must refer to the Standing Orders themselves, which prescribe most minutely the

principal steps necessary to be taken in the case of all descriptions of private bills, which are principally for enabling associations of individuals to undertake the formation of railways, roads, canals, docks, and other such works.

An important respect in which the passage through parliament of a private bill differs from that of a public bill is the much higher amount of fees paid in the case of the former to the clerks and other officers of the two houses. Although the high amount of the fees payable on private bills has been the subject of much complaint, and is undoubtedly, in some cases, a very heavy tax, it is to be remembered that the necessary expense of carrying the generality of such bills through parliament must always be very considerable, so long as the present securities against precipitate and unfair legislation shall be insisted on. The expenses of agency, of bringing up witnesses, and the other expenses attending the making application to parliament for a private bill, at present often amount to many times as much as the fees. These fees, on the other hand, are considered to be some check upon unnecessary applications for private bills, with which it is contended that parliament would otherwise be inundated. The misfortune is, that it is not the most unnecessary applications which such a check really tends to prevent, but only the applications of parties who are poor, which may be just as proper to be attended to as those of the rich.

A useful little manual on 'Private Bill Legislation, comprising the steps required to be taken by Promoters or Opponents of a Private Bill,' has been prepared by J. B. Bristowe, Esq., Barrister-at-Law, and was published early in 1859.

BILL OF EXCHANGE, a well-known mercantile instrument, of great and extensive usefulness, which may be described as a written order or request addressed by one person to another, directing the latter to pay on account of the former to some third person or his order, or to the order of the person addressing the request, a certain sum of money at a time therein specified. In commercial language, the person giving this direction is called the drawer of the bill;—he to whom it is addressed the drawee, or, if he accepts it, the acceptor;—he in whose favour it is given the payee: if the payee indorses it, he is called an indorser, and the person to whom it is indorsed, the indorsee, who may in turn likewise become an indorser. Bills of Exchange are in this country classified as foreign or inland bills. This distinction is more than nominal, for it carries with it legal consequences of importance, and depends upon the following circumstances. If the drawer or drawee, or, if both the drawer and drawee of a bill, are resident in a foreign country, it is a foreign bill; but it is an inland bill, if it is both drawn and made payable—or if drawer and drawee are both—within the territory of the United Kingdom of Great Britain and Ireland, the islands of Man, Guernsey, Jersey, Alderney and Sark, and the islands adjacent to any of them, being part of the dominions of her Majesty. Thus, a bill drawn by a person in France upon a person in England, or conversely, by one in England upon another in France, is a foreign bill: but a bill which is drawn in London upon Edinburgh, or in Dublin, or Douglas, of the Isle of Man, upon London, is not a foreign, but an inland bill.

At what time and by what people bills of exchange were first brought into use, is a matter of history which has not been satisfactorily ascertained. The invention has been variously assigned—to the Jews and Lombards, as a mode of secretly withdrawing their effects from France and England, when, in the 13th century, they were banished for usury—to the Florentines flying from the successful faction of the Ghibellines—and to the Mongolian conquerors of China. These, however, one and all, are conjectures resting on no solid foundation. All that can be safely affirmed is, that instruments of this kind were current among the commercial states of Italy in the early part of the 14th century, and that they were not unknown about the middle of the same century in England. It has been commonly stated that the use of foreign bills preceded that of inland, and the statement, when confined to England, into which the practice was imported from other countries, is unquestionably true; but there seems no fact or reason to lead to the supposition that the original application of the invention was restricted to such uses. The object to be attained was the facilitation of exchange between parties resident at a distance from each other, by dispensing with the remittance of money in specie; and whether the parties were resident in different countries or in the same, the inconvenience would equally exist, and the remedy be equally applicable.

The history of bills of exchange would furnish much curious and instructive matter, as illustrative of the progress of trade, from the simple and somewhat clumsy operations of early times down to the refined and complicated system of modern exchanges. Originally, as has been said, they were employed solely as the means of remittance, and the exigency which brought them into use may be explained as follows:—A., at Hamburg, consigned goods to B., in London, either in execution of an order, or as his factor for sale. B., thereupon, being debtor to A. for the invoice amount, or the proceeds of the sale, as the case might be, was desirous of remitting to A. accordingly. The remittance could only be made in money or in goods; but A. might not want a return cargo of English commodities, and the sending out of specie was both inconvenient and hazardous. For, first, the proper coin was to be procured at the money-changers; next, a ship was to be found to carry it; then it was to be safely deposited on board; an

insurance, if so happy a contrivance had existed, was to be effected; and advices sent out by another vessel to A. If the ship arrived safe, there was the unloading, the carriage, and delivery on the other side; if it were wrecked or captured, there was the entire loss, when uninsured, and in case it had been insured, the trouble, still, of procuring payment. Now suppose (to take the simplest case) that some third person, C., were about to take his departure from Hamburg to London, mutual convenience would suggest the following arrangement:—A. would deliver to C. an open letter addressed to B., requesting him to pay to C. the amount intended to be remitted; and C., on receiving the letter into his possession, would pay directly to A. the value of it in money current at Hamburg, and having carried it over to London would there receive from B. the sum specified. By this simple contrivance much of the expense, and all the risk and trouble of remittance would be saved to B. or A.; and C., besides having a more convenient and portable sign of wealth, would probably receive a *bonus*, that is, some advantage for the accommodation. It is obvious, however, that to bring the machinery into operation several things would be wanting: such as, first, knowledge by both parties of the mutual want; secondly, confidence on the side of C. that the money would be paid by B. on presentment of the letter of request, or that in default of payment by B. he might safely look for reimbursement to A.; and, thirdly, the assessment of the present value of the letter, or, in other words, the determining how much C. ought to give A. in ready money of Hamburg for the sum specified in the letter, to be paid at a future day in money of England. Now one branch of this last requisite, the adjustment of the comparative value of different currencies, fell directly within the province of the money-dealers, who, from their stalls or *banques* at the great fairs and marts of exchange, received the name of *banquiers* (bankers), and as all persons about to remit or to proceed to foreign countries resorted to them for the requisite coin, they would be enabled to furnish the merchants with information as to the other particulars also, and would thus naturally become the negotiators of this sort of exchanges.

But the transactions by way of letters of exchange would have been very limited, had they depended on the occasional coincidence of a party setting out in person to the country to or from which the remittance was to be made. There were, however, other cases in which the like operation might be made available; for although A. might not want goods from England in return for those shipped by him from Hamburg, other Hamburg merchants might, and it might thus happen that, at the very time of the intended remittance, B. had money owing to him at Hamburg in respect of goods so shipped. Let it be supposed then that C., instead of setting out in person to London, were about to remit money to B., it is obvious that in that case the whole or a portion, as well of B.'s debt to A., as of C.'s debt to B., might be extinguished by a simple arrangement of the same kind as that before described. B. would write a letter addressed to C., requesting him to pay a specified sum to A., or, in mercantile phrase, would draw upon C. in favour of A.; this letter or draft he would remit, as payment, to A., who upon presentment to C. would receive from him the amount, and would give credit to B. in account accordingly.

To advance a step further, B. might not at the moment have any debtor at Hamburg through whom the substitution could be made; but as the trade between two countries is never, unless under unnatural circumstances, entirely unilateral—consisting, that is to say, solely of shipments of goods on the one part, and solely of remittances of money on the other—it would happen that if B. had not, other London merchants would have, sums of money owing from Hamburg. When therefore the convenience of this method of exchanges had been felt, it was natural that B., when desirous of remitting, should endeavour to find out some person so circumstanced, from whom he might procure an order upon his debtor; in other words, that he should buy a bill on Hamburg for remittance to A. For the reasons before mentioned, recourse would be had for this purpose to the money-dealers; and it is not difficult to conceive by what steps the business of procuring and supplying bills soon became in their hands a distinct and important branch of trade.

Nor, indeed, without the intervention of such dealers, could the system ever have become extensively useful; because although it is true, as has been said, that in the commercial intercourse of two countries it seldom happens that either is merely buyer or merely seller, it is equally rare that the value of the commodities exchanged is exactly balanced. There would consequently be at times a scarcity of bills upon one country and an excess of those upon some other. But as the system gradually matured itself, the dealers through whom the exchanges were effected would find their advantage in adjusting the demand and supply by sending or procuring the superfluous bills in one market to fill up the void in another; and would thus be enabled, in general, to furnish the required accommodation on payment of a proportionate premium.

In the meantime, the instrument of transfer, which in this country had received the name of a bill of exchange, assumed a concise and permanent form, and became clothed with such properties and incidents as experience showed to be necessary or convenient. At first, no doubt, the order was to pay on presentment to the drawee, or as it was expressed in the instrument, "on sight." But, as the intervals between drawing and presentment would necessarily be extremely variable, it

was found expedient, or it insensibly became the practice, to fix them by a definite scale; and hence probably arose what was called the *usage* between two ports or countries, being, as the name would seem to import, the period fixed by usage, at which, with reference to the date, a bill was presentable for payment. Afterwards these usances came to signify the periods at which the merchants of any particular country or port were in the practice of paying the bills so drawn upon them, and these customary periods being of course universally known among commercial men, the word *usage* soon came to signify a specific term of days, and it was formerly therefore not uncommon, when by agreement the time of payment was determined, to draw foreign bills payable at one, two, or more usances. In modern times, the more frequent practice has been to make them payable at so many days after sight, or at so many months or days after date. Again, in times when money was less at command than at present, it was but reasonable, that even after the maturity of the bill a short space should be allowed to the drawee for providing the requisite cash; and hence it became usual to grant what we term *days of grace*, which, though varying as to limits in different communities, are yet binding within the limits recognised in each community as of the law and custom of merchants.

Originally, as we have supposed, the bill was a letter addressed by B. to C., directing him to pay A. But an obvious improvement would early suggest itself, namely, that as it might not be convenient to A. to present the letter in person, he should have authority given him to appoint another, by whom the presentment might be made and the money received in his stead. It assumed therefore the form of a direction to pay A., or such person as A. should nominate and appoint, expressed with the quaint conciseness of mercantile phraseology, thus: "Pay A., or order." But if the letter or bill in the hands of A. were assignable, there was no reason why it should not be equally so in the hands of his assignee, and thus by the operation of the words "or order," it obtained the character of a negotiable instrument or sign of value, transferable from hand to hand by a simple act of delegation apparent upon some part of it. So essential to bills, and almost innate to the invention of them, does this quality now appear to be, that it excites no wonder to find it recognised by the law of some countries, such as Scotland, as a property inherent in the instrument and independent of words of transfer. In the majority of commercial countries, however, it is otherwise. In them a sagacious wisdom, or a happy accident, by making the transferability of bills dependent on the use of words of transfer, has thus enriched the world with a variety of instruments adapted to the purposes of society. A bill without words of transfer is in England not transferable, and is payable only to the payee named; one containing the words "or order," is transferable by written assignment only; whereas a bill payable to "bearer," or to "A. or bearer," is transferable from hand to hand by delivery merely. The words "or order," were no doubt the earlier form of this addition. In the case of such an instrument, the form of assignment, it may be readily conceived, would at first run in some such language as this: "Pay the within to D., or his order—signed A." and by a similar superscription D. might in like manner assign his right to E., and E. to F., and so on. But as the bill was of course *delivered* to each successive assignee, possession was of itself a sufficient voucher for payment, and the special superscription therefore being frequently dispensed with as unnecessary, the assignment of the prior holder came to be indicated by his signature alone, but with a difference of legal effect in each of these forms of assignment. For a bill under the full form is not afterwards transferable except by the written assignment of the person named; whereas the other form has the same effect of making the bill assignable by delivery without writing, as though the word "bearer" appeared in the body of the instrument. The practice of writing the assignment on the back of the instrument has given it the name of *indorsement*; and the form first described, in which the assignee is named, is termed a *special indorsement*, or an *indorsement in full*; and the mere signature of the assignee an *indorsement in blank*.

When bills were drawn payable, not as at first, on sight, but at some future day, it was natural that the first holder who had the opportunity of doing so should, during the currency of the specified period, show the bill to the drawee, and procure from him an undertaking to pay it at maturity. If he refused, the bill was protested for non-acceptance, and notice of the dishonour was immediately communicated to the drawer. If he gave the undertaking either verbally or in writing upon the bill or otherwise, he was said to have *accepted* it, and he became thenceforth liable, as the acceptor, for the amount specified; for, by the acceptance, the drawee had affirmed the right of the drawer to call upon him for payment of the money at the time specified, and he had assented to the transfer of that right, in accordance with the tenor of the instrument presented to him. If, therefore, after acceptance, he refused to pay the bill when due, he was responsible to the drawer, both in respect of his original debt and his express engagement on the instrument, and to the other parties to the bill on the contract which it contains. Such is the obligation assumed by the acceptor; but the right of the holder takes a more extensive range. For although, after acceptance, the drawee became the principal debtor, to whom therefore recourse must be had in the first instance; yet, if upon regular presentment he made default in payment, the holder was not restricted to his remedy against him alone, but might resort to all prior parties whose names appeared upon the instrument. For as the indorsement,

like the original drawing, conferred the right to receive the money, it was to be presumed that neither had been made without an equivalent, and it was but justice, therefore, that on the dishonour of the bill by the drawee, the holder should receive back the value which he had given; and as every person whose signature, whether as drawer or indorser, appeared upon the bill acknowledged himself by the act of signing to have received value for the delivery of the order, it was not unreasonable that the reimbursement should be claimed, not merely from the party from whose hands the bill had been received, but also from the drawer and every subsequent party whose name preceded that of the holder. The result therefore was this: if the drawee paid according to the tenor of the bill, the arrangement was complete, and all parties were satisfied; but if he dishonoured it, by a refusal either to pay or to accept on due presentment, a notification of the dishonour was conveyed by the holder to all parties preceding him, or to such as he thought fit to call upon for indemnity; if then the drawer paid the money, or, as it was termed, *took up the bill*, all the other parties were exonerated, and the drawer had his remedy against the drawee, upon the bill if accepted, or upon the original consideration in respect of which it was drawn, if the acceptance had been refused. In like manner, whoever satisfied the bill by payment, thereby discharged all parties posterior to himself, and obtained a right against all who preceded him. Thus each successive indorsee had the accumulated security of all the parties whose signatures were upon the instrument as acceptor, drawer, or indorser, when it came into his hands.

As bills remitted to or from places abroad are liable to be lost in their passage, it became usual, in order to obviate the inconvenience thence resulting, to draw them *in sets*; that is to say, two or more parts of each bill were drawn, and described as the first, second, third, and so on, each containing a condition that it should be payable only while the others remained unpaid. This practice of drawing in sets is made available for another purpose. The payee having indorsed and paid away one part, frequently remits another part to some agent or correspondent at the place of the drawee's residence, to be by him presented for acceptance, with a direction added, by way of memorandum, to the bill, that, when accepted, it is to be held for the use of the person who shall duly present the other part or parts for payment at maturity. The advantage of this arrangement is obvious: if the bill be accepted, it is held, according to the direction, till maturity; if refused, it is protested, and notice is given to the drawer. Upon this protest the drawer may be called upon to give security for the due payment of the bill at the expiration of its currency; or, as occasionally happens, some correspondent of the drawer at the place upon which the bill is drawn accepts it for his honour, and thereby places himself in the situation of the original drawee, being liable as acceptor to all parties subsequent to the drawer. Such an acceptance is called an *acceptance supra protest*, or *for honour*, and may be made at any time during the currency of the bill, and on behalf of any party who is liable upon it after default made by the drawee. In short, without entering into further details, by successive modifications and improvements the letter of request has become at length a very useful and convenient instrument of exchange, the operation of which as a vehicle of remittance at the present day will be apparent from the following illustration.

A person in London has a payment to make in Paris, say, for convenience, of 1000*l*. Instead of remitting the money, he goes to an exchange-broker, and purchases from him a bill on Paris equivalent to that sum. But how is that equivalent to be ascertained? or, in other words, for what amount in French money is the bill to be drawn? In the determination of this question there are several items of calculation. The bill will be payable in France; how many francs then are equal to 1000*l*. By the mint regulations between England and France, 1*l*. sterling of English money is equal to 25 francs 20 cents, which is therefore the nominal or standard *par* of exchange between the two countries. According to this scale, then, 1000*l*. in London would be worth 25,200 francs in Paris. But the *par* is fixed on the supposition that the currencies of the two countries respectively are uniformly of the weight and purity established by the Mint; whereas, not unfrequently, the coin is debased by alloy or attrition, and the relative value undergoes a corresponding alteration. This deviation however is well known, and may be regarded as comparatively constant. But there are other circumstances affecting the ratio of value of a more fluctuating and unsteady operation. When, for instance, any considerable portion of the circulating medium of either of the two countries between which the exchange is to be effected consists of a paper currency, the standard is materially affected by the quantity of paper in circulation. Without entering into an exposition of the law of this variation, it is sufficient to remark, that a redundancy of paper money has invariably the effect of depreciating the standard, or, in other words, of raising the value of the *standard coin* as compared with the same nominal sum in *paper money*. This effect is temporary only when the paper is convertible into specie on demand; if inconvertible, it is both permanent and considerable. Thus it is well known that, at one period during the war which followed the first French Revolution, the English guinea was worth 26*s*. in money, estimated according to the value of the 1*l*. sterling in bank notes. At that time therefore the English pound would fall far below the Mint standard of 3*l*. 17*s*. 10½*d*. per ounce, and a proportionate effect would be produced on the rate of exchange with any

other country in which the standard was maintained. Taking, as before, the instance of France, the par would vary, other things remaining constant, from 25 francs to somewhere about 19 francs, or 1000*l.* in a Bank of England note would buy a bill on Paris, not for 25,200 francs, but for about 19,000 francs only. But it is evident that the same cause might be operating in a greater or less degree in France also, in which case the calculation would be still further complicated by a comparison of the depreciation in the one country with that in the other. The variation here taken for an example is of course an extreme case, but fluctuations the same in kind, though less in degree, are still of continual occurrence, and must be carefully taken into account in all calculations as to the price of bills.

But besides these monetary influences on the nominal par, there are other causes in operation which materially affect the rate of exchange, and by consequence the price of bills. The accommodation of a remittance in the form of a bill of exchange is worth a calculable sum, the maximum being the compound of the labour, expense, and risk of the transmission of money in specie. Suppose this maximum to be one per cent., it is evident that it is worth the while of the remitter to pay any sum short of 10*l.* for the purchase of a bill equivalent to 1000*l.* Now the market price of bills, like that of every other commodity, is mainly dependent on the relation of the supply to the demand, and this again is primarily regulated by the state of trade between two given countries. When the value of the exports to any country in a given period is equal to the value of the imports from the same country in the same period, the trade is said to be balanced; the bills drawn in each country upon the other will be equal in amount, and this equilibrium constitutes what is called the *real* par of exchange. But it is obvious that this state of things can never actually exist, that it is the point on each side of which the exchanges will continually oscillate, and at which they will never rest. Even where, upon the average of years or months, the trade is nearly even, there will be disturbing circumstances which will have a temporary effect upon the exchanges. There will consequently be occasional scarcity and occasional abundance of foreign bills in the market. When scarce, their price of course is higher, or, as it is ordinarily expressed, they bear a *premium*. At such times the imports exceed the exports, and the exchanges are said to be *against us*. Suppose that, in the trade between England and France, the value of our imports from France exceeds that of our exports to France by about three-fourths. The effect of this, if matters were left to themselves, would be, that of the remittances to France three-fourths must be made in specie, and that the bills in which the remaining one-fourth was made would be at the maximum price; that is to say, taking the scale before adopted, would bear a premium of all but one per cent. But it is a fact, incontestably established, that in every trading community the value of the whole of the exports taken together is, upon an average, very nearly balanced by the value of the whole of the imports, or, in other words, that ultimately all commodities imported are paid for directly or indirectly in commodities exported. Necessarily, therefore, the bills drawn in England upon foreign countries, say in one year, nearly balance the bills drawn in foreign countries upon England in the same period. Thus, to take a familiar instance, although there may be a deficiency in London, to the extent of three-fourths, of bills upon France, there may be an excess, in nearly the same ratio, of bills upon Belgium, and in like manner there may be an excess in Belgium, to the same extent, of bills upon France. Acting on the knowledge of this fact, the London bill-merchant, by means of his agent, will buy bills upon Paris at Antwerp, where they are cheapest, and bring them for sale to London, where they are dearest. The cost of procuring, and the profit of the bill-merchant, therefore, upon this transaction, constitute the third element in the calculation. Supposing then the bill to be a *good* one,—that is to say, guaranteed by names of known and established credit, the only remaining operation is to estimate the discount according to mercantile practice, or, in other words, the interest of 1000*l.* in money for the time which will elapse before payment of the bill; and the combined result will give the sum in francs for which the bill is to be drawn, or the amount of bills already drawn to be given in exchange for 1000*l.*

The same remarks, *mutatis mutandis*, are applicable, if instead of a remittance to Paris a sum of money was to be received from thence; for the mode adopted would be this. The party in London would draw a bill upon his debtor in Paris, for which the exchange-broker would immediately give him the value, ascertained as before, either in cash or in bills upon London, or in both; and although the system, as here explained in detail, may seem, as in truth it is, of some complexity, yet practically the price, like that of every other commodity, readily adjusts itself. In London it is the practice for the bill-brokers to go round to the principal merchants and inquire whether they are buyers or sellers of bills. The relation of supply and demand being thus ascertained, a few of the most influential merchants settle the average price at the Royal Exchange; and a document known as 'Wetenhall's List' contains the record of rates according to actual transactions. By these means the value of particular bills, varying of course according to the credit of the parties to them, or, as it is generally called, *the goodness of the names*, is easily determined.

Bills of exchange are also in frequent use for the purpose of remittance from one part of the United Kingdom to another. Thus the trader in Manchester, Leeds, or Birmingham, who has a payment to

make in London, remits bills of his customers in the country. These are discounted by the monied capitalists through the intervention of bill-brokers. A few of the London bankers also discount for the accommodation of their customers, and the Bank of England deals extensively in that department. The bills so cashed are transmitted to the provincial banks to be presented at maturity for payment. Conversely, in the provincial towns the country bankers discount bills on London, and transmit them to their correspondents there for payment. The rate of discount varies according to the demand for money, and the character of the particular bills; but it is seldom, upon regular transactions, more than five, or less than two and a half per cent.

Hitherto bills of exchange have been considered, in their primary application, as means of remittance, but there are other purposes equally important, which, by an intelligible transition, they have been made to serve. For, the use and properties of bills being once understood, and their validity recognised, nothing was more natural than that they should be applied to the ordinary transactions of trade. A trader desirous of purchasing a commodity for which his available funds might not enable him to pay ready money, would tender to the seller an order for payment on some other person, receiving or paying the difference, as the case might be, and making an allowance by way of interest, or, which is the same thing in other words, paying an extra price, in proportion to the time of the bill's currency. To the seller this mode of dealing would obviously be better than the giving of a naked credit, as affording him an additional chance of payment, and a written acknowledgment of his debt. Moreover, when the negotiability of inland bills was once admitted, they would serve all the purposes of actual money, because in the same manner as the original seller had been induced to take the order in payment, another might be willing to receive it from him in the purchase of other commodities; or it might be at once discounted or converted into cash by application to a money-dealer, whether bill-broker or banker, in the manner which has been already explained in speaking of remittances.

But the drawing of a bill supposes, as has been said, that the drawee either has in his possession funds of the drawer, or is his debtor to the amount specified in the order; it was therefore by an easy step that in the transactions of wholesale dealing it became a common practice for the seller to draw upon the buyer, for the price of the goods, a bill payable to his (the seller's) own order at some future day. This bill the buyer immediately accepted, and thus in effect acknowledged himself to be the debtor of the drawer to the amount specified, and engaged to pay the holder at maturity. By this arrangement, now very general, the buyer obtains credit for the term at the expiration of which the bill is made payable, and the seller has the advantage of a fixed day for payment being named in the bill, and a means of procuring cash if he chooses to negotiate the bill.

Neither was it an unreasonable extension of the principle that a bill should be drawn and accepted *on the faith of funds to be received by the drawee* at or before the maturity of the draft. At the present day this practice prevails to a great extent, and may be illustrated by a supposed case as follows:—There are established in most if not all the principal trading ports of the world, merchants who carry on the business of general factors or agents for sale, and whose establishments are known among mercantile men under the name of commission-houses. The course of dealing with such houses is, for the most part, this:—A., a manufacturer at Manchester, consigns a cargo of cotton pieces to B. and Co., a commission-house at Mexico, for sale on his account. The English correspondents of B. and Co. are Messrs. C. and Co. of London. By an arrangement among these several parties A. draws on C. and Co. for half or two-thirds, as may be agreed, of the invoice price of the goods consigned, and discounting the bill with his banker obtains at once an instalment in actual money, which immediately returns into his capital, and becomes useful in producing more goods and creating more wealth. Ultimately, account sales are furnished by the Mexican house, and A. again draws on C. and Co. for the balance, if in his favour. Annual balances are struck between B. and Co. and C. and Co., and remittances by bills for the adjustment of the account complete the transaction. The advantages of this anticipatory part-payment are obvious, more especially in the trade with distant countries, such as South America or the East Indies. But the practice has degenerated into something of an abuse. It has of late been the frequent practice of the consignors of goods to make out invoices with prices artificially high, and so to procure a remunerating return even from the proportion for which they are authorised to draw in advance. The effect is to throw upon the consignees the whole risk, which was formerly shared between the two, and proportionately to impair the steadiness and security of commerce.

Perhaps, however, if this were the only abuse of bills, there would be little to complain of—nothing, certainly, to counterbalance the immense advantages which are derived from them as instruments of exchange; but, unfortunately, of late years, the abundance of money in the English market, and the consequent facility of negotiating paper securities, the competition of trade, and the accompanying relaxation of the system of credit, with other causes which will readily suggest themselves, have given occasion to practices which are not only a wide departure from the original purposes of bills of exchange, but are most injurious to the general interests of trade. Good bills, we have

said, may be always discounted. Accordingly, any man whose credit is good may at any time raise money upon a bill drawn, accepted, or indorsed by himself. If his credit be doubtful he may still procure cash by the same expedient, paying, however, a premium or rate of discount proportioned to the increased risk. Among needy men instances are not unfrequent of discounts procured by these means even at the exorbitant rate of 20 or 30, sometimes even 70 per cent. But a still more common practice is the negotiation of what are called by the significant name of *accommodation bills*. A trader unable to meet his liabilities applies to a friend whose credit is better than his own, to accept, or in some other way to become a party to, a bill concocted for the purpose, undertaking to provide the funds necessary for paying it when due, and generally giving in return his own acceptance of another concocted bill, known in the mercantile world as a cross acceptance. When one or more names have thus been obtained sufficient to give currency to the bill, it is discounted, and the money applied to the necessities of the trader. As this bill falls due, the same operation is repeated, until the system of expedients failing at last, as sooner or later it inevitably must, the ruin of the insolvent trader himself is consummated, and not unfrequently draws along with it others who, unfortunately or imprudently, may have become parties to these unsubstantial representatives of value. Of the more serious mischiefs of this dangerous practice, such as the temptation to forgery by the use of fictitious names as drawers or payees, it is perhaps useless to speak, because few men at first seriously contemplate the commission of a crime, but are rather drawn into it by circumstances not foreseen or not appreciated; but the reflection that it is a foolish and improvident practice—that, in addition to the loss of credit, which, once perceived (and how can it fail to be perceived?), it is sure to occasion, there is the certain expense of stamps and higher rates of discount, and moreover a *double liability* in respect of every shilling for which cross acceptances are given—may perhaps have some effect in deterring honest men, however necessitous, from having recourse to this fatal expedient.

The various uses to which bills of exchange are made applicable in the great community of commerce having been thus explained, it remains only to take a glance at their legal incidents as instruments of contract.

In contemplation of law a bill of exchange, as well in its original formation as in its successive transfers, is an assignment of a debt, by which the right of the original creditor to sue for and obtain payment is transferred to the holder for the time being. In such a substitution the Roman law saw nothing objectionable; and in those countries, therefore, which adopted the civil law for their own, the negotiation of bills found no impediment. But into the common law of England had early been incorporated a doctrine, founded probably on experience of the mischief, that the assignment of a mere right such as a debt would give, being in truth the assignment of suits at law, which might be converted into an engine of oppression, was illegal and void. Bills of exchange, coming within the meaning of this doctrine, must have been extinguished by the courts of law. But, fortunately for England, the opportunity seemed not to have arisen till the danger was past: for although we have unequivocal mention of these instruments in our statute book as early as A.D. 1379 (3 Ric. II. c. 3), no case upon them before the courts is to be met with in the reports earlier than the time of James I. In the 17th century merchants had acquired a prescriptive right to the customs which they had been observing during the long interval; and these customs, including the use of negotiable bills of exchange, and forming together the law-merchant of this country, came to be received as parcel of the common law of the land. There was still, however, a reluctance in the courts of law to admit that any one but a merchant could be a party to these instruments, or that even merchants could make an inland bill in the absence of long precedent amounting to prescriptive custom in its favour; but the courts, after a short resistance, were obliged to yield both points to the convenience and necessities of modern society.

In respect of their transferability, bills of exchange long stood alone among contracts. By another property as remarkable, which they derive also from the custom of merchants, they are still distinguished from all other instruments, not under seal, known to the English law. It is a presumption of law in their favour, that these instruments are honest in their inception, and have been founded originally and transferred since upon valuable consideration; so that whilst good consideration must be proved by every one who seeks to enforce any other contract not under seal, the holder of a bill of exchange is presumed to be a holder for value, until his opponent proves the contrary, or rebuts the presumption by such a *prima facie* case of fraud as puts the holder upon proof of his title to recover.

Of the Parties to a Bill.—Any person, whether trader or not, who is not under a legal incapacity to contract, may become party to, and thereby liable upon, a bill of exchange. Infants and married women are not personally bound by becoming parties; but the instrument, though inoperative as against them, may be available against others whose names are upon it. A person may become party to a bill, not only by his own act, but by that of his duly authorised agent. The agent ought either to sign the name of his principal without anything further, or to add to his own signature the words "per procuration for A. B.," or to make it in some way apparent upon the face of the

instrument that he acts *as agent*. Otherwise, though really an agent, he renders himself personally liable by his signature, and exempts his principal. Any one who assumes to draw, accept, or indorse by procuration, knowing that he has no authority to do so, though without any intention of committing a fraud, is, upon default by the person whose authority is assumed, liable, though not upon the bill as a party, yet to a special action for deceit at the suit of a *bona fide* holder, or for a breach of the implied warranty that he had authority as agent to make the contract.

Each member of a trading firm, in whose business bills are usual or necessary, has an implied authority to bind his copartners by drawing, accepting, or indorsing bills, provided such bills are not joint and several: but this presumption of authority fails where the holder has covinously colluded with a partner to make the partnership funds or credit available for his own individual purposes. The acceptance of a bankrupt partner in the name of the firm, though after a secret act of bankruptcy committed by that partner, is an available security in the hands of a *bona fide* indorsee for value.

Joint-stock companies under the 19 & 20 Vict. c. 47, may become parties to a bill by any person, who has express or implied authority of the company for that purpose, making, accepting, or indorsing such bill in the name of the company; but as the word "limited" is an essential part of the name of a company formed with a limited liability, any bill issued without that word is not binding on the company; and the person who signs or issues the bill in this imperfect state incurs a penalty of 50*l.* and personal liability to the holder on the bill.

Of the form and other requisites of a bill.—A bill of exchange must be in writing, but no precise form of words is essential to its validity. The only requisites are that it be an order for the payment of money simply, and not for the payment of money and the performance of some other act; that it be for a sum of money certain; that it be payable at all events, and not upon a contingency, or out of a particular fund; and that the person to whom, and the person by whom, it is payable be ascertained absolutely on the face of the instrument. The forms in ordinary use are as follows:

Form of a Foreign Bill in sets.

No. London, 1st Jan. 1859.
[Stamp.] days after sight (or days after date, or at
usances) pay this my first of exchange, second and third of the same
tenor and date not paid, to Messrs. A. B. and Co., or order, ten
thousand francs value received of them, and place the same to
account. C. D.
Mr. E. F., Paris.

Form of an Inland Bill.

[Stamp.] London, 1st Jan. 1859.
£100. months after date (or "at sight," or days after date)
pay Mr. A. B., or order, one hundred pounds for value received.
To Mr. E. F., Castle-street, Liverpool. C. D.

To take the several parts of this form in their order:

All inland bills, and such foreign bills as are drawn in England, are liable to a duty, and must be made on paper duly stamped, under a penalty of 50*l.*, with this further consequence, that the bill, though otherwise complete, is absolutely worthless if not on stamped paper. Foreign bills not drawn in England are of necessity excluded from the operation of this statute. But another statute requires that all such bills as have been, or purport to be, drawn abroad, shall be stamped with the proper adhesive stamp (the same to be cancelled with the name of the holder or his firm, and the day and year of his doing so,) by the holder before he shall present them for payment, or indorse, transfer, or otherwise negotiate them within the United Kingdom, subject to a penalty of 50*l.* And any person who takes such a bill without the requisite stamp affixed and cancelled, shall not be entitled to recover on it, or to make it available for any purpose whatsoever.

For inland bills, and for foreign bills drawn in the United Kingdom, and singly or otherwise than in a set of three or more, the scale is as follows:

£	Not above	£	£ s. d.
Above	5 and not above	5	0 0 1
"	10	10	0 0 2
"	25	25	0 0 3
"	50	50	0 0 6
"	75	75	0 0 9
"	100	100	0 1 0
"	200	200	0 2 0
"	300	300	0 3 0
"	400	400	0 4 0
"	500	500	0 5 0
"	750	750	0 7 6
"	1000	1000	0 10 0
"	1500	1500	0 15 0
"	2000	2000	1 0 0
"	3000	3000	1 10 0
"	4000	4000	2 0 0
"	4000 and upwards		2 5 0

For foreign bills, drawn in sets of three or more, the scale is

For every bill of each set, if the sum is			
	£	£	£ s. d.
	Not above	25	0 0 1
Above	25 and not above	50	0 0 2
"	50	75	0 0 3

"	1000	1500	0 5 0
"	1500	2000	0 6 8
"	2000	3000	0 10 0
"	3000	4000	0 13 4
"	4000 and upwards		0 15 0

A bill altered in any material respect after it has been once issued is in effect a new bill, and the existing stamp was exhausted by the unaltered bill. No action can be maintained in any court of law or equity upon a bill not having the proper stamp as well in denomination as in value.

A date, though usual, is not essential to a bill, unless drawn for a sum under 5*l*. When no date is given, the bill is presumed to be dated when drawn.

A bill in which no *time of payment* is expressed is construed to be payable on demand.

Bills, as has been said, are ordinarily made *payable* to some third person, or to the drawer himself. They may, however, be expressly made payable to bearer, and when a fictitious name is given as payee, the instrument is in legal effect payable to bearer, as against the co-concoeters of the instrument and in favour of an innocent *bond fide* holder. But certainty as to the person to whom it is payable is essential to the validity of the bill, and such a bill as is payable to the secretary for the time being of a specified society is void. It must be observed that the inserting a fictitious name as payee and indorsing the bill with that name is a forgery, and punishable as such.

The words "*or order*" give to the bill its character of negotiability, but the general operation of this expression may be restricted by the payee or any other indorser, who, by the following simple form of indorsement, "*Pay A. B. (or A. B. or order) to my use,*" may cast upon the next immediate holder the responsibility of seeing that the contents are duly applied.

The *sum* should be clearly expressed in the bill, and in such way as to render forgery difficult. But a blank draft or acceptance given to a third person may be filled up by him with any sum which the stamp will cover.

"*Value received*" upon a bill signifies, in general, value received from the payee, and the bill itself without these words imports so much. A *total* want of consideration is ground of defence to an action upon the bill as between immediate parties, but is not available as an answer to the claim of a holder for value who has taken the security in the regular course.

An alteration in a bill in any material part, as in the date, sum, or time when payable, will, independently of the stamp acts, render the bill wholly invalid as against any party not consenting to the alteration, and this although it be in the hands of an innocent holder. But an alteration in a part not material, or made merely for the purpose of correcting a mistake, in furtherance of the original intention of the parties, though made after the bill is complete, will not invalidate it, either as regards the stamp laws or otherwise.

Of the delivery of the bill to the payee.—The delivery of a bill of exchange in consideration of an antecedent debt suspends the right to sue for that debt during the currency of the bill; but if it be dishonoured at maturity, the original debt revives, and with it the legal remedy, provided that no act be done by the holder to prejudice or impair the claim of the drawer upon the acceptor. In like manner the taking of a bill of exchange in payment suspends for the time the lien of a seller upon goods sold and remaining in his possession; but if the bill be not paid when due, he is remitted to his right of retaining or stopping the goods before they reach the buyer.

Of the presentment, acceptance, and non-acceptance of bills.—It is usual, as already said, for the payee, or the first holder who conveniently can do so, to present the bill to the drawee for acceptance; and when a bill is drawn payable at a certain time after sight, presentment for acceptance is necessary in order to fix the date of payment, and ought to be made within a reasonable time. A foreign bill so drawn may be *circulated* for a reasonable time before acceptance, and an inland bill may also be put into circulation, though with less latitude as to time; but in either case, if the payee *keep the bill in his possession* for a longer time than is reasonable, he is guilty of *laches*, and cannot recover against the drawer.

The presentment should in all cases be made during the usual hours of business, and to the drawee himself or his agent, who is bound to return an answer within twenty-four hours.

The acceptance of any bill, whether foreign or inland, must by the law of the United Kingdom be in writing on the bill, or if there be

more than one part, on one of the parts of the bill, and signed by the acceptor or some person duly authorised by him.

An acceptance may be either absolute, conditional, partial, or qualified.—An absolute acceptance is an engagement to pay the bill according to the tenor: a conditional acceptance may be to pay the bill upon a contingency; as that the drawee will pay when certain goods shall be sold, or when certain funds shall come to his hands, or the like, and in this case the acceptor is not bound until the fulfilment of the condition.

A bill may also be accepted *partially*, as to pay a sum short of that for which the bill is drawn. In all cases of a conditional or partial acceptance, the holder ought to give notice thereof to all parties whom he intends to hold liable on default.

An acceptance may also be qualified as to the time of payment or the place of payment; but in the case of inland bills a special acceptance as to the place of payment can only be made by the use of restrictive words: as for instance, "Accepted payable at Coutts & Co., and *not elsewhere*."

If the drawee refuse or neglect to accept, any third party, after protesting the non-acceptance by the drawee, may accept for the honour of the drawer or any subsequent party, and such an acceptance is called an acceptance *supra protest*, or *for honour*.

Upon the non-acceptance of a foreign bill, a protest is made by the holder before a notary public; and this protest by the custom of merchants, is become so indispensable that neglect of it by the holder will prevent him from recovering against the other parties to the bill. Inland bills need not be protested, and in practice are merely noted for non-acceptance, which itself also is a useless form.

Notice of the non-acceptance must be given with all diligence to every party to whom it is intended to resort for payment; and the want of such notice, or the delay of it beyond the time allowed by law is a discharge of all parties, who have not received due notice, from their liability. This is the law—with regard to the drawer, on the ground that he is prejudiced by not receiving immediate information of the default, so as to enable him to withdraw his effects from the hands of the drawee;—and with regard to the indorsers, for a similar reason, inasmuch as their interests may be affected by the delay. If the drawer had in truth no effects in the hands of the drawee, or no reasonable expectation that there would be effects in the drawee's hand before the maturity of the bill, or no remedy over against some other party to the bill, the omission to give the drawer notice constitutes no objection to the right of action as against him. Generally, to be quite safe, notice should be given within twenty-four hours after the dishonour, and each party on receiving such notice is allowed the same interval for communicating to those who precede him upon the bill. But no more time is allowed for giving a large number of notices than is allowed for one. And where the parties to receive it live at a distance from the party who gives notice, it suffices to *despatch* it within the time specified; but if both parties live in the same town it should be despatched so as to *reach* the other within that time. The notice may in all cases be sent by the post, and it is sufficient to show that the letter containing it was delivered into the post-office.

The death, known insolvency, or even bankruptcy of the drawee, affords no excuse, either at law or in equity, for a neglect to give due notice of non-acceptance; but any party may, by agreement, or by a subsequent admission of his liability, dispense with or waive the notice to which he is entitled; and where the residence of the party is unknown, due diligence to discover it is all that the law requires.

Of the indorsement and transfer of bills, something has been already said. No form has been prescribed by the law for the mode of indorsement, and in general the mere signature of the party is sufficient. After an indorsement in full, the holder can derive title only through the special indorsee, whose signature therefore must appear upon the bill.—An indorsement is valid though made after the bill is become due, but the holder in that case is entitled only to such advantages as might have been claimed by the last indorsee before maturity, and is liable to such counter claims as might have been set off against him.

After payment of a part, the bill may be indorsed over for the residue. Bills payable to bearer may be transferred by delivery only without indorsement. An indorsement may be restricted by the words before mentioned, "*Pay A. B. to my use,*" or by any other expression clearly limiting the authority to assign.

A *bond fide* holder for value is not affected by the want of title in any previous indorser; and nothing but *mala fides* can invalidate his title, notwithstanding that the bill may have been lost or stolen from the possession of a rightful owner.

If a bill is not negotiable and has been lost or destroyed, the payee may nevertheless recover at law against the acceptor or drawer. If a negotiable bill has been lost or destroyed the rightful owner may offer an indemnity and recover against the party liable either at law or in equity; but if the rightful owner wishing to enforce payment, refuses to give an indemnity, the defendant may defeat the action at law by setting up the loss or destruction of the bill, or he may compel the other in equity to give him an indemnity and cast him in the costs of the suit.

Of the presentment for payment, &c.—The holder of a bill is bound to present it to the drawee for payment at the time when due, when a

time of payment is specified, or within a reasonable time after receipt of the bill when no time is expressed. If he neglect to do so, not only is he disabled from afterwards resorting to the drawer or indorsers—whose implied engagements are severally to pay only in case of default by the drawee, and who are always presumed to have sustained damage by such neglect on the part of the holder—but he loses also his remedy for the consideration or debt in respect of which the bill was given or transferred. As in the case of presentment for acceptance, so in that of presentment for payment, the insolvency of the acceptor does not dispense with the presentment for payment, as regards the drawer and indorsers: but to an action against the acceptor presentment is not a necessary preliminary, unless the bill has been accepted payable at a particular place *only* and *not elsewhere*; and then presentment is indispensable to charge even the acceptor. If the acceptance be qualified in this way as to the place of payment, the presentment must be made at the place so specially indicated; but in general, a presentment at the domicile of the drawee is sufficient, even though another place be named upon the bill. The presentment ought to be made on the last of the days of grace, unless that be a Sunday or holiday, and in that case on the day preceding. Bills payable on demand, or where no day of payment is expressed, are not entitled to days of grace.

The following is a statement (taken from Chitty on 'Bills of Exchange,' 10th edit.) of the usance and days of grace for bills drawn in London upon some of the chief commercial cities.

m. d., m. s., d. d., d. s., d. a., respectively denote months after date, months after sight, days after date, days after sight, days after acceptance:

London on.	Usance.	Days of Grace.

Trieste	14 <i>d. a.</i>	3
Venice	3 <i>m. d.</i>	6
Vienna	14 <i>d. a.</i>	3

It should be remarked, however, that many of these usances are obsolete in the strict sense of the word; and the same remark applies to days of grace. In England three days of grace are allowed and always taken, so that bills are not presentable for payment until the three days are expired.

In general, payment made on any part of the day on which the bill is presented will be sufficient; yet if payment be once refused, however early in that day, the bill is effectually dishonoured by such refusal, and recourse may be at once had to the other parties. The requisites, with respect to notice, protest for non-payment, and payment *supra protest*, &c., are the same as those which have been already given under the head of presentment for acceptance. In this country no damages are recoverable upon inland bills dishonoured, the party sued being liable only for the amount of the interest to the day on which judgment is entered up. On foreign bills duly protested the expenses occasioned by the dishonour, as re-exchange, postage, and commission, unless where a liquidated sum is agreed on between the two countries to cover all expenses in such cases, may be recovered under the name of damages, and amount sometimes to a considerable sum. But neither in this country nor in any other can compensation be claimed by the holder for losses more remotely consequential, as the expense of travelling or the disappointment of some profitable adventure.

If the holder make any agreement with the acceptor for taking a

composition from him, or limiting a time within which he will not press for payment, all the other parties to the bill, being in the situation of sureties only, are exonerated from their liability by this dealing with the principal.

Payment should be made only to the person who is able to give a discharge upon the bill; and it may be refused unless the bill be delivered up. It is usual moreover and prudent to take a receipt written on the back. If payment be made by mistake, as upon a forged acceptance, indorsement, or the like, the money so paid may be recovered back from the holder, provided the discovery is made, and notice given to the holder, on the day on which the payment is made.

The forgery of a bill of exchange or of any signature thereto, as well as the uttering of any such forged bill or indorsement with a knowledge of the forgery, is a felony, punishable with transportation or penal servitude for life, or for not less than four years, and with imprisonment and hard labour not exceeding four years. (See Chitty on *Bills of Exchange*, 10th edit., by John A. Russell, LL.B., and David MacLachlan, M.A.; Byles on *Bills of Exchange*; Blackstone's *Commentaries*, by R. M. Kerr, LL.D.)

BILL OF EXCHANGE IN SCOTLAND. The general law on the subject is the same in Scotland as in England, with few exceptions. In Scotland it is not held that to make a bill negotiable, it must contain negotiable words; and the laws restricting the negotiation of bills under 5*l.* does not apply to that part of Great Britain. It is usual, there, to protest both foreign and inland bills, both for non-acceptance and non-payment. When protest has been duly taken and recorded, and when the other requisites of negotiation are complied with, and there is no flaw on the face of the bill, execution may be issued immediately against the parties liable, by what is called "summary diligence," as if it were the decree of a court. This execution may be suspended, on good cause for so doing being stated, and on security being given, or the amount brought into court when these conditions are imposed.

BILL OF HEALTH. [QUARANTINE.]

BILL OF LADING, an acknowledgment signed usually by the master of a trading ship, but occasionally by some person authorised to act on his behalf, certifying the receipt of merchandise on board the ship, and engaging, under certain conditions and with certain exceptions, to deliver the said merchandise safely at the port to which the ship is bound, either to the shipper, or to such other person as he may signify by an endorsement upon the Bill of Lading.

The conditions stipulated on behalf of the master of the ship are, that the person entitled to claim the merchandise shall pay upon delivery of the same a certain specified freight, together with allowances recognised by the customs of the port of delivery, and known under the names of *primage* and *average*. *Primage* amounts in some cases to a considerable per centage (ten or fifteen per cent.) upon the amount of the stipulated freight, but the more usual allowance under this head is a small fixed sum upon certain packages, for example, the *primage* charged upon a hogshead of sugar brought from the West Indies to London is sixpence. This allowance is considered to be the *perquisite* of the master of the ship. *Average*, the claim for which is reserved against the receiver of the goods, consists of a charge divided *pro rata* between the owners of the ship and the proprietors of her cargo for small expenses (such as payments for towing and piloting the ship into or out of harbours), when the same are incurred for the general benefit.

The exceptions stipulated on behalf of the shipowners are stated in the Bill of Lading, which is usually drawn up in the following words:—

"Shipped, in good order and well conditioned, by [John Smith], in and upon the good ship called the [Mary], whereof is master [Thomas Jones], now lying in the [River Thames], and bound for [Hamburg]

[1 S 1 at 100 Bags
,, 1 at 7 Chests]

[One Hundred bags of Coffee, and
Seven Chests of Indigo.]

marked and numbered as in the margin, to be delivered in the like good order and condition at the aforesaid port of [Hamburg] (*the act of God, the Queen's enemies, fire, and all and every other danger and accidents of the seas, rivers, and navigation, of whatever nature and kind soever excepted*) unto [Messrs. Schröder and Co.] or their assigns, they paying freight for the said goods at the following rates, namely, [One Shilling and fourpence sterling per Hundred Weight for the Coffee, and five-eighths of a penny sterling per pound for the Indigo], together with *primage* and *average* accustomed. In witness whereof, I, the said master of the said ship, have affirmed to [four] bills of lading, all of this tenor and date, any one of which bills being accomplished, the other [three] are to stand void. Dated in London, this [first] day of [June] 1859.

"Thomas Jones."

In every case where shipments are made from this country, one at least of the bills of lading must be written upon a stamp of the value of sixpence.

One of the bills (unstamped) is retained by the master of the ship, the others are delivered to the shipper of the goods, who usually transmits to the consignee of the goods one copy by the ship on board which they are laden, and a second copy by some other conveyance. In

case the ship should be lost, when the goods are insured, the underwriters require the production of one of the copies of the Bill of Lading, on the part of the person claiming under the policy of insurance as evidence at once of the shipment having actually been made, and of the ownership of the goods.

Considerable hardship was experienced up to a late period from the state of the commercial law of England as regarded pledges. A factor to whom consignments of goods should be made had full power over those goods to sell them, with or without, or even against, the instructions of the owner, but he had no right to pledge them, and if he did so the owner of the goods might insist upon their restitution from the pawnee without repaying the advances he might have made. It was impossible to know from the terms of the document whether the holder of a Bill of Lading was actually the owner of the goods represented by it, or only entrusted with them as a factor, and cases of great hardship frequently occurred, sometimes indeed not without suspicion of collusion between the owner and the factor. This law was defective, because it visited upon a third party the carelessness or error of the owner of the goods in making a false estimate of the character of the factor whom he employed, and because, on the other hand, it frequently compelled factors to sell goods at an unfavourable moment, the necessity for which course might have been averted, if they could legally have given the goods in security for an advance of money. This state of things was remedied by the statute 6 Geo. IV. c. 94, usually called "the Factor's Act," which was subsequently amended by stat. 5 & 6 Vict. c. 39. Any person in possession of a Bill of Lading is now deemed the true owner of the goods specified in it, so as to make a sale or pledge by him of such goods or bill of lading valid, unless the person to whom the goods are sold or pledged has notice that the seller or pledger is not the actual and *bona fide* owner of the goods.

The unavoidable practice of delivering more than one bill of lading as an acknowledgment for the same goods (of the shipment of which the bill of lading is as against the master conclusive evidence), makes it necessary to protect the master against demands made for the delivery of the goods in the possible case of different copies of the Bill of Lading falling into the possession of different persons. In such case all that is required from the master is, that he, acting in perfect good faith, and without any reasonable suspicion of fraud on the part of the person first making the demand for delivery, shall comply with the same to the person so first demanding the goods by the presentation of the Bill of Lading. The property in the goods represented by a Bill of Lading, and all the rights and liabilities of the parties thereto, *inter se* (18 & 19 Vict. c. 111), can be assigned like a bill of exchange by indorsement, which may be either in blank or special. In the event of the first mode being used, as the document might accidentally fall into improper hands—a fact which the master of a ship could not reasonably be expected to discover—he is free from responsibility when acting without collusion. Should he, on the other hand, act either negligently or collusively in the matter, the law will compel him to make good their value to the real owner of the goods.

BILL OF RIGHTS is the name commonly given to the statute 1 William and Mary, sess. 2, chap. 2, in which is embodied the Declaration of Rights, presented by both Houses of the Convention to the Prince and Princess of Orange, in the Banqueting House at Whitehall, on the 13th of February, 1689, and accepted by their highnesses along with the crown. The Bill of Rights was originally brought forward in the first session of the parliament into which the Convention was transformed; but a dispute between the two Houses with regard to an amendment introduced into the bill by the Lords, naming the Princess Sophia of Hanover and her posterity next in succession to the crown after the failure of issue to King William, which was rejected in the Commons by the united votes of the high church and the republican parties, occasioned the measure to be dropped, after it had been in dependence for two months, and the matter of difference had been agitated in several conferences without effect. The bill was however again brought in immediately after the opening of the next session, on the 19th of October, 1689, and the amendment respecting the Princess Sophia not having been again proposed, it passed both houses, and received the royal assent in the same shape in which it had formerly passed the Commons, with the addition only of a clause inserted by the Lords, enacting that the kings and queens of England should be obliged, at their coming to the crown, to take the test in the first parliament that should be called at the beginning of their reign, and that if any king or queen of England should embrace the Roman Catholic religion, or marry with a Roman Catholic prince or princess, their subjects should be absolved of their allegiance. This remarkable clause is stated to have been agreed to without any opposition or debate.

The Bill of Rights, after declaring the late King James II. to have done various acts, which are enumerated, utterly and directly contrary to the known laws and statutes and freedom of this realm, and to have abdicated the government, proceeds to enact as follows:—

"1. That the pretended power of suspending of laws, or the execution of laws, by regal authority, without consent of parliament, is illegal. 2. That the pretended power of dispensing with laws, or the execution of laws, by regal authority, as it hath been assumed and exercised of late, is illegal. 3. That the commission for creating the

ARTS AND SCI. DIV. VOL. II.

late court of commissioners for ecclesiastical causes, and all other commissions and courts of like nature, are illegal and pernicious. 4. That levying of money for or to the use of the crown, by pretence of prerogative, without grant of parliament, for longer time, or in other manner, than the same is or shall be granted, is illegal. 5. That it is the right of the subjects to petition the king, and all commitments and prosecutions for such petitioning are illegal. 6. That the raising or keeping a standing army within the kingdom in time of peace, unless it be with consent of parliament, is against law. 7. That the subjects, which are protestants, may have arms for their defence, suitable to their condition, and as allowed by law. 8. That election of members of parliament ought to be free. 9. That the freedom of speech, and debates or proceedings in parliament, ought not to be impeached or questioned in any court or place out of parliament. 10. That excessive bail ought not to be required, nor excessive fines imposed, nor cruel and unusual punishments inflicted. 11. That jurors ought to be duly empanelled and returned, and jurors which pass upon men in trials for high treason ought to be freeholders. 12. That all grants and promises of fines and forfeitures of particular persons, before conviction, are illegal and void. 13. And that for redress of all grievances, and for the amending, strengthening, and preserving of the laws, parliaments ought to be held frequently."

It is added that the Lords and Commons "do claim, demand, and insist upon all and singular the premises as their undoubted rights and liberties; and that no declarations, judgments, doings, or proceedings, to the prejudice of the people in any of the said premises, ought in anywise to be drawn hereafter into consequence or example."

The act also recognises their Majesties William III. and Mary as King and Queen of England, France, and Ireland, and the dominions thereunto belonging; and declares that the crown and royal dignity of the said kingdoms and dominions shall be held by their said majesties during their lives and the life of the survivor of them; that the sole and full exercise of the regal power shall be only in and executed by King William, in the names of himself and her majesty, during their joint lives; and that after their decease the crown shall descend to the heirs of the body of the queen, and, in default of such issue, to the Princess Anne of Denmark and the heirs of her body, and, failing her issue, to the heirs of the body of the king.

The Declaration of Rights is understood to have been principally the composition of Lord (then Mr.) Somers, who was a member of the first, and chairman of the second, of two committees, on whose reports it was founded. The original draught of the Bill of Rights was also probably the production of his pen. In the latter especially, there is very apparent a desire to preserve in the new arrangement as much as possible of the principle of hereditary succession to the crown. The legislature, for instance, in strong terms expresses its thankfulness that God had mercifully preserved King William and Queen Mary to reign over them "upon the throne of their ancestors;" and the new settlement is cautiously designated merely "a limitation of the crown." Mr. Burke has, from these expressions, contended (in his 'Reflections on the Revolution in France') that the notion of the English people having at the Revolution asserted a right to elect their kings is altogether unfounded. "I never desire," he adds, in repudiation of the opposite opinion as held by one class of persons professing Whig principles, "to be thought a better Whig than Lord Somers, or to understand the principles of the Revolution better than those by whom it was brought about, or to read in the Declaration of Rights any mysteries unknown to those whose penetrating style has engraved in our ordinances and in our hearts the words and spirit of that immortal law."

It has been sometimes stated, even so lately as by Lord Macaulay in his 'History' (as is pointed out by Mr. Knight in his 'Popular History of England'), that this act "deprived the crown of the power of arbitrarily removing the judges;" but neither the act, nor the Declaration of Rights which preceded it, contains a word on the subject. It was effected, however, by the Act of Settlement (13 Wm. III. c. 2), in 1701. Equally erroneous has been the assigning of this measure to the 1 George III. c. 2, which has been even more generally done. This act merely provided that the judges should not be removeable on the accession of a new sovereign.

The Declaration and Bill of Rights may be compared with the Petition of Rights (drawn up by Sir Edward Coke), which was presented by parliament to Charles I. in 1628, and passed by him into a law. [PETITION OF RIGHT.]

BILL OF SALE, a deed or writing under seal, evidencing the sale of personal property. In general, the transfer of possession is the best evidence of ownership, but cases frequently occur in which it is necessary or desirable that the change of property should be attested by a formal instrument of transfer; and in all cases in which it is not intended that the sale shall be followed by delivery, such a solemnity is essential to the legal efficacy of the agreement. The occasions to which these instruments are commonly made applicable are sales of fixtures and furniture in a house, of the stock of a shop, of the goodwill of a business (which of course is not transferable by delivery), of an office, or the like. But their most important use is in the transfer of property in ships, which being held in shares cannot, in general, be delivered over on each change of part ownership. It seems to have been from ancient times the practice, as well in this country as in other commercial states, to attest the sale of ships by a written

document; and at the present day a bill of sale is necessary to the validity of all transfers of shares in British ships, whether by way of sale or of mortgage, and the instrument must be registered at the port where the ship is registered. (17 & 18 Vict. c. 104.) In general, bills of sale, being *ex vi termini* founded on valuable consideration, are available against the creditors of the seller. But by the operation of the Bankruptcy laws, goods remaining with the consent of the true owner in the order and disposition of the insolvent at the time of his bankruptcy, are deemed to be the property of the latter, and pass to his assignees to be distributed with the rest of his effects for the benefit of his creditors. In all cases, a bill of sale of *personal chattels* must be registered, within twenty-one days after the making thereof, in the judgment office of the Queen's Bench, otherwise it will, as against assignees in bankruptcy or insolvency, or creditors, be null and void. (17 & 18 Vict. c. 36.) Moreover, in all cases such a deed may be set aside on proof that it was a merely colourable and fraudulent expedient for defeating the claim of *bond fide* creditors, the courts of law being little disposed to favour assignments of this kind, made secretly and without the notoriety which attends the actual transfer of possession.

BILLON, in coinage, is a composition of precious and base metal, consisting of gold or silver alloyed with copper, in the mixture of which the copper predominates. The word came to us from the French. According to Boutteroue, in France, billon of gold was any gold beneath the standard of twenty-two carats fine; and billon of silver all below ten pennies fine. Boizard says that gold beneath the standard as far as twelve carats fine, and silver to six pennies fine, were properly base gold and base silver; but that it was the mixture under those quantities which made billon of gold and billon of silver, in consequence of copper being the prevailing metal. Black money, or billon, was struck in the mints of the English dominions in France, by command of the kings of England, for the use of their French subjects. Money of billon was common throughout France from about the year 1200. Hardies, authorised money of Edward the Black Prince, are also found of similar mixture. It was probably one consideration with Henry VIII. in coining base money, that it would circulate in France to his advantage. Henry VIII. and Queen Elizabeth both coined base money, approaching to billon, for the use of Ireland.

Nothing precisely corresponding to billon is now coined by any of the great European states; although in some the abasement, or alloy, of gold and silver coinage is carried to a much greater extent than in England.

BILLS OF MORTALITY, are returns of the deaths which occur within a particular district, specifying the numbers that died of each different disease, and showing, in decennial or smaller periods, the ages at which decease took place. When the accuracy of these returns can be depended upon, facts of great importance in their actual application to the business of life may be deduced from them. From the mortuary tables, commenced at Geneva in 1566, which have been continued until the present time, it is ascertained that at the Reformation one-half of the children born died within the sixth year; in the 17th century, not till within the twelfth year; and in the 18th century, not until within the twenty-seventh year. Tables of this description, extending over a long period, mark the progress of a country in wealth and happiness; and the share which political causes have had in producing the results which they indicate, is a subject worthy of the highest consideration of the statesman and politician. The Northampton Tables of Mortality, also the Carlisle Tables, and the Swedish Tables, have served as the chief basis on which annuities, life insurances, and other calculations relating to the duration of human life, have been founded. The London Bills were commenced after a great plague in 1593. The weekly bills were begun in 1603, after another visitation of still greater severity. Imperfect as these documents are, there does not exist a complete collection of them, not even in the British Museum. In London, the Bills of Mortality included the City of London, the City and Liberties of Westminster, the Borough of Southwark, and thirty-four out-parishes in Middlesex and Surrey, the whole containing a population of 1,178,374 in 1831; but they did not contain St. Luke's, Chelsea, population, 32,371; Kensington, 20,902; St. Mary-le-bone, 122,206; Paddington, 14,540; and St. Pancras, 103,548;—total, 293,567. In the year in which the census was taken (1831) the number of deaths published in the annual Bill of Mortality was 25,337, or 1 in 46, on a population, as above stated, of 1,178,374.

In 1837 this system, if system it could be called, was wholly abolished by the passing of the Registration Act of the 6 & 7 Will. IV. c. 86, by which returns of all the births, deaths, and marriages, in England and Wales were secured, and which was extended to Scotland in 1854, by the 17 & 18 Vict. c. 80. [REGISTRATION OF BIRTHS, DEATHS, AND MARRIAGES.]

BINARY COMPOUNDS. [NOMENCLATURE, CHEMICAL.]

BINARY THEORY. [SALTS.]

BINETHIDE OF TIN. [ORGANOMETALLIC BODIES.]

BINITROBENZOIC ACID. [BENZOIC ACID.]

BINITROBENZOLE, *Dinitrobenzole*. [BENZOLE.]

BINITRONAPHTHALIN, *Dinitronaphthalin*. [NAPHTHALIN.]

BINNACLE, an article used on board ship which contains the compass. It is placed next the steersman, and is often divided into compartments for containing an hour-glass and a lamp. In order that the compass may remain unaffected by any local cause, the binnacle is not

put together with nails or any iron work. The binnacle has of late become an object of great consideration, from its being made to contain arrangements of correcting magnets and soft iron, on principles so ably worked out by Professor Airy. [LOCAL ATTRACTION.] Bittacle, being an abbreviation of the French word *habitable*, a small habitation, was the name formerly given to this article, and it is so called in Johnson's 'Dictionary;' but it is now written binnacle.

BINOMIAL, in algebra, means an expression which contains two terms, such as

$$a+b \quad b-cx \quad a^2x-py.$$

Any expression may be considered and used as a binomial in any sense in which it may be said to contain two terms: thus,

$$a+b+cx-ex$$

when put in the form

$$(a+b)+(c-e)x$$

is a binomial, the terms of which are $a+b$ and $(c-e)x$.

BINOMIAL EQUATION. [EQUATION, BINOMIAL.]

BINOMIAL THEOREM, by far the most important theorem in common algebra, first announced by Newton, as will presently appear. It is frequently called on the Continent the *binome de Newton*, and is often said, but wrongly, to have been engraved on his tomb in Westminster Abbey. In explaining this theorem, we shall consider ourselves as writing for those who have already such a knowledge of algebra as will enable them easily to recognise the various expressions of which we make use.

The binomial theorem, coupled with those preceding theorems from which it springs, is as follows:—

(1.) If a be denoted by a^1 , aa by a^2 , and aaa by a^3 , &c., then

$$a^m \times a^n = a^{m+n} \quad \frac{a^m}{a^n} = a^{m-n} \quad (m > n).$$

(2.) The equations in (1.) will hold good when the symbol a^0 is considered, provided that a^0 always signifies unity.

(3.) The equations in (1.) will hold good when negative exponents are employed, provided that

$$a^{-1} \text{ means } \frac{1}{a} \quad a^{-2} \text{ means } \frac{1}{a^2}, \text{ \&c.}$$

(4.) The equations in (1.) will hold good when fractional exponents are employed, provided that

$$\begin{aligned} a^{\frac{1}{2}} &\text{ means the square root of } a \\ a^{\frac{1}{3}} &\text{ „ „ cube root of } a \\ a^{\frac{1}{4}} &\text{ „ „ fourth root of } a, \text{ \&c.} \end{aligned}$$

and also that

$$\begin{aligned} a^{\frac{2}{3}} &\text{ means } (a^2)^{\frac{1}{3}} \text{ the cube root of } a^2 \\ a^{\frac{4}{7}} &\text{ „ } (a^4)^{\frac{1}{7}} \text{ the seventh root of } a^4 \\ a^{\frac{m}{n}} &\text{ „ } (a^m)^{\frac{1}{n}} \text{ the } n\text{th root of } a^m. \end{aligned}$$

(5.) *Binomial Theorem.* In all the preceding cases, that is, whether n be whole or fractional, positive or negative,

$$\begin{aligned} (1+x)^n &= 1 + nx + n \frac{n-1}{2} x^2 + n \frac{n-1}{2} \frac{n-2}{3} x^3 \\ &\quad + n \frac{n-1}{2} \frac{n-2}{3} \frac{n-3}{4} x^4 + \text{\&c.}, \end{aligned}$$

the preceding being a series of an infinite number of terms in all cases, except only where n is a positive whole number. The p th term of the preceding expression is

$$n \frac{n-1}{2} \frac{n-2}{3} \dots \frac{n-p+2}{p-1} x^{p-1},$$

which expresses any term after the second.

(6.) The preceding series is convergent, whatever may be the value of n , whenever x is less than 1. If x be greater than 1, it is always divergent; but the series remaining after any term may be expressed in a finite form, as follows: Let v_1, v_2, v_3 , &c., represent the several terms of the preceding series, then all the terms after the p th term are an algebraical development of a term of the form

$$v_{p+1} (1+\theta x)^{n-p},$$

where θ is a function of x , the arithmetical value of which is less than unity, so that

$$(1+x)^n = v_1 + v_2 + \dots + v_p + v_{p+1} (1+\theta x)^{n-p}$$

$$v_1 = 1 \quad v_2 = nx \quad v = n \frac{n-1}{2} x^2, \text{ \&c.}$$

The preceding theorem, though theoretically necessary to those who do not allow the use of divergent series, is of no practical use in the determination of $(1+x)^n$, since the determination of θ itself is the more difficult problem of the two.

We shall now give the early history of this theorem, with some remarks upon its demonstration.

Before the time of Vieta, no materials for its expression were in the hands of algebraists. That writer first used general symbols of determinate number: and in his works we find the first rude cases of the binomial theorem, though only in the results of simple multiplications, and without the discovery of any law of connexion among the coefficients. For instance, in his 'Ad Logisticen speciosam Notæ priores,' we find the following:

"Sit latus unum A, alterum B. Dico A quad.-quadratum + A cubo in B quater, + A quadrato in B quadrato sexies, + A in B cubum quater, + B quad.-quadrato, æquari A + B quad.-quadrato." This we should now express thus:

$$(a+b)^4 = a^4 + 4a^3b + 6a^2b^2 + 4ab^3 + b^4.$$

The coefficients of the binomial theorem, in the case of a whole exponent, had long been derived from the method employed in what Pascal called the Arithmetical Triangle, and Briggs the *abacus* $\pi\acute{\alpha}\chi\eta\sigma\tau\omicron\varsigma$. To trace the history of this method would here lead us too far [FIGURATE NUMBERS]; it must suffice to say that Lucas Pacioli, Stifel, Stevinus, Vieta, and others, all had in their possession something from which, if we did not know that such simple relations were difficult to discover, we should say a little attention would have enabled them to find the first glimpse of the binomial theorem, which, as we shall proceed to state, occurred to Briggs.

The *abacus* of the last-mentioned writer above alluded to is as follows (we have only reversed right and left):

1	1	1	1	1 &c.
2	3	4	5	6 &c.
3	6	10	15	21 &c.
4	10	20	35	56 &c.
5	15	35	70	126 &c.
&c.	&c.	&c.	&c.	&c.

In which each number is formed by adding that on the left to that immediately above. On which ('Trigonometria Britannica,' 1633, preface, p. 22) Briggs remarks, that by ascending obliquely, the coefficients of the several powers are obtained; for instance, that 4, 6, 4 are the coefficients of the fourth power, 5, 10, 10, 5, of the fifth power, and so on. Briggs therefore knew the dependence of these coefficients on the preceding columns of figurate numbers, but not the algebraical expression for the n th of each class.

The next step was made by Wallis, in his 'Arithmetica Infinitorum,' published in 1655. One of the great objects of this work was the determination of the areas of a class of curves, involving a problem amounting to the determination of

$$\int (1-x^2)^m dx \text{ from } x=0 \text{ to } x=1$$

where m is a whole number. In this he deduces the algebraical expressions for any figurate number, but not in the form in which Newton afterwards gave. For example, he prefers

$$\frac{l^3 + 3l^2 + 2l}{6} \text{ to } l \frac{l+1}{2} \frac{l+2}{3},$$

though it appears he knew the latter form. But he confined himself almost entirely to the *definite* integral, and did not exhibit his results in the form of algebraic series. His work is broken into propositions, after the manner of the ancients, and the simple form in which Newton afterwards enunciated his results does not appear (that we can find) in his work. It was as follows, using the notation already adopted, or rather Newton expressed it as follows, and in the method of expression is the happy simplification which led him to the binomial theorem. In the first column is the expression of the ordinate of the curve in question; in the second, the area included between the abscissa, the ordinates at its extremities, and the intercepted curve.

$(1 \pm x^2)^0$	x
$(1 \pm x^2)^1$	$x \pm \frac{1}{3}x^3$
$(1 \pm x^2)^2$	$x \pm \frac{2}{5}x^3 + \frac{1}{7}x^5$
&c.	&c.

Wallis had suggested that the method of determining the area of the circle depended upon finding a mean term between 1 and $\frac{2}{3}$ in the series, $1, \frac{2}{3}, \frac{8}{15}$, made by taking the lower sign in the preceding set, and making $x=1$ (he was considering the total areas). For the ordinate of the circle being $\sqrt{1-x^2}$, the exponent of which is $\frac{1}{2}$, the mean between 0 and 1, the question reduced itself to this: If 0, 1, 2, &c., operated upon according to a certain law, give the results $1, \frac{2}{3}, \frac{8}{15}$, &c., what will $\frac{1}{2}$ give when operated upon according to the same law? This interpolation he attempted, and obtained his well known and remarkable expression for the ratio of the circular area to the square on its diameter. But he could not succeed in the interpolation, and as he informs us himself in his 'Algebra,' afterwards published in 1685, "he gave it over as a thing not feasible," one difficulty being that he could not imagine a series with more than one term and less than two, which it seemed to him the interpolated series must have. And here the question rested till it was taken up by Newton. The latter, in a celebrated letter to Oldenburg, dated October 24, 1676, speaking of some developments then newly discovered by Leibnitz, gives the binomial theorem. We shall give his own words (that is, translated

from the Latin): "In the beginning of my mathematical studies, when I happened to meet with the works of our celebrated Wallis, in considering the series, by the intercalation of which he exhibits the area of the circle and hyperbola." . . . He then goes on to describe what we have already alluded to . . . "for interpolating between these I remarked that in all the first term was x , and the second terms were in arithmetical progression . . . that the two first terms of the series to be intercalated should be

$$x - \frac{1}{3}x^3 \quad x + \frac{1}{3}x^3, \text{ \&c.}$$

For the remaining intercalations I reflected that the denominators were in arithmetical progression; so that only the numerical coefficients of the numerators remained to be investigated. But these, in the alternate areas, were the figures of the powers of the number eleven, namely $11^0, 11^1, 11^2, 11^3, 11^4$; that is, in the first 1; in the second, 1, 1; in the third, 1, 2, 1; in the fourth, 1, 3, 3, 1; in the fifth, 1, 4, 6, 4, 1. I inquired, therefore, in what manner all the remaining figures could be found from the first two; and I found that if the first figure be called m , all the rest could be found by the continual multiplication of the terms of the formula

$$\frac{m-0}{1} \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \times, \text{ \&c.}$$

"This rule, therefore, I applied to the interpolation of the series. And since in the circle the second term is $\frac{1}{3} \times \frac{1}{3}x^3$, I made $m = \frac{1}{3}$. . . whence I found the required area of the circular segment to be

$$x - \frac{1}{3}x^3 - \frac{1}{5}x^5 - \frac{1}{7}x^7 - \frac{1}{9}x^9 - \text{ \&c.}$$

"This was my first introduction to such meditations, and it would have gone out of my memory, had I not cast my eyes on some of my notes a few weeks since. But when I had learned these things, I presently considered that the terms themselves $(1-x^2)^0, (1-x^2)^1, (1-x^2)^2$, &c., might be interpolated in the same manner as the areas generated from them, and that nothing more was necessary except the omission of the denominators 1, 3, 5, 7, &c. in the terms expressing the areas: that is, that the coefficients of the quantity to be intercalated $(1-x^2)^{\frac{1}{2}}$, or $(1-x^2)^{\frac{3}{2}}$, or generally $(1-x^2)^{\frac{m}{2}}$ would arise from continual multiplication of the terms of the series,

$$m \times \frac{m-1}{2} \times \frac{m-2}{3} \times \frac{m-3}{4} \text{ \&c.}"$$

Newton then proceeds to relate that he proved these operations by actual multiplication, and afterwards by applying the common rule for the extraction of roots, which gave the same results. He then states that he knew the common logarithmic series by the same method, and that being then much pleased with such investigations, he continued them until the appearance of Mercator's 'Logarithmotechnia'; when, suspecting that Mercator had made the same discoveries (which however was not the case) before he (Newton) was of an age to write, he began to care little about prosecuting his researches.

It must be noticed that Newton had previously given the theorem itself in a former letter to Oldenburg, dated June 13, 1676, with more copious examples; the statement of it is as follows: "The extraction of roots is much shortened by this theorem.

$$(P+PQ)^{\frac{m}{n}} = P^{\frac{m}{n}} + \frac{m}{n} A Q + \frac{m-m}{2n} B Q^2 + \text{ \&c.}$$

where A means the first term itself, B the second term," &c.

It must therefore be noticed, and similar things are common in the history of discovery, that several of those theorems which are now among the simple consequences of the binomial theorem, were in fact discovered before it. Thus Mercator and James Gregory had already used the logarithmic series, and Newton's discovery itself was not a consequence of any attempt at the general development of $(1+x)^n$, but of the series for $\int (1-x^2)^n dx$, which was (between certain limits) implied in the discoveries of Wallis.

Newton gave no other demonstration of his theorem except the verification by multiplication or actual extraction. The theorem of Stirling (commonly called after Maclaurin) and that of Taylor, being the general theorems of which the binomial is a particular case, soon diverted the attention of mathematicians. James Bernoulli first demonstrated the case of whole and positive powers by the application of the theory of combinations, in his treatise 'De Arte Conjectandi,' published after his death in 1713. Maclaurin, in his fluxions, published in 1742, gave, as we consider, the first general demonstration: for though he employs fluxions, yet he had not, as he himself notices (page 607), "made use of this theorem in demonstrating the rules in the direct method of fluxions." In later times, when the avidity with which the results of modern analysis were sought began so far to subside as to allow mathematicians to look at and discuss the grounds on which the several principles were established, a host of demonstrations appeared, each of which met with objectors: for it is a

property of all the fundamental theorems of every branch of mathematics to be incapable of establishment in a manner in which all shall agree, though the theorems themselves are held indisputable. Among these demonstrations are those of James Bernoulli, Maclaurin, Landen, Epinus, Stewart, Euler, Lagrange, L'Huilier, Manning, Woodhouse, Hutton, Bonnycastle, Knight, Robertson, Creswell, Swinburne, and Tylecote. We shall not discuss the various objections, because they apply as much to the general doctrine of infinite series as to the binomial theorem in particular; and we must refer the reader to TAYLOR'S THEOREM. We shall however allude to the principal objections after we have given what appears to us a sufficient proof of the theorem, or rather after we have indicated the steps of such a proof.

Definition.—By $(1+x)^{\frac{m}{n}}$ we mean (m and n being whole numbers) a quantity which, multiplied $n-1$ times by itself, gives $(1+x)^m$; and by the expansion of $(1+x)^{\frac{m}{n}}$, we mean an algebraical series of powers of x (positive or negative, whole or fractional) which has all the algebraical properties of $(1+x)^{\frac{m}{n}}$, and which, when it is convergent, has $(1+x)^{\frac{m}{n}}$ for its arithmetical limit or sum.

Theorem 1.—The well-known proof of the expansion of $(1+x)^m$, where m is a positive whole number, giving

$$\begin{aligned}(1+x)^2 &= 1+2x+x^2 \\ (1+x)^3 &= 1+3x+3x^2+x^3 \text{ \&c.}\end{aligned}$$

This theorem is not absolutely necessary, as we shall see.

Theorem 2.—If there be any function of a , namely ϕa , which satisfies the condition

$$\phi(a) \times \phi(b) = \phi(a+b),$$

then $\phi(a)$ must be c , where c is any quantity independent of a .

For the condition gives

$$\begin{aligned}\phi(a) \times \phi(b+c) &= \phi(a+b+c) \\ \text{or } \phi(a) \times \phi(b) \times \phi(c) &= \phi(a+b+c) \text{ \&c.}\end{aligned}$$

which leads (supposing b, c , &c., to be severally equal to a) to the equations

$$(\phi a)^n = \phi(na) \quad (\phi a')^m = \phi(ma'), \text{ \&c.}$$

where n and m are any whole numbers, and a, a' , &c., any quantities whatsoever. Let us suppose $ma' = na$, which gives

$$\begin{aligned}\phi(ma') &= \phi(na) \text{ or } (\phi a')^m = (\phi a)^n \\ \text{or } \phi a' &= (\phi a)^{\frac{n}{m}} \text{ or } \phi\left(\frac{n}{m} a\right) = (\phi a)^{\frac{n}{m}}.\end{aligned}$$

Again, the supposed universality of the first equation gives

$$\phi(0) \times \phi(a) = \phi(a+0) = \phi(a)$$

or $\phi(0) = 1$: and also

$$\phi(a) \times \phi(-a) = \phi(a-a) = 1$$

$$\begin{aligned}\text{whence } \phi(-a) &= \frac{1}{\phi a} \quad \phi(-na) = \frac{1}{\phi(na)} \\ &= \frac{1}{(\phi a)^n} = (\phi a)^{-n}\end{aligned}$$

so that the equation $\phi(na) = (\phi a)^n$ is true for all values of n : if a be $= 1$, this gives $\phi n = \{\phi(1)\}^n$, and $\phi(1)$ is not a function of the general symbol n : let $\phi(1) = c$, which gives the theorem asserted.

This theorem is the fundamental part of Euler's proof of the binomial theorem.

Theorem 3.—If the values of a and b may be made as near to equality as we please, then the limit of the fraction

$$\frac{a^n - b^n}{a - b} \text{ is } n a^{n-1}$$

In the case where n is a whole number, this is evident by the well-known theorem

$$\begin{aligned}(a^2 - b^2) \div (a - b) &= a + b \\ (a^3 - b^3) \div (a - b) &= a^2 + ab + b^2 \\ (a^4 - b^4) \div (a - b) &= a^3 + a^2b + ab^2 + b^3 \text{ \&c.}\end{aligned}$$

Let n be a positive fraction, for instance, $\frac{2}{3}$; and let $a = \alpha^3$, $b = \beta^3$. Then $a^{\frac{2}{3}} = \alpha^2$, $b^{\frac{2}{3}} = \beta^2$ and

$$\frac{a^{\frac{2}{3}} - b^{\frac{2}{3}}}{a - b} = \frac{\alpha^2 - \beta^2}{\alpha^3 - \beta^3} = \frac{\alpha + \beta}{\alpha^2 + \alpha\beta + \beta^2}$$

the limit of which, when a approaches to b , is $2\alpha \div 3\alpha^2$ or $\frac{2}{3}\alpha^{-1}$ or $\frac{2}{3}\alpha^{-\frac{1}{3}}$ or $\frac{2}{3}\alpha^{\frac{2}{3}-1}$. In the same way any other case may be proved.

Now let n be negative, say it is $-t$, where t is positive. Then

$$\frac{a^n - b^n}{a - b} = \frac{a^{-t} - b^{-t}}{a - b} = -\frac{1}{a^t b^t} \frac{a^t - b^t}{a - b}$$

of which the limit, by the two preceding cases (t being positive), is

$$-a^{-2t} \times t a^{t-1} \text{ or } -t a^{-t-1} \text{ or } n a^{n-1}.$$

Theorem 4.—If $(1+x)^n$ admit of being expanded in a series of whole powers of x , then that series must be

$$1 + nx + n \frac{n-1}{2} x^2 + n \frac{n-1}{2} \frac{n-2}{3} x^3 + \dots$$

Let

$$\begin{aligned}(1+x)^n &= t_0 + t_1 x + t_2 x^2 + \text{\&c.} \\ (1+y)^n &= t_0 + t_1 y + t_2 y^2 + \text{\&c.} \\ \frac{(1+x)^n - (1+y)^n}{(1+x) - (1+y)} &= t_1 + t_2 \frac{x^2 - y^2}{x - y} + \text{\&c.}\end{aligned}$$

which two sides being always equal, the limits to which they approach, as x approaches to y , are equal; or

$$n(1+x)^{n-1} = t_1 + 2t_2 x + 3t_3 x^2 + \text{\&c.}$$

Multiply both sides by $1+x$, which gives

$$n(1+x)^n = t_1 + (2t_2 + t_1)x + (3t_3 + 2t_2)x^2 + \text{\&c.}$$

but by the original assumption

$$n(1+x)^n = nt_0 + nt_1 x + nt_2 x^2 + \text{\&c.} \text{ and}$$

therefore

$$\begin{aligned}t_1 &= nt_0 \\ 2t_2 + t_1 &= nt_1 \text{ or } t_2 = n \frac{n-1}{2} t_0 \\ 3t_3 + 2t_2 &= nt_2 \text{ or } t_3 = n \frac{n-1}{2} \frac{n-2}{3} t_0 \\ &\text{\&c.} \quad \text{\&c.}\end{aligned}$$

But, making $x=0$ in the original series, we find $t_0 = (1)^n = 1$. Whence follows the theorem.

Theorem 5.—The value of $(1+x)^n$ is in all cases the series above investigated.

Consider that series as a function of n . Or let

$$\phi(n) = 1 + nx + n \frac{n-1}{2} x^2 + \text{\&c.}$$

$$\phi(m) = 1 + mx + m \frac{m-1}{2} x^2 + \text{\&c.}$$

Actual multiplication will be found to give

$$\phi n \times \phi m = 1 + (m+n)x + \frac{m+n-1}{2} x^2 + \text{\&c.}$$

or $\phi n \times \phi m = \phi(n+m)$.

Or we may dispense with this multiplication by remembering that since ϕn is $(1+x)^n$ and ϕm is $(1+x)^m$, when n and m are whole numbers, we must have, in that case (Theorem 1.),

$$\phi n \times \phi m = (1+x)^{m+n} = \phi(m+n)$$

but the result of a multiplication does not depend upon the values of the letters; if therefore ϕm and ϕn give $\phi(m+n)$ when m and n are any whole numbers, they give the same result when m and n are fractional or negative. But we do not yet know that ϕm in the latter cases represents $(1+x)^m$. But by theorem (2.) it follows from $\phi m \times \phi n = \phi(m+n)$ that ϕn is $\{\phi(1)\}^n$, or

$$\left(1 + 1x + 1 \frac{1-1}{2} x^2 + \text{\&c.}\right)^n \text{ or } (1+x)^n.$$

The greater part of the preceding proof is a concession to the analytical taste of the age, which requires that synthetical demonstration shall not appear in algebra. The theorem is demonstrated rigorously so soon as it shall be proved that from $\phi m \times \phi n = \phi(m+n)$, it necessarily follows that ϕm is $\{\phi(1)\}^m$, and that the series above-mentioned satisfies the equation just named. And in reading the objections which have been made against the various proofs of the binomial theorem, the student must bear in mind that there is one class of objections against the the actual logic of the processes, and another arising out of the conventions already alluded to. Against the demonstration of Euler, which consists in theorems 2. and 5. of the preceding, one says that it is "tentative" (synthetical would have been the proper word); another that it is not "algebraical," meaning analytical, and assuming that algebra must be analysis. To all of which we should reply by another question—Is it logical deduction from self-evident premises?

The last attempt to produce an unanswerable demonstration of the binomial theorem was made by Messrs. Swinburne and Tylecote of St. John's College, Cambridge (Deighton, 1827). The details are much too complicated to describe, but the general result is the expansion of $(1+x)^n$ to any number of terms, with a finite expression for the remainder. This expression is however so complicated and long, that it can be of no use, except as proved that the remainder can be assigned by the ordinary operations of algebra. The proof is certainly, if the details be correct, of a logical character, but it is far above the student. The remarks on other demonstrations in the preface, though dissenting entirely from many of them, we should recommend to the attention of the advanced student, as an exercise in the consideration of objections. At the same time we may recommend the remarks in Woodhouse's 'Analytical Calculations.'

BINOXIDE OF PHENYL. [OXYPHENIC ACID.]

BINOXIDE OF PROTEIN. [PROTEIN.]

BIOGRAPHY, a modern term, and one indeed of only recent introduction, formed from the Greek *bios* (*bios*), 'life,' and *γραφη* (*graphie*), 'writing;' and therefore signifying literally 'life-writing.' It is that department of literature which treats of the actions and fortunes of individuals. Biography is commonly distinguished from history by the latter term being confined to the narration of the actions and fortunes, not of individuals, but of the large communities of men called states and nations; but properly biography is only a branch of history. Thus Thomas Stanley, in the preface to his 'History of Philosophy,' observes, "There are two kinds of history; one represents general affairs of state, the other gives account of particular persons, whose lives have rendered them eminent." At the time when this was written (the middle of the 17th century) the word biography, we believe, had not been invented. Stanley adds, "Homer hath given an essay of each; of the first in his *Iliads*, a relation of a war between different nations; of the second in his *Odysseys*, confined to the person of Ulysses."

Owing to this their natural connection, history and biography are frequently combined in the same work. Indeed it is scarcely possible to write any history of a nation, which shall not consist, in a great part, of narratives or notices of the acts of individuals. The life of every eminent political character, and of every person who has been conspicuously engaged in the conduct of any department of public affairs, makes a portion of the history of his country. But besides such occasional threads of biography as are interwoven in almost every historical composition, a more formal intermixture, or association in the same work, of biographical details with national history, has sometimes been attempted. Thus, for example, to his 'History of the Age of Louis XIV.' Voltaire has added a biographical appendix of the more celebrated writers, painters, musicians, sculptors, and other artists who lived in France during that period. So, in the very useful 'Synopsis of Universal History,' written in German by J. H. Zopf, of which there is an enlarged and otherwise improved translation into French (5 vols. 12mo. 1810), an account of the most eminent writers of every century is regularly added to the abridgment of political events. In most recent histories, the progress of literature is in a similar manner traced alongside of that of national affairs, in distinct chapters, containing accounts of the lives and writings of men of letters. There is indeed scarcely any other way than this of incorporating the history of literature with the history of political transactions; and it will therefore be more or less resorted to whenever the former subject is thought of sufficient importance to be included in the writer's scheme.

But biography has sometimes been intermixed with history on a more comprehensive principle. We have an example of this in one of the divisions of the 'Encyclopædia Metropolitana,' which is described in the plan of the work as containing "Biography chronologically arranged, interspersed with introductory chapters of National History, Political Geography, and Chronology." Here the history would appear to be subordinate to the biography. In the 'General Introduction' to the Encyclopædia, which was written by Mr. Coleridge, though much altered both by interpolation and otherwise after it left his hands, it is said, "Biography and history tend to the same points of general instruction, in two ways: the one exhibiting human principles and passions acting upon a large scale; the other showing them as they move in a smaller circle, but enabling us to trace the orbit which they describe with greater precision. . . . Assuredly the great use of history is to acquaint us with the nature of man. This end is best answered by the most faithful portrait; but biography is a collection of portraits. At the same time there must be some mode of grouping and connecting the individuals, who are themselves the great landmarks in the map of human nature. It has therefore occurred to us that the most effectual mode of attaining the chief objects of historical knowledge will be to present history in the form of biography chronologically arranged. . . . Thus will the far greater portion of history be conveyed, not only in its most interesting, but in its most philosophical and real form; while the remaining facts will be interwoven in the preliminary and connecting chapters." No work on this plan however making any pretension to completeness, or at all satisfactory in execution, has yet appeared: and the inconveniences attending it are too obvious to be overlooked.

Some of the most ancient literary compositions in existence are works of biography, or of mixed biography and history. In the historical books of the Old Testament the narrative of public events is everywhere intermixed with the lives of individuals—patriarchs, lawgivers, captains, high priests, judges, kings, and other rulers or eminent characters. In some cases the composition is purely biographical, as the Book of Ruth.

Of professed biographical works, by far the greatest that has come down to us from the Greeks, is the 'Parallel Lives' of Plutarch, written in the 2nd century of our æra. This work comprehends distinguished characters in all the departments both of military and civil life. Another collection of very small value is that of the 'Lives of Eminent Greek and Roman Commanders,' written by Cornelius Nepos, in the reign of Augustus. There is also the work entitled 'The Lives of the Twelve Cæsars' by Suetonius, which, however, is necessarily in some degree of an historical character. It is a very indigested composition, to whatever class it may be considered as belonging. Suetonius

likewise wrote a book of lives of celebrated grammarians, of which some fragments have been preserved. "They who writ of philosophy," says Stanley, "exceeded the rest far in number, of whom to give a particular account will be unnecessary, because their works are not extant, and therefore we shall only name them: Aetius, Anaxilides, Antigonius, Antisthenes, Aristocles, Aristomenus, Callimachus, Clitomachus, Diocles, Diogenes Laërtius, Eunapius, Heraclides, Hermippus, Hesychius, Hippobotus, Ion, Idomeneus, Nicander, Nicias, Panætius, Porrius, Plutarch, Sotion, and Theodorus. Of almost all these (which is much to be deplored) there remain not any footsteps; the only author in this kind for the more ancient philosophers is Diogenes Laërtius; for the later, Eunapius. And to make the misfortune the greater, that which Laërtius gives us is so far short of what he might have done, that there is much more to be found of the same persons dispersed amongst other authors." Diogenes lived in the beginning of the 3rd century. At the end of the 2d and beginning of the 3rd century we have Flavius Philostratus, who wrote a collection of biographies in two books, entitled 'Lives of the Sophists.' Of single biographical sketches the ancients have also left us several, most of which seem to have been originally prefixed to editions of the works of the persons to whom they relate. Thus we have a Life of Homer attributed to Herodotus; and another of Plato, by Olympiodorus of Alexandria. Of all such single lives perhaps the most curious is that of Apollonius of Tyana, written in Greek by the Philostratus above-mentioned. An earlier life of Apollonius, which is now lost, is said to have been written by his disciple and contemporary Damis.

Since the revival of letters numerous biographical works have appeared in every language of Europe. Many of these have been accounts of the lives of single individuals, published either separately, or (in the case of authors) along with the works of the persons to whom they relate. In some cases the writer of such a life has aimed at making his work present a history, political, ecclesiastical, literary, or general, of the age to which its subject belonged. As answering a similar end, though written apparently with a less particular regard to the same object, may be mentioned one of the most amusing, and in some respects one of the most perfect, of all biographical works, Boswell's Life of Johnson. Others of these single lives are called autobiographies, or narratives which individuals have written of their own lives. A collection of the most celebrated autobiographies, which it is evident must in general have certain peculiarities strikingly distinguishing them from common biographical accounts, was published a few years ago in London by Messrs. Hunt and Clarke, in 34 vols. 18mo.

Cæsar's Commentaries of the Gallic and Civil Wars may be quoted as examples of autobiographical works in ancient literature. Another example is afforded by the lost history of his own times, also entitled Commentaries, written by the Greek General Aratus, which Polybius mentions. [ARATUS, BIOG. DIV.]

The collections of Lives that have appeared in modern times have also been very numerous. Thus we have the various martyrologies, or accounts of the lives and deaths of the early Christian martyrs, by Ruinart (fol. Amsterdam, 1713), by Assemani (2 vols. fol. Rom. 1748), &c. There is also the great work of the Flemish Jesuits, Bollandus, Henschenius, &c., entitled 'Acta Sanctorum Omnium,' which was begun to be published at Antwerp in 1643, and is of the enormous extent of fifty-three volumes folio. The 16 volumes quarto of Tillemont's work, entitled 'Mémoires pour servir à l'Histoire Ecclésiastique de vi. premières siècles de l'Eglise,' (Paris, 1693, &c.) is also in the main a work of ecclesiastical biography. There are also the Lives of the Fathers, by St. Jerome, and by many succeeding writers; the Lives of the Popes by Anastasius, commonly called the 'Bibliothecary,' and by others in later times; the Histories of the various monastic orders, which are all in the greater part biographical; and such works as John Fox's 'Book of Martyrs,' &c. As examples of collections of lives of the members of different artificial orders of persons among ourselves, may be noticed such works as Ashmole's 'History of the Order of the Garter,' the various Peerages and Baronetages; Wilson's 'Biographical Index to the House of Commons,' (Lond. 1806); Ward's 'Lives of the Professors of Gresham College,' Wood's 'Athenæ Oxonienses,' which is an account of writers educated at Oxford, &c.

The lives of eminent statesmen, military commanders, admirals, navigators, travellers, highwaymen, and various other descriptions of persons, either in all countries, or in some one country, have frequently formed the subjects of distinct works. Boccaccio wrote a work in Latin, first published at Ulm in 1473, in folio, entitled 'Opus de Claris Hominibus et Mulieribus,' and in subsequent editions, 'De Casibus Virorum et Feminarum Illustrium,' being a history of unfortunate princes and princesses, and other persons of eminence. A translation of this work into English verse, from a very paraphrastic French version executed by Laurent de Premierfait, was composed by John Lydgate, who lived in the reign of Henry VI., under the title of 'The Tragedies gathered by John Bochas of all such princes as fell from their estates through the mutability of fortune since the creation of Adam until his time.' The poem is commonly known by the title of Lydgate's 'Fall of Princes.' Somewhat similar to the design of this work, and indeed confessedly borrowed from it, is that of the celebrated collection of poems, first published in quarto, in 1559, with the title of 'A Mirror for Magistrates, wherein may be seen, by example of others,

with how grievous Plagues Vices are punished, and how frail and unstable worldly Prosperity is found, even of those whom Fortune seemeth most highly to favour.' But the narratives in the 'Mirror for Magistrates,' are all selected from English History, from which, as the editor in his dedication complains, Boccaccio had omitted to take any of his examples. A new edition of the 'Mirror for Magistrates,' which ranks so high in our old poetry, on account of the two admirable pieces which it contains,—the Induction and the Complaint of Henry Duke of Buckingham, by Thomas Sackville, the first Lord Buckhurst and first Earl of Dorset—appeared in 2 vols. 4to. in 1815, under the superintendence of the late Mr. Haslewood. Many biographical works have appeared, containing exclusively the lives of females. A collection of some of the earliest of these was published in a folio volume at Paris in 1521, under the title of 'Opera Diversorum aliquot Scriptorum de Claris Mulieribus ex editione Jo. Ravisii Textoris.' Two of the books of Brantome's *Mémoires* are occupied with gallant women (Dames Gallantes), and one with illustrious women. Menage wrote a work entitled 'Historia Mulierum Philosophorum.' There is a little book in French, called 'La Galerie des Femmes Fortes,' by Pierre le Moyne, an edition of which, adorned with handsomely executed portraits, was published by the Elzevirs at Leyden, in 1660. There was published at Paris, in 3 vols. 12mo., in 1779, a 'Dictionnaire Historique Portatif des Femmes Célèbres.' Bayle (*Dictionnaire*, Art. 'Urraca,' note E.) complains that writers of lives usually select only persons of distinguished merit, and that of women especially who have been the disgrace of their sex and their country no biographical account as far as he knew had appeared. "Yet," he continues, "it is a subject which it would be well worth some writer's pains to handle. It might be treated after the fashion of Plutarch; I mean that as that famous author has chosen the most illustrious Romans, and the most illustrious Greeks, in order to draw parallels between them, the queens and princesses of different nations might in like manner be compared together."

The most numerous class of biographical works is that of collections of literary biography. Of these many of the most important are mentioned under the article BIBLIOGRAPHY. Among others which are not noticed there, we may mention such works as the 'Pulcher Tractatus de Vita Philosophorum,' by Walter Burley (the Venerable Doctor, as he was called), 4to. Colon. 1472, a very rare volume; the 'History of Philosophy, containing the Lives, Opinions, Actions, and Discourses of the Philosophers of every sect,' by Thomas Stanley, which appeared in four successive volumes in 1655, 1656, 1660, and 1662, and has since been translated into Latin, as well as several times reprinted in English; the 'Historia Critica Philosophiæ' of Brucker, 5 vols. 4to. Leipzig, 1741-4, and second edition, 6 vols. 4to. 1767; the 'Theatrum Virorum Eruditione Clarorum' of Paul Freher, 2 vols. fol. Noriberg, 1688; the 'Vitæ Virorum Eruditorum' of Melchior Adam, 2 vols. fol. Francf. ad Moen. 1705; the 'Mémoires pour servir à l'Histoire des Hommes Illustres dans la République des Lettres,' of J. P. Niceron, 42 vols. 12mo. Paris, 1729-45; the 'Lives and Characters of the English Dramatic Poets,' by Gerard Langbaine, 8vo. Lon. 1698; the 'Biographia Dramatica' of D. E. Baker, first published in 1764, the best edition of which is that published by the late Mr. Isaac Reed, in 2 vols. 8vo. in 1782; the 'Lives of the English Poets,' by Dr. Johnson, &c.; the 'Biographia Britannica Literaria,' Anglo-Saxon and Anglo-Norman periods, by Thomas Wright, published by the Royal Society of Literature, 8vo. 1842. Almost more numerous perhaps have been the collections of biographies of artists; as examples of which may be mentioned Vasari's 'Lives of the most eminent Painters, Sculptors, and Architects,' first published at Florence in 2 vols. 4to. in 1550, and repeatedly since with many additions; Sandrart's 'L'Academia Todesca; Teutsche Academie der edlen Bau- Bild- und Mahlerey Künste,' 4 vols. fol., Nürnberg, 1675-79, better known by the Latin translation, 'Academia Nobilissimæ Artis Pictoriæ,' Nürnberg. 1783; 'True Effegies of the most eminent Painters and other famous Artists that have flourished in Europe,' sm. folio, Lond. 1694 (with 120 portraits, originally published at Antwerp in 1649); Pascoli's 'Vite de Pittori, Scultori, ed Architetti Moderni,' Rome, 1736; the Dictionary of Artists of Pelegrino Antonio Orlandi, first published at Bologna in 4to. in 1719, under the title of 'Abecedario Pittorico'; J. B. Descamp's 'La Vie des Peintres Flamands, Allemands, et Hollandois,' 4 vols. 8vo. Par. 1753-64; D'Argenville's 'Abrégé de la Vie des plus fameux Peintres,' 4 vols. 8vo. Paris, 1762; Hüber, 'Notices générales des Graveurs divisés par Nations, et des Peintres rangés par Écoles,' &c. 8vo. Dresden, 1787; Lanzi's, 'Storia Pittorica,' of which the first part appeared in 1790, the last in 1796, but which he afterwards considerably extended in subsequent editions; Horace Walpole's 'Anecdotes of Painting in England and Catalogue of Engravers,' forming in all 4 vols. 4to. 1761-1771; Pilkington's 'Dictionary of Painters,' 4to. 1770, and 2 vols. 8vo. 1829; 'Lives of the most eminent British Painters, Sculptors, and Architects,' by Allan Cunningham, 6 vols. 12mo. 1829-33; the great work of Nagler, 'Neues allgemeines Künstler-Lexicon, oder Nachrichten von dem Leben und den Werken der Maler, Bildhauer, Baumeister, Kupferstecher, Formschneider, Lithographen, Zeichner, Medailleure, Elfenbeinarbeiter, &c.,' 22 vols. 8vo. München, 1835-51; Stirling's 'Annals of the Artists of Spain,' 3 vols. 8vo. 1848; and many other works of a similar description.

Of the principal collections of exclusively British biography an account is given in the preface to the first edition of the 'Biographia

Britannica.' The writer mentions the 'Catalogus Scriptorum Ecclesiæ,' composed by John Boston, a Benedictine monk of St. Edmundsbury, in the reign of Henry IV. (which was never published, and of which there are but few manuscript copies extant); the 'Commentarii de Scriptoribus Britannicis' of John Leland, prepared in the reign of Henry VIII., but first published at Oxford in 2 vols. 8vo. in 1709; John Bale's 'Scriptorum Illustrium Majoris Britanniae Catalogus,' the first part of which was published at Ipswich, and the same year at Wesel, in 4to. in 1549: the first complete edition appeared at Basel in the same form in 1557; the treatise entitled 'De Academiis et Illustribus Angliæ Scriptoribus,' by John Pits, the first volume of which (the only one that was ever given to the world) was published in 4to. at Paris in 1619; the 'Historia Ecclesiastica Gentis Scotorum' of Thomas Dempster, 4to. Bonon. 1627, and of which a new edition was printed a few years ago by the Bannatyne Club of Edinburgh, a work of no authority, or rather indeed a mere romance; Sir James Ware's work, 'De Scriptoribus Hiberniæ,' 4to. Dublin, 1639, also translated into English, with a continuation, in the editions of his collected works published in 1739 and in 1764; and Fuller's 'Worthies of England,' folio, 1662. The first edition of the 'Biographia Britannica,' or the Lives of the most eminent persons who have flourished in Great Britain and Ireland from the earliest ages to the present times, was begun to be published at London in 1747, and was completed in 5 vols. folio, in 1766. Most of the best articles in this work were written by Dr. John Campbell, the author of the 'Political Survey of Great Britain'; among the other writers were the Rev. Thomas Broughton, William Oldys, and Philip Morant, author of the 'History of Essex.' A new and much extended edition of the 'Biographia Britannica' was begun in 1778 by the late Dr. Andrew Kippis, but was not carried farther than the fifth volume (folio), which brings down the alphabetical list of names only to the letter F. This edition, besides a great mass of new matter collected by the laborious editor, is enriched by communications from Lord Hailes, Lord Hardwicke (the author of the 'Athenian Letters'); Dr. Percy, Bishop of Dromore; Dr. Douglas, Bishop of Salisbury; Sir William Blackstone, Isaac Reed, and several other eminent literary persons of that time. Perhaps the most important body of British biography that has issued from the press, since the publication of the 'Biographia Britannica,' is the work of the late Mr. John Nichols, entitled 'Literary Anecdotes of the Eighteenth Century,' 9 vols. 8vo. Lond. 1812-16, with the supplement entitled 'Illustrations of the Literature of the Eighteenth Century,' 5 vols. 8vo. 1817-28. Another work of considerable value in this department is that entitled 'Portraits of Illustrious Personages of Great Britain, with Biographical and Historical Memoirs' by Edmund Lodge, Esq., 12 vols. 8vo. Lon. 1823-35. This last-mentioned work is on a somewhat similar plan to the 'Heads of Illustrious Persons of Great Britain,' engraved by Houbraken and Vertue, with memoirs by Dr. Birch, which appeared in 2 vols. fol. in 1752. Mr. Grainger's 'Biographical History of England,' originally appeared in 2 vols. 4to. in 1769, and was afterwards extended by the author to four 8vo volumes. A continuation of Mr. Grainger's work, in 3 vols. 8vo., by the Rev. Mark Noble, appeared in 1806. The 'Gallery of Portraits, with Memoirs,' completed in 1837, in 7 vols. imp. 8vo., contains a selection of 129 of the most eminent individuals of all countries, of whom the memoirs have been written with great care and ability.

Of general biographical dictionaries, the 'Dictionarium Historico-Geographico-Poeticum,' of Charles Stephens, published in 4to. at Geneva, in 1566, two years after the death of the author, may probably be regarded as the earliest; but this work, as its title indicates, contained many others besides biographical articles. The same remark applies to the 'Dictionarium Historicum, Geographicum, Poeticum, Gentium, Hominum, &c.,' of our countryman, Nicholas Lloyd, which appeared in folio, first at Oxford in 1670, and again, greatly enlarged, at London in 1686. A much more extended work, of a similar description, is the 'Lexicon Universale Historico-Geographico-Chronologico-Poetico-Philologicum,' of Jo. Jac. Hofman; the first edition of which, in 2 vols. folio, was printed at Bâle in 1677. A Supplement, or 'Continuation,' as it is called, of the same extent, followed in 1683; and, finally, the two publications were incorporated in a new edition published at Leyden in 4 vols. folio, in 1698. Hofman's work may be considered as the origin of our modern encyclopædias. Our exclusively biographical dictionaries may be regarded as having been rather suggested by another work which appeared about the same time, 'Le Grand Dictionnaire Historique et Critique,' of Louis Moreri. This work, the first edition of which appeared in 1 vol. folio, in 1673, although its contents were also very miscellaneous, was still of a more decidedly biographical character than that of Hofman. Of Moreri's Dictionary there have been about twenty editions in French, the last of which appeared at Paris in 1759, in 10 vols. folio. Upon Moreri's Dictionary was founded the 'Great Historical, Geographical, Genealogical, and Poetical Dictionary,' printed at London in 1694: the second edition of which, 'revised, corrected, and enlarged to the year 1688, by Jeremy Collier, A.M.,' appeared in 2 vols. folio, in 1701. To these a third volume was added in 1705, containing a Supplement by Collier, and, in a separate alphabet, 'a Continuation from the year 1688 to this time, by another hand.' The whole was afterwards republished, with additions, in 4 vols. folio, in 1727. Meanwhile the immortal 'Dictionnaire Historique et Critique' of Bayle, originally

undertaken with the view of supplying the deficiencies and correcting the errors of Moreri, but which, in the course of preparation, soon assumed the form and character of an independent work, appeared in 2 vols. folio, at Rotterdam, in 1697. A second edition, enlarged to 3 vols., followed in 1702; and a third in 1722, after the death of the author, at Geneva, in 4 vols., the last being a supplementary volume consisting of additional articles which he had left ready for the press. The best of the old editions of Bayle is the fourth, published at Rotterdam in 4 vols. folio, in 1720, under the superintendence of Prosper Marchant, and often called the 'Regent edition,' from being dedicated to the Regent of France, Philip, Duke of Orleans; but an edition in 17 vols. 8vo., recently appeared at Paris, which, from the annotations it contains in correction of the original text, is now the most complete and valuable. Bayle's Dictionary, though it contains only a selection of names, is almost exclusively biographical. A very indifferent translation of it into English was published soon after the appearance of the original; but one much better executed was produced some years after by Peter Des Maizeaux, in 5 vols. folio, London, 1734-7. To Bayle's Dictionary should be added the Supplement to it by Chauffepié, published in 4 vols. folio, Amsterdam, 1750. The valuable 'Dictionary of Greek and Roman Biography and Mythology,' edited by Dr. W. Smith, 3 vols. 8vo, 1844-49, may also be mentioned here.

The first 'English General (exclusively) Biographical Dictionary' appeared in 1762, in 11 vols. 8vo. "It is understood" (says the writer of an article 'On Universal Biographies' in the 'London Magazine,' No. XII. third series) "to have been projected and principally written by the Rev. Dr. Heathcote, who, assisted by the late Mr. Nichols, brought out a second edition of the work in 12 vols. in 1784. A third edition in 15 vols. appeared in 1798, under the superintendence of Mr. Tooke, the author of the 'History of Russia.' It is the last edition of this work which goes by the name of Chalmers's 'Biographical Dictionary,' which, having been begun to be published in 1812, was completed in 1817, in 32 vols. 8vo. Chalmers's 'Dictionary' is merely a hurried and tasteless compilation, and without any pretensions to be regarded as an authority. It is a better book, however, than the 'General Biographical Dictionary' of Drs. Aikin and Enfield, in 10 vols. 4to., begun in 1799, and finished in 1815. Of smaller English works of this description there have been several, but none of much merit: the best perhaps is that by the late Mr. John Gorton, published in 2 vols. 8vo. in 1828. The most exhaustive attempt at a 'Biographical Dictionary' was made by the Society for the Diffusion of Useful Knowledge in 1842, but it was discontinued in 1844, when only the letter A was completed. That portion occupied seven 8vo. volumes, each volume containing considerably more than one of the 'Biographie Universelle.' In this the names of the contributors of the articles were given. Another 'Biographical Dictionary' is that of H. J. Rose, in 12 vols. 8vo., of which a second edition was published in 1848. The 'Biographical Division of the English Cyclopædia' is more than equal to any of the foregoing in extent, and has the advantage over them of containing memoirs of living personages.

Of foreign biographical works the most remarkable was the great French work, the 'Biographie Universelle,' begun in 1810, and completed in 52 vols. 8vo. in 1828. To every article in this work the name of the writer is affixed; and the list of contributors, who are in all considerably above 300 in number, comprises the names of Biot, Delambre, Lacroix, Malte-Brun, Walckenaer, Sylvestre de Sacy, Sismondi, De Barante, Guizot, Cuvier, Victor Cousin, Chateaubriand, Benjamin Constant, Laplace, Madame de Stael, Delille, and many other of the then most eminent living French writers. This work has been reprinted with additions. A new general biographical dictionary begun in 1852, is now (1859) in course of publication, under the title of 'Nouvelle Biographie Générale,' and is a work of considerable merit. In French there are also the 'Biographie des Hommes Vivantes,' in 5 vols. 8vo.; and the 'Biographie Nouvelle des Contemporains,' in 20 vols., neither of which is of any great authority. A very remarkable and important oriental biographical and bibliographical dictionary is the 'Lexicon Encyclopædicum et Bibliographicum' of Haji Khalfa, in 7 vols. 4to, Leipzig, 1835-59. It is in Arabic and Latin, and has been edited by Professor G. Flügel at the cost of the Oriental Translation Fund of the Royal Asiatic Society, and is stated in the society's report for 1859, to have cost the society nearly 4000*l.*, and Prof. Flügel nearly twenty-five years of labour.

In Germany, the various editions of the 'Conversations Lexikon,' contain a large body of biography, on the whole executed with great care and correctness.

BIQUADRATIC, an algebraic term, meaning of the fourth degree, or which contains the fourth power of any letter. Thus, to find the value of x in

$$x^4 + 3x^2 = x + 100$$

is the solution of a biquadratic equation.

The term means "twice as high as a quadratic." [QUADRATIC.] Among the older algebraists, the fourth power was also denoted by the terms *quadrato-quadratum*, *plano-planum*, *suesolidum*, *zenzizensic* (corruption of an Arabic word), &c. The word *biquadratic* wore out of use, and it became customary to say "of the fourth degree" instead. It is now proposed to say *quartic* instead of *biquadratic*, and to call an

expression of some definite algebraical degree a *quantic*. We think the proposal a very good one.

BIRCH; ECONOMICAL USES. The birch is extremely valuable among our forest trees, from the variety of materials which it furnishes to the manufacturing arts. The timber, without possessing any one quality in an eminent degree, possesses many qualities in moderate extent. It is employed in France for the felloes of wheels, and in Russia for the construction of small rustic carriages. On many parts of the Continent it is used for divers articles of furniture, cooperage, and turnery, and for sabots or wooden shoes. The Highlanders of Scotland use birch for so many purposes that they are said to "make everything of it:" they frequently build their houses of it; make their chairs, tables, dishes, and spoons of it; construct their mills of it; make their carts, ploughs, barrows, gates, and fences of it; and even manufacture ropes of it. The above uses apply to the *white* birch. The *black* or *canoe* birch is also of great value; it flourishes in North America, and is there applied to numerous purposes. Some specimens of this timber are so beautifully grained that they are cut into veneers and used in cabinet work. The wood of the *tall* or *American* birch is used in the United States and Nova Scotia for yokes of cattle and frames of sledges, for hoops of casks, for articles of furniture, and for many other purposes. The wood of the *pliant* birch has a fine and close grain, and a considerable degree of strength, and takes a brilliant polish. It is used in the United States for tables, bedsteads, arm-chairs, sofas, coach-panels, shoe-lasts, and a great variety of purposes.

The *bark* of all the species of birch is of considerable value, especially in cold northern countries, where it is applied to a great variety of uses. It is very durable, and little acted on by air or water. In some countries it is used as a coping for walls and a covering for roofs. The bark of large trees is cut by the Laplanders into pieces large enough to form capes or short cloaks. It is also employed for boots, shoes, baskets, boxes, mats, cordage, harness, and thread. In Kamtschatka the inner bark is dried and ground, and mixed with oatmeal to form an article of food; and the same people eat the bark in small pieces with the roe of fish. It is much used for tanning leather; and a yellowish-brown dye which it yields is employed in some countries for dyeing woollens and rein-deer skins. The bark of the *canoe* birch is used in America for roof coverings, baskets, boxes, portfolios, paper, and inner soles of shoes; but it is more extensively employed in making the canoes of the *voyageurs* engaged in the fur trade of Canada: such a canoe, capable of accommodating four persons, will weigh no more than 40 lbs. Tents are also made of this bark. The bark of the *tall* birch is used in tanning; that of the *pliant* birch is stripped while in the green state by the Kamtschatkades, cut into narrow strips like vermicelli, and stewed with caviare.

The *branches* and young *shoots* are also of much value. They are made into hoops, brooms, faggot-ties, baskets, hurdles, cream-whisks, and similar articles, including the well-known rod of our old-fashioned schoolmasters. The Alpine mountaineers make torches of them. The Laplanders construct tents with birch branches covered with turf. In the Scottish Highlands the branches are employed as fuel in the distillation of whiskey, being found (or at least reputed) to impart a flavour to it which enhances its value. They are similarly employed for smoking hams and herrings. The young branches of the *dwarf* birch furnish beds and fuel to the Laplanders; and those of the *black* birch are employed in the United States for making hoops for rice-casks.

The *leaves*, *catkins*, and other green parts, have also their value. The leaves are eaten by goats and rabbits. A yellow colour is obtained from them, useful in painting and dyeing. The Finlanders use the dried leaves as tea. The buds and catkins afford a substitute for bees' wax. A bed stuffed with birch leaves is said to be useful to rheumatic persons by promoting perspiration. The leaves of the dwarf birch yield a peculiar kind of fungus, from which the substance called *moxa* or *amadou* is prepared, and which the Laplanders employ as a medicine in many painful diseases; and its seeds afford nourishment to the ptarmigan, or white partridge, a very important bird in Lapland.

The *sap* of the birch is made to yield beer, wine, spirit, vinegar, and sugar, according to the mode of treatment; the tree being tapped to allow the sap to flow or ooze out. Birch beer is made by fermenting the sap with yeast, hot water, and hops. Birch wine is made by boiling the sap with sugar or honey, and fermenting, clarifying, and flavouring in various ways. Birch spirit is made by distillation; birch vinegar, by allowing the acetous fermentation to supervene on the vinous; and birch sugar, by boiling and evaporating the sap.

To complete the catalogue of the use of the birch, we have to mention the *fuel*, the *ashes*, and the *oil*. The wood gives a bright and ardent flame, and is much employed for smelting iron in France, Russia, and Sweden; its charcoal burns a long time, and is in much demand for making gunpowder and black crayons. The ashes are rich in potash. An oil, much used in Russia, is obtained by burning birch bark in close receptacles.

BIRDLIME. When the middle bark of the holly is boiled for several hours with water, and then placed in a moist situation, as under moist earth, it enters into fermentation and becomes a viscid mass, from which birdlime may be prepared by bruising, washing, and kneading it to remove extraneous matters, and lastly leaving it again to ferment in earthen vessels. It may also be made from mistletoe and other plants. Birdlime owes its peculiar property to the presence

of a peculiar substance termed *viscin*, which may be obtained in a purer form by repeatedly digesting the berries of the mistletoe in ether, and finally expelling the ether at a gentle heat. Viscin is a white, tough, opaque, and very adhesive resin, which does not dry. It is soluble in ether, essential oils, and solution of potash, but insoluble in alcohol and dilute acids. Nitric acid converts it into oxalic acid and a solid fat. Macaire-Prinsep found it to consist of

Carbon		75.6
Hydrogen		9.2
Oxygen		15.2
		100.0

The same chemist believes birdlime to be a mixture of viscin, bassorin, and acetic acid, and that it does not exist in the plants from which it is procured, but is produced by fermentation. The viscosity and toughness of viscin are so great, that when small birds alight upon branches smeared with it, they cannot extricate themselves; hence the use of the impure substance by bird catchers.

BIRD'S-EYE VIEW, a mode of perspective representation, which may be divided into two kinds, *proper* and *improper*. The latter of these, the one most generally employed, differs from ordinary perspective delineation, in nothing else than in the horizon being taken much higher than usual: the horizontal line, and of course the point of sight, is either placed above the picture, or the level of the ground is supposed to be considerably below the base of the picture. The objects thus shown, whether buildings or landscape, or both combined, appear as they would do if viewed from some lofty station, from the summit of a building, from a terrace, tower, or any other eminence; but still the spectator is supposed to be looking in a straightforward direction, and the plane of the picture to be perpendicular to the natural horizon. Consequently, only distant objects can thus be shown, because, when looking in that direction, a person cannot possibly see objects immediately beneath him. He can do that only by looking down upon them; but in a picture there can be but one *instant* of view, nor can the point of sight be shifted at pleasure, by the eye being directed upwards or downwards, so as to alter the field of vision, and take different objects in succession. Whatever is shown in a picture must be supposed capable of being embraced by the eye at once; although in practice some slight degree of licence in this respect is occasionally allowable.

If it be desired to show the objects immediately below the spectator, so as to give a distant view of the tops of buildings so situated, and of parts that would otherwise be concealed from sight, recourse must be had to the first-mentioned mode, namely *proper bird's-eye* perspective. This is the reverse of that employed for ceiling-pieces, termed *di sotto in su*; for as there objects are fore-shortened as seen from below, so in the *bird's-eye* they are foreshortened, as if viewed from above. This species of *bird's-eye* might therefore with great propriety be distinguished by the name of *prone perspective*, or looking downwards; and the *di sotto in su*, by that of *supine perspective*, or looking upwards. In like manner as in ceiling perspectives, the plane of the picture becomes parallel to the natural horizon, instead of vertical, so does it in a *proper bird's-eye* view; with this difference, that in the former case the eye is beneath the picture and looking up to it; in the latter over it, and looking down upon it; at least, if not exactly horizontal, the plane of the picture must be more or less inclined, according as the eye is supposed to look down more directly or obliquely; because the *plane of projection* or picture must be assumed as perpendicular to the central ray from the eye. The relative position of objects to each other and to the picture, and of the picture to the eye, are the same in this as in ordinary perspective, the sole difference being that of the spectator's own situation. This will be apparent if we look into a hollow cube, or box, open on one side; it matters not whether it be open on one of the upright sides, or on the top. In either case the planes or sides perpendicular to the open side, and the one parallel to, or facing it, will have the same perspective appearance; only in the one case the plane facing the spectator will be vertical, in the other horizontal. In a picture or drawing this will depend entirely upon the artist—whether he chooses to represent the plane parallel to the picture as horizontal, that is the ground or floor, and the other planes perpendicular to the ground; or that parallel plane and two of the adjoining planes upright, and the other two horizontal. Again, were a hole bored through the ceiling of a lofty room, a person looking down through it would have a perfect or *proper bird's-eye* view, both of the apartment and its furniture. Hence, it is obvious that in such representation the floor would answer to what in the common mode of perspective would be the side or end of the room facing the spectator; also that the vertical lines of the sides of the room, of doors, windows, legs of chairs, &c., would vanish to some point in the line or plane passing through the eye, exactly as the horizontal lines would do if they were seen according to the usual position. For unless the lines, in this case intended to represent upright ones, were made to vanish, those planes or walls would not be foreshortened; and unless that were done they could not be viewed, but the whole would be reduced to a mere plan of the room; just as a common upright view would be reduced to a section or geometrical elevation, if the planes representing the other two walls with the ceiling and floor were not shown perspective or foreshortened. Yet, although such perspective or *bird's-eye* view would be correct in itself, it would seem too fanciful and unnatural, if not positively distorted, because

the objects would be shown under such very different circumstances from those according to which they are really seen; consequently, such kind of views would be quite unpictorial, and merely matters of curiosity. They might, indeed, occasionally be found useful as explanatory diagrams, or drawings, whenever it should be required to show the effect of an interior, as beheld from a lofty upper gallery, not viewed in a cross or straightforward direction, but by looking down into the lower area of the apartment. This *prone perspective* might also be applied for the purpose of giving a map-like, yet graphic view of a group of buildings and their locality. As a picture, however, such view would be extravagant, although as a picture-map it would have something to recommend it. Even the more usual kind of *bird's-eye* perspective, or view with a very elevated horizon, is by no means well calculated for picturesque effect, since it brings those parts of an edifice into view which are intended to be concealed, and otherwise greatly takes off from the architectural effect; causing the building so viewed to appear too much like a small model placed upon a table.

BIRDSMOUTH. [MOULDING.]

BIRTH. [INFANTICIDE.]

BISCUIT, in pottery, is a term used to denote porcelain as well as the commoner kinds of earthenware at a certain stage of the manufacturing process. To render them fit for most purposes, it is necessary that fictile wares should be covered with a vitreous glaze; and hence arises the necessity for subjecting them twice to the action of heat in furnaces. The first baking is necessary in order to preserve the shape and texture of the pieces; seeing that they would otherwise be altered in these respects through the absorption of the water from the glaze, which must be used in a fluid form. Neither would it be possible, for the same reason, to apply painting, or to transfer printed patterns to their surfaces in the green state—that is, previously to firing. It is after this first baking, and previous to the application of the glaze and of embellishments, that these wares receive the name of biscuit, which is given from the resemblance which they bear in colour and apparent texture to ship-bread. Strictly speaking, the name is a misnomer, seeing that these articles are not 'twice-baked' while in their biscuit state. The second firing is necessary in order to vitrify the glaze, and to bring out the metallic colours which are used for embellishing earthenwares.

The heat of the first oven must be at least equal to that employed for the vitrification of the glaze; because, as soon as that degree of heat to which earthenwares have been already subjected is passed, a further degree of shrinking occurs, which would occasion the glaze to crack and peel off—an effect which will not be produced by a repetition of the degree of heat that has been once applied. It is a property of clay to contract when subjected to any degree of heat greater than it has previously borne, but short of the point of fusion; and it is another property to continue at that same state of contraction at every other temperature which is not above the degree of heat to which it has once been subjected, and by which its actual state of contraction has been produced.

Earthenware in the state of biscuit is permeable to water, which however it imbibes without undergoing any alteration of texture. This quality fits it for being used in the cooling of fluids, which effect is produced through the rapid evaporation from the outer surface.

See further on this subject under POTTERY and PORCELAIN.

Many beautiful statuettes have been produced in the Staffordshire potteries during the last few years, from models by Bell and other sculptors, in materials more or less resembling biscuit-ware.

BISCUIT-MANUFACTURE. Biscuit (German, *Zweibach*; Dutch, *Scheepsbeschuit*; Danish, *Skibstvebak*; Swedish, *Skeppsbrod*; French, *Biscuit*; Italian, *Biscotto*, *Galletta*; Spanish, *Biscocho*, *Galleta*; Portuguese, *Biscoito*; Russ, *Bort*, *Ssucher*; Latin, *Panis Biscortus Nauticus*), a kind of bread made usually in the form of flat cakes. This form is given to biscuits to insure their being deprived of moisture in the baking, which circumstance is necessary for preserving them fit for use during the continuance of long voyages. The use of this kind of bread on land is indeed pretty general as a matter of luxury; but at sea, biscuits are an article of the first necessity, seeing that bread, in the more ordinary form in which it is used on shore, would speedily become mouldy and unfit for food.

The name biscuit ('twice-baked') is evidently derived from the nature of the processes to which this kind of bread was formerly subjected. The two bakings then used are no longer found necessary; but the name, although thus rendered inappropriate, has been continued.

We may confine our notice chiefly to that kind of biscuit which forms a principal part of the food of seamen, and which is for that reason usually known as ship-bread or biscuit. When intended for this use, biscuits are most commonly made of the meal of wheat from which only the coarsest bran has been separated. It is hardly possible to be too particular in the selection of meal for this purpose; since any damage to which it may have been subject, either before or after being ground, would prevent biscuits, however carefully made, from keeping sound for any length of time. The preparation of sea-biscuit is carried on as a substantive branch of business in almost every port of resort for vessels engaged in trading with distant countries.

The largest biscuit-manufactories are those maintained by government for supplying the navy. The scale upon which these are carried on is such as to make it of great importance to introduce into the process

every simplicity compatible with the goodness of the articles; and improvements have, with this view, been made from time to time to lessen the amount of labour in the establishments. The mode of conducting the operations, on what may be termed the hand-method, is as follows:—

Meal and water being mixed together in due proportion, the dough is placed upon a wooden platform. A wooden roller, or staff, has one end fixed by means of a staple and eye to the wall, so that the roller can be made to traverse the surface of the platform; and when the dough is placed upon it, the roller is used to knead it by indenting upon it lines radiating in a semicircle from the staple. To perform this kneading process, a man seats himself upon the overhanging end of the roller, and proceeds with a riding motion backwards and forwards through the semicircular range until the dough is sufficiently kneaded; it is a very uncouth process, in which muscular labour is wastefully applied. In this kneaded state the dough is cut by large knives into slices, which are subdivided into small lumps, each sufficient for making a biscuit. In moulding these small lumps, which is done by hand, the dough undergoes a further degree of kneading, and at length receives the form of the biscuit. The men who thus fashion the dough make two of these cakes at the same time, working with each hand independently of the other. When this part of the work is completed, the two pieces which have been simultaneously prepared are placed one on the other and handed over to another workman, by whom the two together are stamped with a toothed instrument, the use of which is to allow the equable dissipation of moisture through the holes from all parts of the biscuit during the baking. The biscuits are then separated by another workman, who places them on a particular spot of a small table standing close to the mouth of the oven, so that each biscuit can be taken up in its turn without the necessity of his looking for it, by the man who supplies the oven. The office performed by this man is that of throwing the biscuits in succession upon the peel, which is held by another man whose business is to arrange them in the oven. This peel is a flat thin board, a few inches square, which can, by means of a long handle, be slidden over the floor of the oven, so as to deposit and arrange the biscuits thereon. The greatest nicety is required on the part of the man who thus throws the biscuits on the peel, and he could not perform this evolution with the necessary degree of precision if he were at any time obliged to withdraw his eye from the peel in search of the biscuit. The oven is by these means supplied at the rate of seventy biscuits in one minute. The mouth of the oven is necessarily open during the time of its being charged; the heat is therefore greater at the beginning than at the end of that operation; and besides this, the biscuits first deposited are of course a longer time exposed to heat than the rest. To remedy the irregularity that might be thus occasioned, the pieces of dough are gradually and regularly made of smaller bulk, so that the effect of the cooler oven is equalised by the smallness of the biscuits. When sufficiently baked, the biscuits are placed in the warm atmosphere of rooms well-ventilated over the ovens, and remain there until perfectly dry. In this state it is found that one hundred and two pounds of biscuits are procured from one hundred and twelve pounds of meal.

Notwithstanding the perfection to which the hand-method has attained, the processes have of late years been still further perfected and facilitated by the introduction of machinery. In the Royal Dockyards, the dough is thoroughly mixed and rolled out into sheets about two yards long and one wide, which are stamped at one stroke into about sixty hexagonal biscuits of six to the pound,—in such a manner as to leave the sheet sufficiently coherent to be put into the oven as one piece, though when baked the biscuits are easily separated. The hexagonal shape has been substituted for the circular, because it effects a saving of time and material, and also of space in packing.

At the ship biscuit bakery of Mr. Harrison, at Liverpool, an apparatus has been constructed which exceeds in automatic completeness even that employed at the government establishments; for the made biscuits travel into the oven without the aid of any peel or other hand-worked tool. The flour and water are placed in a cylinder, mixed well together by revolving bars, kneaded by a large iron cylinder, and spread like a large sheet on an endless cloth. As this cloth travels along, a nicely adjusted piece of mechanism cuts the dough into the shape of six-sided biscuits, and stamps them. Passing along the endless cloth, the biscuits are received by a kind of gridiron, and enter the oven. This oven is 26 feet long; it is heated by hot water, and bakes the biscuits as they slowly travel through it. The mechanism was patented by Mr. Harrison, in 1849.

Mr. Deucale, an American inventor, has introduced an ingenious mode of baking biscuits. A brick oven, 12 feet long, 6 wide, and 4 high, stands in the middle of the bakehouse. The top has no opening whatever. The front has an opening near the ground, with a metal door, through which the fuel is introduced, and made to cover the entire area of the floor of the oven. About a foot above the furnace door is an opening, six or eight inches high, and the whole width of the oven; and a similar opening exists at the back. Near each opening is a wooden cylinder; around both cylinders a wire lattice-work is tightly coiled, so as to form an endless cloth stretching horizontally within and across the oven, over the fire. The biscuits, in the state of dough, being ranged in a row along the front edge of the wire-cloth, the baker turns a winch-handle, and winds them into the oven; this he

does row after row, until, by the time the first row has reached the back of the oven, the biscuits in that row are properly baked.

In another biscuit-baking apparatus, by Messrs. Barrett & Exhall, the flour is put into a receptacle, where it is speedily mixed into dough. This dough passes to a breaking machine, where it is kneaded until it becomes sufficiently tenacious to be passed between rollers for more thorough kneading. From these rollers it passes to other rollers, which reduce it to the required thickness. It then passes in a continuous sheet, by means of an endless web of canvas, to another machine, where it is cut, docked, crimped, and stamped. The biscuits are then divided from the waste dough, and conveyed to the oven. The waste dough is collected and passed through a shoot, to be re-kneaded, and made into biscuits.

It may here be remarked, in reference to navy biscuits, that an important national saving is effected by the use of machinery in the manufacture. Twenty years ago, it was calculated that the three government biscuit-bakeries at Deptford, Gosport, and Plymouth, could produce 7300 tons of biscuit in a year; that this quantity would cost 3200*l.* for labour, and wear and tear of machinery; that the wages and utensils on the old method would have cost 11,600*l.*; and that the nation thus saved 8400*l.* by employing machinery.

BISCUITS, MEAT. The meat-biscuits, which first became familiarly known in this country about the time of the Great Exhibition in 1851, are a kind of antiseptic or preserved food, introduced by Mr. Borden of America. As carried on at Galveston, in Texas (where excellent cattle abound at a very low price), the manufacture is so conducted as to concentrate the nutriment of the meat with flour, into a sort of biscuit. The biscuits are dry, inodorous, flat, brittle cakes, which will preserve their qualities for a (practically) unlimited period. No fat of beef is included; only the nutritive part of the lean. One pound of biscuit contains half a pound of wheaten flour combined with the nutriment from five pounds of beef. During the United States' war with Mexico these biscuits were taken as part of the army rations, packed in casks. When required for use, the biscuits are dissolved in water, boiled, and seasoned at pleasure, forming a soup about the consistency of sago. One ounce of biscuit will suffice for a pint of water. It can also be used as an ingredient in puddings and sauces. These meat-biscuits have not been brought much into use in England; yet Dr. Lindley, as a member of one of the juries of the Great Exhibition of 1851, spoke highly of them. He said: "I think I am justified in looking upon it as one of the most important substances which this Exhibition has brought to our knowledge. When we consider that by this method, in such places as Buenos Ayres, animals which are there of little or no value, instead of being destroyed, as they often are, for their bones, may be boiled down and mixed with the flour which all such countries produce, and so converted into a substance of such durability that it may be preserved with the greatest ease, and sent to distant countries: it seems as if a new means of subsistence was actually offered to us. Take the Argentine Republic, take Australia, and consider what they do with their meat there in times of drought, when they cannot get rid of it while it is fresh; they may boil it down, and mix the essence with flour,—and we know they have the finest in the world—and so prepare a substance that can be preserved for times when food is not so plentiful, or sent to countries where it is always more difficult to procure food. Is not this a very great gain?"

Professor Owen, as one of the jurors at the Paris Exhibition in 1855, noticed a kind of meat-biscuit which had been recently introduced in France by M. Beurmann. According to the information obtained, these meat-biscuits are thus prepared. Quarters of beef, immersed in water sufficient to cover them, are subjected to a long and slow ebullition. The liquid, after the fat has been skimmed off, is evaporated to the consistence of syrup; it is then incorporated with fine wheaten flour, in quantity sufficient to give it a consistence capable of yielding to the rolling-pin. When rolled out to the thickness of an ordinary ship biscuit, the cake is pricked and cut into the angular form best adapted for stowage. The meat-biscuits are then baked in an oven, thoroughly dried, and packed for exportation. They can be eaten in the dry state, like ordinary biscuits; and this confers great value on them for the soldier when in the trench or on the march. But they afford a more sapid and comforting kind of subsistence if they are broken up in about twenty times their weight of water, and boiled for half an hour with salt, or other condiments; an excellent and most nutritious soup is thus readily obtained.

See further on the subject of preserved meats under **ANTISEPTICS**.

BISHOP, the name of that superior order of pastors or ministers in the Christian church who exercise superintendency over the ordinary pastors within a certain district, called their see or diocese, and to whom also belongs the performance of those higher duties of Christian pastors, ordination, consecration (or dedication to religious purposes) of persons or places, and finally, excommunication.

The word itself is corrupted Greek. *Ἐπίσκοπος* (*episcopos*) became *episcopus* when the Latins adopted it. They introduced it among the Saxons, with whom, by losing something both at the beginning and the end, it became *piscop*, or, as written in Anglo-Saxon characters, *Byrceop*. This is the modern *bishop*, in which it is probable that the change in the orthography (though small) is greater than in the enunciation. Other modern languages retain in like manner the Greek term slightly

modified according to the peculiar genius of each, as the Italian *vescovo*; Spanish, *obispo*; and French *évêque*; as well as the German, *bischof*; Dutch, *bisschop*; and Swedish, *biskop*.

The word *episcopus* literally signifies "an inspector or superintendent;" and the etymological sense expresses even now much of the actual sense of the word. The peculiar character of the bishop's office might be expressed in one word—superintendency. The bishop is the overseer, overlooker, superintendent in the Christian Church, and an exalted station is allotted to him, corresponding to the important duties which belong to his office. It was not, however, a term which was invented purposely to describe the new officer which Christianity introduced into the social system. The term existed before, both among the Greeks and Latins, to designate certain civil officers to whom belonged some species of superintendency. (See Harpocrat. or Suidas in voc. *ἐπίσκοπος*.) Cicero ('ad Att.' lib. vii. ep. 11) speaks of himself as appointed an *ἐπίσκοπος* in Campana.

It has long been a great question in the Christian Church what kind of superintendency it was that originally belonged to the bishop. This question, as to whether it was originally a superintendency of pastors or of people, may be briefly stated thus:—Those who maintain that it was a superintendency of pastors challenge for bishops that they are an order of ministers in the Christian Church distinct from the order of presbyters, and standing in the same high relation to them that the apostles did to the ordinary ministers in the church; that, in short, they are the successors and representatives of the apostles, and receive at their consecration certain spiritual graces by devolution and transmission from them, which belong not to the common presbyters. This is the view taken of the original institution and character of the bishop in the Roman Catholic Church, in the English Protestant Church, and we believe in all churches which are framed on an episcopal constitution. Episcopacy is thus regarded as of divine institution, inasmuch as it is the appointment of Jesus Christ and the apostles, acting in affairs of the Church under a divine direction. There are, on the other hand, many persons who contend that the superintendency of the bishop was originally in no respect different from the superintendency exercised by presbyters as pastors of particular churches. They maintain that, if the question is referred to scripture, we there find that bishop and presbyter are used indifferently to indicate the same persons or class of persons, and that there is no trace in the scripture of two distinct orders of pastors; and that if the reference is made to Christian antiquity, we find no trace of such a distinction till about 200 years after the time of the apostles. The account which they give of the rise of the distinction which afterwards existed between bishops and mere presbyters is briefly this:

When, in the ecclesiastical writers of the first three centuries, we read of the bishops, as of Antioch, Ephesus, Carthage, Rome, and the like, we are to understand the presbyters who were the pastors of the Christian churches in those cities. While the Christians were few in each city, one pastor would be sufficient to discharge every pastoral duty among them; but when the number increased, or when the pastor became enfeebled, assistance would be required by him, and thus other presbyters would be introduced into the city and church of the pastor, forming a kind of council around him. Again, to account for the origin of dioceses or rural districts which were under the superintendency of the pastors, it was argued that it was the cities which first received Christianity, and that the people in the country places remained for the most part heathens or pagans (so called from *pagus*, a country village) after the cities were Christianised; but that nevertheless efforts were constantly being made to introduce Christian truth into the villages around the chief cities; and that whenever favourable opportunities were presented, the chief pastor of the city encouraged the erection of a church, and appointed some presbyter either to reside constantly in or near to it, or to visit it when his services were required, though still residing in the city, and there assisting the chief pastor in his ministrations. The extent of country which thus formed a diocese of the chief pastor would depend, it is supposed, on the civil distributions of the period; that is, the dioceses of the bishops of Smyrna, or any other ancient city, would be the country of which the inhabitants were accustomed to look to the city for the administration of justice, or in general to regard it as the seat of that temporal authority to which they were immediately subject.

All this is represented as having gone on without any infringement on the rights of the chief pastor, of whom there was a regular series. Lists of them are preserved in many of the more ancient churches, ascending, on what may be regarded sufficient historical testimony, and with few breaks in the continuity, even into the second and first centuries. Bishops are however found in churches for which this high antiquity cannot be claimed. In these cases they are supposed to be either in countries which did not fully receive Christianity in the very earliest times, or that the bishops or chief pastors delegated a portion of that superior authority which they possessed over the other presbyters to the presbyter settled in one of the churches which was originally subordinate. This is supposed to have been the origin of the distinction among the chief pastors of bishops and archbishops, there being still a slight reservation of superintendency and authority in the original over the newly created chief pastors.

If this view of the origin of the episcopal character and office be correct, it will follow that originally there was no essential difference

between the bishop and the presbyter, and also that the duties which belong to the pastor of a Christian congregation were performed by the bishop. But when the increase of the number of Christians rendered assistants necessary, and this became a permanent institution, then the chief pastor would divest himself of those simpler and easier duties, which occasioned nevertheless a great consumption of time, as a matter at once of choice and of necessity. Having to think and to consult for other congregations beside that which was peculiarly his own, and to attend generally to schemes for the protection or extension of Christianity, he would have little time remaining for catechising, preaching, baptising, or other ordinary duties; and especially when it was added that he had to attend councils, and even was called to assist and advise the temporal governors in the civil and ordinary affairs of state. When Christianity, instead of being persecuted, was countenanced and encouraged by the temporal authorities, it was soon perceived that the bishop would be a very important auxiliary to the temporal authorities; while in ages when few besides ecclesiastical persons had any share of learning, or what we call mental cultivation, it is manifest that the high offices of state, for the performance of the duties of which much discernment and much information were required, must necessarily be filled by ecclesiastics, who might be expected, as we know to have been the case, to unite spiritual pre-eminence with their high political offices. The Lord High Chancellor of England was always an ecclesiastic, and generally a bishop, to the time of Sir Thomas More, in the reign of Henry VIII.

The functions which belong to the bishop are in all countries nearly the same. We shall speak of them as they exist in the English Church. 1. Confirmation, when children on the threshold of maturity ratify or confirm the engagement entered into by their sponsors at baptism, which is done in the presence of a bishop, who may be understood in this ceremony to recognise or receive into the Christian Church the persons born within his diocese. 2. Ordination, or the appointment of persons deemed by him properly qualified, to the office of deacon in the church, and afterwards of presbyter or priest. 3. Consecration of presbyters when they are appointed to the office of bishop. 4. Dedication, or consecration of edifices erected for the performance of Christian services, or of ground set apart for religious purposes, as especially for the burial of the dead. 5. Institution or collation to vacant churches in his diocese. 6. Superintendence of the conduct of the several pastors in his diocese, in respect of morals, of residence, and of the frequency and proper performance of the public services of the church. And 7, Excommunication; and, in the case of ministers, deprivation and degradation.

These are the most material of the functions which have been retained by the Christian bishops, or, if we adopt the theory of apostolic succession, which have from the beginning been exercised by them. To these it remains to be added, that in England they are the medium of communication between the king and the people in respect of all affairs connected with religion; and that they are an important constituent part of that great council of the realm which is called parliament.

Whatever kind of moot, assembly, or council for the advice of the king there was in the earliest times of the English monarchy, the bishops were chief persons in it. The charters of the early Norman kings usually run in the form that they are granted by the assent and advice of the bishops as well as others; and when the ancient great council became moulded into the form of the modern parliament, the bishops were seated, as we now see them, in the Upper House. It is argued that they sit as barons [BARON], but the writ of summons runs to them as bishops of such a place, without any reference to the temporal baronies held by them. Down to the period of the Reformation they were far from being the only ecclesiastical persons who had seats among the hereditary nobility of the land, many abbots and priors having been summoned also, till the houses over which they presided were dissolved, and their office thus extinguished. Henry VIII. created at that time six new bishoprics, and gave the bishops placed in them seats in the same assembly. But before the nation had adjusted itself in its new position, there was a powerful party raised in the country, who maintained that a government of the church by bishops was not accordant to the primitive practice, and who sought to bring back the administration of ecclesiastical affairs to the state in which there was an equality among all ministers, and where the authority was vested in synods and assemblies. Churches upon this model had been formed at Geneva and in Scotland; and when this party became predominant in the parliament of 1642, a bill was passed for removing the bishops from their seats, to which the king gave a reluctant and forced assent. It was soon followed by an entire dissolution of the Episcopal Church. At the Restoration this Act was repealed, or declared invalid, and the English bishops have ever since had seats in the House of Lords, except that on the erection of Manchester into a see, it was enacted that the bishop last instituted shall not have a seat, and the bishop of Sodor and Man never had one. They form the Lords Spiritual, and constitute one of the three estates of the realm, the Lords Temporal and the Commons (the *tiers état*) being the other two. Out of this has arisen the question, now laid at rest, whether a bill has passed the House in a constitutional manner, if it has happened that no Lord Spiritual was present at any of its stages. When the House becomes a court for the trial of a peer

charged with a capital offence, the bishops withdraw, it being held unsuitable to the character of ministers of mercy and peace to intermeddle in affairs of blood.

For the execution of many of the duties belonging to their high function they have officers, as chancellors, judges, and officials, who hold courts in the bishop's name.

The election of bishops is supposed, by those who regard the order as not distinguished originally from the common presbyter, to have been in the people who constituted the Christian church in the city to which they were called; afterwards, when the number of Christians was greatly increased, and there were numerous assistant presbyters, in the presbyters and some of the laity conjointly. But after a time the presbyters only seem to have possessed the right, and the bishop was elected by them assembled in chapter. The nomination of such an important officer was, however, an object of great importance to the temporal sovereigns; and they so far interfered, that at length they virtually obtained the nomination. In England there is still the shadow of an election by the chapters in the cathedrals. When a bishop dies, the event is certified to the king by the chapter. The king writes to the chapter that they proceed to elect a successor. This letter is called the *congé d'élire*. The king, however, transmits to them at the same time the name of some person whom he expects them to elect. If within a short time they do not proceed to the election, the king may nominate by his own authority; if they elect any other than the person named in the king's writ, they incur the severe penalties of a *præmunire*, which includes forfeiture of goods, outlawry, and other evils. The bishop thus elected is confirmed in his new office under a royal commission, when he takes the oaths of allegiance, supremacy, canonical obedience, and against simony. He is next installed, and finally consecrated, which is performed by the archbishop or some other bishop named in a commission for the purpose, assisted by two other bishops. No person can be elected a bishop who is under thirty years of age.

The bishops in England have fixed salaries assigned to them, arising from their original endowments; but in some cases the estates are left in the hands of the bishops, who pay over the surplus, if any, to commissioners who have the management of others, paying the salary to the bishop. Their churches, which are called *cathedrals*, (from *cathedra*, a seat of dignity,) are noble and splendid edifices, the unimpeachable witnesses remaining among us of the wealth, the splendour, and the architectural skill of the ecclesiastics in England in the middle ages. The cathedral of the Bishop of London is the only modern edifice.

For other information on this subject, see ARCHBISHOP and ARCHDEACON.

Bishops in partibus.—This is an elliptical phrase, and is to be supplied with the word *Infidelium*. These are bishops who have no actual see, but who are consecrated as if they had, under the fiction that they are bishops in succession to those who were the actual bishops in cities where Christianity is extinct. Syria, Asia Minor, Greece, and the northern coast of Africa, present many of these extinct sees, some of them the most ancient and most interesting in the history of Christianity. When a Christian missionary is to be sent forth in the character of a bishop into a country imperfectly Christianised, and where the converts are not brought into any regular church order, the Pope does not consecrate the missionary as the bishop of that country in which his services are required, but as the bishop of one of the extinct sees, who is supposed to have left his diocese and to be travelling in those parts.

Suffragan Bishops.—In England, every bishop is, in certain views of his character and position, regarded as a suffragan of the archbishop in whose province he is. But the suffragan bishop is rather to be understood as a bishop *in partibus*, who was admitted by the English bishops before the Reformation to assist them in the performance of the duties of their office. When a bishop filled some high office of state, the assistance of a suffragan was almost essential, and was probably usually conceded by the Pope, to whom such matters belonged, when asked for. A catalogue of persons who have been suffragan bishops in England was made by Wharton, a great ecclesiastical antiquary, and is printed in an appendix to a Dissertation on bishops *in partibus*, published in 1784 by another distinguished church-antiquary, Dr. Samuel Pegge.

At the Reformation, provision was made for a body of suffragans. The Act 26 Henry VIII. c. 14, is expressly on this subject. It authorises each archbishop and bishop to name a suffragan, which is to be done in this manner: he is to present the names of two clerks to the king, one of whom the king is to select. He was no longer to be named from some extinct see, but from some town within the realm. Six-and-twenty places are named as the seats (nominally) of the suffragan bishops. They were these which follow:

Thetford,	Shaftesbury,	Bristol,	Cambridge,
Ipswich,	Molton,	Penrith,	Pereth,
Colchester,	Marlborough,	Bridgewater,	Berwick,
Dover,	Bedford,	Nottingham,	St. Germans,
Guildford,	Leicester,	Grantham,	and the
Southampton,	Gloucester,	Hull,	Isle of Wight.
Taunton,	Shrewsbury,	Huntingdon,	

This was before the establishment of the six new bishoprics.

Very few persons were nominated suffragan bishops under this Act. One, whose name was Robert Pursglove, who had been an abbot, and who was a friend to education, was suffragan bishop of Hull. He died in 1579, and lies interred in the church of Tideswell in Derbyshire, under a sumptuous tomb, on which is his effigy in the episcopal costume with a long rhyming inscription presenting an account, curious as being contemporary, of the places at which he received his education, and the ecclesiastical offices which in succession he filled.

Boy-bishop.—In the cathedral and other greater churches, it was usual on St. Nicholas-day to elect a child, usually one of the children of the choir, bishop, and to invest him with the robes and other insignia of the episcopal office; and he continued from that day (Dec. 6), to the feast of the Holy Innocents (Dec. 28), to practise a kind of mimicry of the ceremonies in which the bishop usually officiated, more for the amusement than to the edification of the people. The custom, strange as it was, existed in the churches on the continent as well as in England. It may be traced to a remote period. It was countenanced by the great ecclesiastics themselves, and in their foundation they sometimes even made provision for these ceremonies. This was the case with the archbishop of York in the reign of Henry VII., when he founded his college at Rotherham. Little can be said in favour of such exhibitions, but that they served to abate the dreariness of mid-winter. Much may be found collected on this subject in Ellis's edition of Brand's 'Popular Antiquities,' vol. i. The custom was finally suppressed by a proclamation of Henry VIII., in 1542.

BISHOPRIC is a term equivalent to diocese or see, denoting the whole district through which the bishop's superintendency extends. The final syllable is the Anglo-Saxon *rice*, *region*, which entered in like manner into the composition of one or two other words.

In England there are two archbishoprics and twenty-one bishoprics; in Wales four bishoprics; the Isle of Man forms also a bishopric, but the bishop has no seat in the English Parliament.

The basis of the present diocesan distribution of England was laid in the times of the Saxon Heptarchy. At the Conquest there were two archbishoprics and thirteen bishoprics, namely,

Canterbury,	Rochester,	Hereford,
York,	Salisbury,	Coventry and Lichfield,
London,	Bath and Wells,	Lincoln,
Winchester,	Exeter,	Norwich,
Chichester,	Worcester,	Durham.

The first innovation on this arrangement was made by King Henry I., who, to gratify the abbot of the ancient Saxon foundation at Ely, and to free him from the superintendence of the Bishop of Lincoln, in whose diocese he was, erected Ely into a bishopric, the church of the monastery being made the cathedral. He assigned to it as its diocese the county of Cambridge and some portion of Norfolk, perhaps as much as had formerly been comprehended within Mercia; for we have no better guide to the exact limits of the ancient Saxon kingdoms than the limitations of the ancient dioceses. This was effected in 1109.

The second was in 1133, near the end of the reign of Henry I., when the see of Carlisle was founded. The diocese consists of portions of the counties of Cumberland and Westmoreland, perhaps not before comprehended within any English diocese.

No other change took place till 1541, when King Henry VIII. erected six new bishoprics, facilities for doing so being afforded by the dissolution of the monastic establishments, which placed at the king's disposal large and splendid churches, and great estates, out of which to make a provision for the support of the bishops. These were: 1. Oxford, having for its diocese the county of Oxford, which had previously been included within the diocese of Lincoln. 2. Peterborough: this diocese was also taken out of that of Lincoln, and comprises the county of Northampton and the greater portion of Rutland. 3. Gloucester, having for its diocese the county of Gloucester, which had been previously in the diocese of Worcester. 4. Bristol, to which the city of Bristol, and the whole county of Dorset heretofore belonging to the diocese of Salisbury, were assigned. 5. Chester: to this a very large tract was assigned, namely, the county of Chester, heretofore part of the diocese of Lichfield and Coventry, and the whole county of Lancaster, part of Cumberland, and the archdeaconry of Richmond, all of which were before in the diocese of York. 6. Westminster, the county of Middlesex, which before had belonged to the diocese of London, being assigned to it as its diocese. This last bishopric however soon fell. In about nine years, Thirlby, the first and only bishop, was translated to the see of Norwich, and the county of Middlesex was restored to the diocese of London.

Since the year 1541 no change took place in the diocesan distribution of England until 1836, when, in order to lessen the great disproportion of the sees, the bishopric of Ripon was formed under the 6 & 7 Wm. IV. c. 77, consisting of detached parts of the dioceses of York and Chester, and the bishoprics of Gloucester and Bristol were united. Provision was also made for the creation of a bishopric of Manchester, for which room was to be made by uniting the sees of Bangor and St. Asaph. This part of the plan was subsequently abandoned, and in 1847 Manchester was erected into a bishopric, with a provision that no greater number of bishops should have a seat in the House of Lords, and, therefore, that the junior bishop (except of the bishoprics of London, Winchester or Durham) should be the one without a seat. The

diocese of Manchester consists of the whole county of Lancaster except the deanery of Furness and Cartmel. The Act 6 & 7 Wm. IV. made provision for uniting the see of Sodor and Man to that of Carlisle; but by 1 Vict. c. 30, its existence as a separate bishopric was preserved. The Act 6 & 7 Wm. IV. c. 77, not only remodelled dioceses, but provided for a more equal distribution of episcopal revenues, according to the following scale:—

ARCHBISHOPS.	
Canterbury	£15,000
York	10,000
BISHOPS.	
London	10,000
Durham	8,000
Winchester	7,000
Ely	5,500
St. Asaph and Bangor	5,200
Worcester	5,000
Bath and Wells	5,000

The other bishoprics are augmented by fixed contributions out of the revenues of the richer sees, so as to increase their average annual incomes to not less than 4000*l.* nor more than 5000*l.* The surplus revenues from the richer sees are paid into the hands of the Ecclesiastical Commissioners, and constitute what is called the Episcopal Fund; and every seven years, from Jan. 1, 1837, a new return is to be made by them of the revenues of all the bishoprics, and thereupon the scale of episcopal payments is to be revised, so as to preserve the scale fixed upon by the Act. Provision was also made in this Act for a more equal distribution of patronage among the several bishops, proportioned to the relative magnitude and importance of their respective dioceses.

The bishops of London, Durham, and Winchester rank next to the archbishops; the others rank according to priority of consecration.

While the Church of Scotland was episcopal in its constitution it had two archbishoprics, St. Andrew's and Glasgow, and eleven bishoprics, to which, as late as 1633, a twelfth was added, the bishopric of Edinburgh. In the other thirteen sees there is a long and pretty complete catalogue of bishops, running up to the 9th, 10th, 11th, or 12th centuries. The eleven ancient bishoprics were those of Aberdeen, Argyle, Brechin, Caithness, Dumblane, Dunkeld, Galloway, Moray, Orkney, Ross, and the Isles, or Sodor, a see which was formerly within the superintendency of the bishop of Man.

At the Revolution, the Presbyterian Church of Scotland was acknowledged as the national church; but there is still an episcopal church in Scotland, the members of which are there in the character of dissenters. The sees are Edinburgh, which is the seat of the primacy, Glasgow, Aberdeen, St. Andrew's, Brechin, Argyll, and Moray and Ross.

Before the changes in the Irish establishment, effected in 1833 by the 3 & 4 Wm. IV. c. 37, and the 4 & 5 Wm. IV. c. 90, there were four archbishoprics and eighteen bishoprics. Many of the latter had been formed by the union of sees, which had been effected at different epochs. At the time of the passing of the Act there were in the province of

Armagh.—Meath and Clonmacnoise, Clogher, Down and Connor, Kilmore, Dromore, Raphoe, and Derry.

Dublin.—Kildare, Ossory, and Ferns and Leighlin.

Cashel.—Limerick, Cork and Ross, Waterford and Lismore, Cloyne, and Killaloe and Kilfenora.

Tuam.—Elphin, Clonfert and Kilmacduagh, and Killala and Achonry.

By the Act mentioned, the archiepiscopal diocese of Tuam was united to that of Armagh, and that of Cashel to Dublin; but the two suppressed archbishoprics are now bishoprics. The diocese of Dromore is united to that of Down and Connor; that of Raphoe to Derry; Clogher to Armagh; Elphin to Kilmore; Killala and Achonry to Tuam and Ardagh; Clonfert and Kilmacduagh to Killaloe and Kilfenora; Kildare to Dublin and Glandelagh; Leighlin and Ferns to Ossory; Waterford and Lismore to Cashel and Emly; Cork and Ross to Cloyne. The diocese of Meath and Clonmacnoise, and that of Limerick, remained unaltered. The archbishoprics are reduced to two, and the bishoprics to ten. A large saving was effected by the amalgamation, and the surplus revenue arising from the suppressed sees is under the management of the Ecclesiastical Commissioners of Ireland, to be dispensed for ecclesiastical and educational purposes.

One archbishop and three bishops represent the Irish Church in the House of Lords. They are changed every session, according to a system of rotation by which all sit in turn.

The bishopric of Man is traced to Germanne, one of the companions of St. Patrick, in the 5th century; but there are many breaches in the series of bishops from that time to the present. Sodor, which is supposed to be a Danish term for the western Isles of Scotland, was under the same bishop till the reign of Richard II., when the Isle of Man having fallen under the English sovereignty, the Islands withdrew themselves, and had a bishop of their own. The nomination of the bishop was in the house of Stanley, earl of Derby, from whom it passed by an heiress to the Murrays, dukes of Athol, and has come by purchase to the crown. This bishopric was declared by an Act of 33 Henry VIII. to be in the province of York.

The Isle of Wight is part of the diocese of Winchester; and the isles of Jersey and Guernsey, with the small islands adjacent, are in the diocese of London.

The bishoprics in the British colonies have become numerous by the creation of new sees. The oldest colonial bishopric was that of Nova Scotia, created in 1787. In 1841 a meeting was held of the archbishops and bishops of England and Ireland at Lambeth Palace, when it was agreed to undertake the charge of funds then raising for the endowment of bishoprics in the colonies, and to become responsible for their application. In no case do they proceed without the concurrence of the government. They now consist of,—in North America, Nova Scotia, Quebec, Montreal, Toronto, Fredericton, Huron, Prince Rupert's Land, British Columbia, and Newfoundland; in Australasia, Sydney, Tasmania, Adelaide, Melbourne, Newcastle, Perth, Brisbane, New Zealand, Christchurch, Wellington, and Waiapu; in the West Indies, Jamaica, Barbadoes, Antigua, and Guiana in South America; in the East Indies, Calcutta, Bombay, Madras, Ceylon, and the islands of Mauritius and Labuan, and also Victoria (Hong Kong); in Africa, Cape Town, Natal, Graham's Town, and Sierra Leone; and in Europe, Gibraltar. British colonies or dependencies which are not within any diocese are considered to be under the pastoral care of the Bishop of London.

There are thirty-three Roman Catholic archbishops, bishops, coadjutor bishops, and vicars-apostolic in the British colonies. At Sydney, Quebec, and in Bengal, the Roman Catholic prelates are of the rank of archbishops.

In 1840, a very important Act (3 & 4 Vict. c. 86) was passed "for better enforcing Church Discipline," which repealed the old statute (1 Hen. VII. c. 4), under which bishops were enabled to proceed against their clergy, and sentence them to imprisonment. The new Act provides "that in every case of any clerk in holy orders of the United Church of England and Ireland who may be charged with any offence against the laws ecclesiastical, or concerning whom there may exist scandal or evil report as having offended against the said laws, it shall be lawful for the bishop of the diocese within which the offence is alleged or reported to have been committed, on the application of any party complaining thereof, or if he shall think fit, of his mere motion, to issue a commission under his hand or seal to five persons, of whom one shall be his vicar-general, or an archdeacon or rural dean within the diocese, for the purpose of making inquiry as to the grounds of such charge or report; provided always that notice of the intention to issue such commission under the hand of the bishop, containing an intimation of the nature of the offence, together with the names, addition, and residence of the party on whose application or motion such commission shall be about to issue, shall be sent by the bishop to the party accused fourteen days at least before such commission shall issue." The bishop may at once pronounce sentence, by consent of the clerk; and such sentence is good and effectual in law. If he refuse or neglect to appear and make answer to the articles alleged against him, other than an unqualified admission of the truth thereof, "the bishop shall proceed to hear the cause, with the assistance of three assessors, to be nominated by the bishop, one of whom shall be an advocate who shall have practised not less than five years in the court of the archbishop of the province, or a sergeant-at-law, or a barrister of not less than seven years' standing, and another shall be the dean of his cathedral church, or of one of his cathedral churches, or one of his archdeacons, or his chancellor; and upon the hearing of such cause the bishop shall determine the same, and pronounce sentence thereupon according to the ecclesiastical law." While the charge is under investigation, the bishop may inhibit the party accused from performing any services of the church within his diocese until sentence has been passed; but if the person accused be the incumbent of a benefice, he may nominate any person or persons to perform such services during his inhibition, and such persons are to be licensed by the bishop if they are approved of by him. Appeals under the Act are to the archbishop, and they are to be heard before the judge of the court of appeal in his province; but if the cause has been heard and determined in the first instance in the court of the archbishop, the appeal is then to the Queen in Council, and is to be heard before the Judicial Committee of Privy Council, and at least one archbishop or bishop must be present.

In matters of dispute between a diocesan and his clergy, an appeal lies to the archbishop of the province in all cases excepting curates' stipends (1 & 2 Vict. c. 106).

Rolle, an old authority, contended that the archbishop might appoint a coadjutor to one of his suffragans who is infirm or incapable. This power is now established by 6 & 7 Vict. c. 62, entitled "An Act to provide for the performance of the episcopal functions in case of the incapacity of any bishop or archbishop."

In 1841 a bishop of the United Church of England and Ireland was appointed for Jerusalem. The King of Prussia first suggested the appointment to Queen Victoria, and the right of appointing the bishop is enjoyed alternately by the crowns of Prussia and England; but the Archbishop of Canterbury has a veto on the selection by Prussia. The Bishop of Jerusalem is a suffragan of the Archbishop of Canterbury; but he cannot exercise episcopal functions in the dominions of Great Britain, nor can the persons ordained by him. The Protestant Church of Jerusalem comprehends persons using different liturgies and subscribing different articles of faith, who will be on terms of equality as

members. The bishop may ordain Prussian clergymen, on their signing the Augsburg Confession, and adopting the Prussian liturgy; and Englishmen, on their subscribing to our articles and liturgy. He is the legal protector of all Protestants of every denomination against the Turkish government. The Act 5 Vict. c. 6, was passed to enable the archbishops of Canterbury and York, and such bishops as they might select, to consecrate a foreign bishop.

At the present time there are twenty-four bishops of the Protestant Episcopal Church of the United States of America. In this Church the superior powers of church government are vested in a General or National Convention, which meets triennially. The Convention consists of two houses. The bishops sit as a body in their own right, and form a separate House. The lower House is composed of lay and clerical delegates. Each diocese is represented by four laymen and four of the clergy, who are elected by local Diocesan Conventions. The lay members of the Diocesan Conventions are elected by their respective congregations or vestries. The general Convention, amongst other things, has the power of revising old, or making new canons. It hears and determines charges against bishops; receives and examines testimonials from Diocesan Conventions recommending new bishops, and decides upon their appointment; without the certificate of the General Convention, a bishop cannot be consecrated. The title assumed by a bishop in the United States is "Right Reverend."

The bishops of the Methodist Episcopal Church of the United States have no particular province or district. Their time is chiefly spent in attending the different annual conferences of the Church.

The Roman Catholic hierarchy in the United States is composed of one archbishop, fifteen bishops, and five coadjutors. The first Roman Catholic bishop in the United States was consecrated in 1790.

The Pope is the bishop of the Christian Church of Rome, and claims to be the successor of St. Peter, of whom it is alleged that he was the first bishop of that Church, and that to him there was a peculiar authority assigned, not only over all the inferior pastors or ministers of the Church, but over the rest of the apostles, indicated to him by the delivery of the keys. The whole of this, the foundation of that superiority which the bishop of Rome has claimed over all other bishops, has furnished matter of endless controversy; and it does not appear that there is any sufficient historical authority for the allegation that St. Peter did act for any permanency as the bishop of that Church, or for the six or seven persons named as successively bishops of that Church after him. It seems more probable that the superiority enjoyed by the bishop of Rome at a very early period over other bishops (which was not universally acknowledged, and was strenuously opposed by our own Welsh bishops), resulted from his position in the chief city of the world, and the opportunities which he enjoyed of constant access to those in whom the chief temporal authority was vested.

England and Wales was, soon after the Reformation, divided by the Roman Catholic Church into "Districts," over each of which a bishop was placed, who was a bishop *in partibus*. [BISHOP.] But in 1850, in consequence of a rescript issued by the Pope, a complete hierarchy was directed to be formed in Great Britain. England has, therefore, been divided into the archbishopric of Westminster, and the bishoprics of Southwark, Hexham, Beverley, Liverpool, Salford, Shrewsbury, Newport and Menevia, Clifton, Plymouth, Nottingham, Birmingham, and Northampton. This assumption created considerable agitation; and in August, 1851, the Ecclesiastical Titles Assumption Bill (14 & 15 Vict. c. 60) was passed, by which all briefs or rescripts of the pope conferring any such jurisdiction or title was declared void; any person publishing such bull or rescript, or acting on it, or assuming the title of archbishop or bishop of any city or place within the United Kingdom, was rendered liable to a penalty of 100*l.*, to be recovered in a court of law, but only with the consent of, or by, the Attorney-General in England or Ireland, and the Lord Advocate in Scotland. There has been no conviction under this Act.

In Scotland there are three Roman Catholic bishops, but there they continued to be bishops *in partibus*; they are the Bishop of Limyra for the Eastern district, the Bishop of Castabala for the Western district, and the Bishop of Germanicia for the Northern district.

The Roman Catholic hierarchy in Ireland consists of four archbishops and twenty-four bishops. In the Charitable Donations (Ireland) Act (7 & 8 Vict. c. 97) the Roman Catholic prelates were designated for the first time since the Reformation by their episcopal titles, which are taken from the same sees as those of the English Church, except Galway, which is not included among the English sees. They had been referred to in the bill, when first brought in, as "any person in the said Church [of Rome] of any higher rank or order," &c.; and, on the proposition of the government, this was altered to "any archbishop or bishop, or other person in holy orders, of the Church of Rome." In December, 1844, a royal commission was issued constituting the Board of Charitable Bequests in Ireland, and the two Roman Catholic archbishops and bishop who were appointed members of the Board were styled "Most Reverend" and "Right Reverend," and had precedence according to their episcopal rank; but they were only styled archbishop or bishop with their proper names, not with the addition of any see.

It is stated in a recent authority that the number of Roman Catholic archbishops in Europe is 108, and of bishops 469; and that there are 154 bishops in other parts of the world; making a total of 731 bishops. In France there are 14 archbishops, and 66 bishops.

The Eastern or Greek Church is also framed in an episcopal form and order, and the sees are very numerous.

BISMETHYL, *Bismuthethyl*. [ORGANOMETALLIC BODIES.]

BISMUTH (Bi). This metal occurs in nature either in the free state, as native bismuth, or as oxide, carbonate, sulphide, or telluride. Native bismuth, which furnishes almost all the metal employed in the arts, is found in the clay-slate and gneiss formations, generally associated with silver, lead, zinc, cobalt, or nickel, and containing variable quantities of arsenic and iron. It crystallises in cubes and octohedra, and in arborescent forms derived from these, its colour being a very light grey inclining to red. Native bismuth is found in Cumberland and Cornwall, but its principal source is Schneeberg, in Saxony, where it accompanies the silver and cobalt ore. The extraction of native bismuth from the matrix is conducted at Schneeberg as follows: The fragments of rock richest in the metal are reduced to pieces about the size of a hazel nut. It is then introduced into a series of cast-iron tubes, arranged parallel to one another in an inclined position. Each end of every tube is closed by a plate of clay, a hole being left at the bottom of the lower clay-plate of every tube for the egress of the melted metal. On bringing the tubes to a white heat, the metal flows out and falls into cast-iron cups, which are kept sufficiently hot to retain the bismuth in a state of fusion. From these cups the bismuth is ladled into ingot moulds. In order to free the metal from arsenic and iron, with which it is contaminated, it is submitted to a fresh fusion with nitrate of potash; the foreign metals are thereby oxidised, and dissolve in the slag. If a crucible full of fused bismuth be allowed to cool slowly, the solid crust which forms on its surface be broken through, and the still fluid portion be poured out, the inner surface of the solidified portion is found covered with crystals of bismuth, of the cubic and derived forms, of great regularity. The iridescence which such bismuth shows, is owing to the edges of the successively-formed layers of metal not being in one plane. On solidifying from a state of fusion, bismuth undergoes an expansion of about $\frac{1}{32}$ of its volume; this property renders the alloys of bismuth (to which it imparts the same peculiarity) of great value for taking sharp castings, as in the manufacture of type; for such an alloy, at the moment of solidification, is forced into the minutest crevices of the mould. Cast bismuth has the specific gravity 9.86; but after being submitted to enormous pressure, its density is diminished to 9.65. Bismuth is so brittle as scarcely to admit of extension under the hammer. It melts at 497° F., when heated alone; but it depresses the melting point of many metals with which it is alloyed. The solder used for pewter consists of 1 part of bismuth, 5 of lead, and 1 of tin. Fusible metal, which melts at 199° F., contains 5 parts of bismuth, 3 of lead, and 2 of tin. A similar alloy, of higher melting point, is sometimes employed to form safety-plugs for boilers.

There is some uncertainty respecting the atomic weight of bismuth, and consequently as to the composition of its oxides, &c. The analogy between bismuth and antimony makes it probable that these two metals combine with oxygen in the same proportion. According to this, the protoxide of bismuth is BiO_2 , and the equivalent of the metal between 213 and 210.

There is probably no lower oxide of bismuth than the teroxide. When the metal oxidises in moist air, or when it is made to form the positive pole of a battery in a solution of a fixed alkali, it becomes covered with coatings of oxide of various colours. On treating the film so formed with hydrochloric acid, it is converted into metallic bismuth and teroxide.

Teroxide of bismuth (BiO_3) is produced when air has access to melted bismuth. Most salts of the teroxide, as the nitrate and carbonate, when heated, give off their acids, and leave the teroxide in the form of a dark orange-yellow powder, which becomes nearly white on cooling. The hydrated teroxide is precipitated as a white powder by decomposing a soluble salt of bismuth by a fixed alkali or by ammonia. If, however, the chloride be employed, the precipitated bismuth contains chlorine, probably in the form of oxychloride.

The teroxide of bismuth combines with various proportions of acids; of the salts resulting from such combination, those which contain most acid are more soluble than those which contain an excess of base. Most of the solutions of the acid bismuth salts are decomposed by water, less soluble basic salts being formed, and in most cases precipitated, owing to their inferior solubility. This property is of much value as a test for bismuth. Teroxide of bismuth combines with sulphuric acid in four proportions. The *tersulphate* ($\text{BiO}_3\cdot 3\text{SO}_3$) is formed when metallic bismuth is heated with oil of vitriol, sulphurous acid and sulphur being at the same time liberated; the tersulphate of bismuth so formed is a white mass which is decomposed by water into a salt which dissolves, and which contains more acid than the tersulphate, but whose composition is undetermined, though it may be obtained as acicular crystals by evaporation; and the *monosulphate* ($\text{BiO}_3\cdot \text{SO}_3$), an insoluble white powder, which becomes yellow on heating. The same monosulphate may also be formed by dissolving the teroxide in sulphuric acid, and evaporating and gently igniting the solution. The *bisulphate* ($\text{BiO}_2\cdot 2\text{SO}_3\cdot 3\text{HO}$) separates out in the crystalline form on decomposing the acid nitrate of bismuth with sulphuric acid; it is decomposed by water. Hydrated teroxide of bismuth combines with sulphurous acid, and gives rise to a white insoluble sulphite, which gives up its acid on ignition.

Nitric acid combines with teroxide of bismuth in three proportions. If metallic bismuth, or the teroxide, be treated with nitric acid in excess, a soluble ternitrate of bismuth is formed (in the former case with evolution of nitrogen oxides), if the acid be not too dilute. On evaporating such a solution of ternitrate in nitric acid at a gentle heat, colourless transparent prismatic crystals are formed, containing nine or ten equivalents of water. Both the crystallised ternitrate and its solution in nitric acid may be dissolved in nitric acid without decomposition. Water decomposes the salt in both conditions; the amount of decomposition effected in the latter case depending upon the quantity of free nitric acid present. The white powder thrown down by water from a solution of the ternitrate is the mononitrate $\text{BiO}_3\text{NO}_5 + \text{HO}$, which is the Bismuth-white or Pearl-white of the arts, also called the Magistery of Bismuth, and used as a cosmetic. It is prepared commercially by boiling dilute nitric acid with bismuth until no more is taken up, adding water until a precipitate begins to form, filtering, and adding from 30 to 100 times as much water by weight as there is metallic bismuth in solution. The precipitated mononitrate is collected on a filter, washed with cold water, and dried between blotting-paper. It is a white powder, of pearly lustre, and crystalline constitution. According to Becker ('Ann. Pharm.' 68, 282), nitric acid combines with bismuth in three other proportions, namely, $5\text{BiO}_3\cdot 4\text{NO}_5 + 9\text{HO}$ (and $5\text{BiO}_3\cdot 4\text{NO}_5 + 12\text{HO}$), $6\text{BiO}_3\cdot 5\text{NO}_5 + 9\text{HO}$, and $4\text{BiO}_3\cdot 3\text{NO}_5 + 9\text{HO}$.

The teroxide of bismuth forms salts with ordinary bibasic and monobasic phosphoric acids; these bodies, however, have been but little examined. The same may be said of the bromate and iodate; the former, obtained by treating hydrated teroxide with bromic acid, has the composition $3\text{BiO}_3\cdot 2\text{BrO}_5 + 6\text{HO}$, and is insoluble (there is also a more acid bromate); the latter, formed by double decomposition, is a white powder, insoluble in water.

Carbonate of bismuth occurs in nature. The composition of the native carbonate is doubtful. A monobasic carbonate is precipitated as a white insoluble powder, on mixing a solution of the nitrate with one of an alkaline carbonate; its composition is $\text{BiO}_3\text{CO}_2 + \text{HO}$.

Boracic and Silicic acids combine with the teroxide of bismuth, both are insoluble in water; the former is obtained by double decomposition, the latter occurs in nature as bismuth-blende ($\text{BiO}_3\cdot 2\text{SiO}_3$), in minute dodecahedral crystals of dark yellow colour, contaminated with arsenic, cobalt, copper, iron, and manganese.

Quadroxide of Bismuth (BiO_4) is a brown powder, formed by boiling the hydrated teroxide with the chlorite of an alkali containing an excess of alkali. If teroxide of bismuth be thrown upon fused caustic potash it dissolves, and undergoes further oxidation by the oxygen which the potash acquires from the air. After cooling, the mass is exhausted with water, which removes the excess of potash, and leaves a yellow insoluble body of the composition $\text{KO}_6\text{BiO}_3\cdot 2\text{BiO}_3$, being the bismuthate of bismuth and potash. Brown and purple compounds of potash with the ter- and pent-oxides of bismuth have been also formed.

Pentoxide of Bismuth, or bismuthic acid (BiO_5), is formed by fusing hydrate of soda with teroxide of bismuth; boiling the product with caustic soda, and washing the brown powder so formed, which is probably a bismuthate of bismuth and soda, with nitric acid, which removes the teroxide and soda, and finally with water. Bismuthic acid is a brown powder, which gives off oxygen when heated alone, or when treated with sulphuric or phosphoric acids. It evolves chlorine from hydrochloric acid; in all cases being reduced to the teroxide.

It is doubtful whether bismuth combines with hydrogen alone. If bismuth form the negative pole of a battery in a decomposition cell containing water, a black arborescent crust is obtained.

The most important haloid compounds of bismuth are the chloride, bromide, iodide, and sulphide.

Chloride of Bismuth (BiCl_3). Powdered bismuth, when thrown into dry chlorine gas, takes fire, burning with a blue flame, and forming a gray-white, granular, easily fusible mass, which may be volatilised without decomposition in an atmosphere of carbonic acid. The same substance is formed by dissolving the teroxide in hydrochloric acid, evaporating, and distilling. The vapour density of terchloride of bismuth is 11.35. By gently evaporating a solution in hydrochloric acid, a crystalline terhydrate of the terchloride is formed. Both the anhydrous and hydrated chlorides are decomposed by water, a portion of the bismuth being precipitated as Oxychloride of bismuth ($\text{Bi}_2\text{Cl}_3\text{O}_6$), a white crystalline powder, fusible at a red heat. The same oxychloride may be formed by precipitating ternitrate of bismuth with hydrochloric acid, or an alkaline chloride.

Bromine does not act so energetically as chlorine upon bismuth. To effect the union of the two, powdered bismuth is heated in a tube with an excess of bromine. The terbromide of bismuth (BiBr_3) so formed is freed from excess of bromine by a gentle heat. On cooling, the pure terbromide solidifies to a grey mass of submetallic lustre. It fuses at 392°Fahr. , and volatilises at a red heat. It abstracts the water from moist air, and is converted into a hydrate. Like the chloride, it is decomposed by a larger quantity of water, oxybromide of bismuth being in this case formed.

Teriodide of bismuth (BiI_3). If a solution of iodide of potassium be added to a soluble salt of the teroxide of bismuth, and the formation

of basic salts hindered by the addition of acetic acid, a brown crystalline body separates out; this is the teriodide of bismuth. The teriodide is slowly decomposed by cold water; boiling water decomposes it quickly, a red insoluble oxyiodide ($\text{Bi}_2\text{I}_3\text{O}_6$) being formed. Teriodide of bismuth dissolves in aqueous hydriodic acids; evaporation of such a solution yields the hydrated hydriodate of the teriodide ($\text{BiI}_3\cdot\text{HI} + 8\text{HO}$).

Lower iodides of bismuth, containing less iodine than the teriodide, are formed by heating iodine with powdered bismuth; their composition is doubtful.

Sulphur combines in two proportions with bismuth. The bisulphide of bismuth (BiS_2) is obtained in the form of quadratic prisms, of grey metallic lustre and of specific gravity 7.29, by fusing 10 parts of powdered bismuth with 3 parts of sulphur, and again fusing the mass so obtained two or three times with fresh portions of sulphur. On quickly cooling from the last fusion, a nest of crystals of the bisulphide are found in the interior of the mass.

The tersulphide of bismuth, BiS_3 , occurs in nature as bismuth glance. It is formed artificially by precipitating bismuth from solutions of its tersalts with sulphuretted hydrogen. If sulphur and bismuth be fused together this compound is also formed; but all these varieties of the tersulphide lose sulphur when heated, being reduced to the bisulphide. Bismuth glance is of a lead grey colour, of specific gravity 6.5; it belongs to the right prismatic system.

Selenium, phosphorus, antimony, arsenic, and tellurium, combine directly with bismuth in indefinite proportions, as also do the metals potassium and sodium.

If the point of contact of two bars, one of bismuth and the other of antimony, be heated, and the other extremities metallically connected, an electric current circulates through the system. A series of such pairs constitutes the thermomultiplier.

For the organic compounds of bismuth, see ORGANO-METALLIC BODIES.

Bismuth in solution may be distinguished from all other metals by the conjunction of the following reactions:—1. It is precipitated from acid solutions by sulphuretted hydrogen. 2. The sulphide is insoluble in alkalies and their sulphides. 3. The sulphide is soluble in nitric acid. 4. The chloride is soluble in dilute hydrochloric acid. 5. The oxide is precipitated by ammonia from the ternitrate, terchloride, or tersulphate, and is insoluble in excess of that reagent. 6. All soluble salts are decomposed on being dropped into a large quantity of water, insoluble basic salts being formed.

BISMUTH, MEDICAL USES OF. Bismuth taken into the stomach in the state of a metal produces no effect upon the human system. It is therefore in the form of one of its preparations that it is employed as a medicinal agent; and for this purpose the sub-nitrate, called also the magistery of bismuth, and also, incorrectly, the white oxide of bismuth, is generally preferred. This is a white powder, sometimes in lumps resembling chalk, inodorous and tasteless. It is insoluble in water, and but slightly if at all soluble in the juices of the stomach, a circumstance which accounts for its limited sphere of action; hence its employment is almost entirely confined to affections of the stomach itself. In large doses, however, it is undoubtedly poisonous, and produces vomiting, with small pulse, faintings, and even death, the stomach exhibiting erosions and signs of inflammation. Even its external application is not free from danger, for the cosmetic termed *pearl white*, or *Spanish white*, which is subnitrate of bismuth, when applied for a length of time to the face, causes nervous twitchings, and finally paralysis. Subnitrate of bismuth is considered a tonic, and in nervous pains and cramps of the stomach it is decidedly antispasmodic. In what is termed *gastrodynia*, either given alone, or with one grain of opium, it is in general more efficacious than any other means in speedily removing the pain. It is also sometimes useful in *pyrosis*, especially if complicated with affections of the pancreas. In this case it is advantageously combined with rhubarb. Extract of hops is also an appropriate vehicle for it. In combination with magnesia it is stated by Dr. Theophilus Thompson to be useful in the diarrhoea of phthisis pulmonalis. Being insoluble in water it can never be administered in that vehicle.

Its employment has been proposed in hysteria, tetanus, and intermittent fever, but its utility is very slight when the cause of these diseases is remote from the stomach. In case of an overdose, tea, white of egg, or milk, are the best antidotes. As *pearl white* is blackened by sulphuretted hydrogen, the face of those who employ this cosmetic is blackened by the use of the Harrowgate or other sulphureous waters.

BISMUTHIC ACID. [BISMUTH.]

BISSEXTILE, or BISSEXTUS DIES, the name given in the Roman calendar, after its reformation by J. Caesar, to the intercalary day which was inserted every fourth year between the 24th and 25th of February. The 24th of February was expressed according to the Roman reckoning, "sexto Calendas Martii,"—that is, the sixth day before the Calends, or first of March. When the intercalary day was inserted it was also called "sexto Calendas Martii;" and as the name was thus repeated, this day was called the *bissextus dies*, or the sixth day twice over. In legal reckoning, as to the birth of a child, the 24th and following day in the bissextile year were considered in the Roman law as one day. (See 'Dig.' 4, tit. 4. 3.) In Greek, this day was called *ἐμβόλιμος ἡμέρα*, which signifies the same as intercalated day.

By the statute 21 Hen. III., the bissextile day and the day immediately preceding were to be considered legally as one day (*computetur dies ille et dies proxime precedens pro uno die*). In the English calendar the intercalated day in each leap year is placed at the end of February, which has twenty-nine days. [YEAR.]

BISTORT [*POLYGONUM BISTORTA*, or *SNAKEWEED*; NAT. HIST. DIV.] is an indigenous perennial plant, growing in woods and meadows. The root, which is the officinal part, is about the thickness of a finger, round or flattish, and much twisted, like the coils of a snake, externally dark brown, within red and fleshy. When dried, it has no smell, but a very astringent taste. Roots of plants a few years old should be taken up in spring or autumn. It consists chiefly of tannin, gallic acid, starch, and oxalate of lime. It was formerly given in diseases of debility accompanied with sanguineous or mucous discharges, and likewise fevers, especially intermittents, for the cure of which it may be combined with gentian, or sweet flag-root. It is to be regretted that an indigenous remedy of such power has fallen into neglect. It can be used in dyeing. The large quantity of starch renders it nutritive. It is cultivated and eaten in Siberia, and other northern countries.

BISTRE, a brown pigment made from the root of different kinds of wood, but that of beech is preferred by some who have given directions for making it. One recipe for preparing it is as follows:—Put the soot of any wood (of beech when it can be procured) into water, in the proportion of two pounds to a gallon, and boil them for half an hour. Then, after the fluid has stood some time to settle, but while it is yet hot, pour off the clearer part from the earthy sediment at the bottom; and if on standing any longer it form another earthy sediment, repeat the same method; but this should be done only while the fluid remains hot. Evaporate the fluid to dryness; and what remains will be good bistre, if the soot was of the proper kind. It is then mixed with a little gum-water and made into small cakes. As a colour it is perfectly permanent.

According to the late Dr. McCulloch, bistre is a very variable article, and is often unfit for use, and he concluded from his experiments, that this is owing to its too near alliance to tar, and hence the disagreeable gumminess which it frequently possesses. He proposed a process for removing the defects which he pointed out, by preparing it from the pitch of distilled wood. ('Trans. Geol. Soc.' vol. ii. p. 1.)

BISUCCINAMIDE. — *Disuccinamide*. — *Succinamide* — $(C_8H_5NO_4)_2 = N \left\{ \begin{matrix} (C_8H_4O_4) \\ H \end{matrix} \right.$. An amide formed by the distillation of succinate of ammonia. [AMIDES.]

BISULPHIDE OF AMYL ($C_{10}H_{11}S_2$). An ethereal liquid, possessing a fetid odour, and consisting of one equivalent of the radical amyl, combined with two equivalents of sulphur. [AMYL.]

BISULPHIDE OF CARBON. [CARBON.]

BISULPHIDE OF ETHYL. [ETHYL.]

BISULPHIDE OF ETHYLENE, *Bisulphide of Etherine* ($C_4H_4S_2$). When chloride of ethylene is digested for some days with an alcoholic solution of bisulphide of carbon, a white powder is formed, which possesses the above composition.

BISULPHISATIDE. [INDIGO.]

BITTER PRINCIPLE. When indigo and some other vegetable products are acted upon by nitric acid a substance is produced, which, before its properties had been accurately examined, was called, on account of its taste, bitter principle. This is now, however, known to be a peculiar acid, and is called carbazotic or nitropicric acid, and will be mentioned hereafter under the former name.

Besides this artificial product, there exist a vast number of vegetables, most or all of which are used in medicine, that contain bitter extractive matter, and from which a peculiar bitter principle may in many cases be separated.

These bitter substances have been little examined chemically, and they doubtless include bodies of very different composition. The following list comprises a number of these substances with the derivation of each:

Absinthin, flowers of *Artemisia absinthium*.

Aloin, *Aloë spicata*.

Bryonin, root of *Bryonia alba*.

Cathartin, leaves of *Cassia lanceolata*.

Cetrarin, *Cetraria islandica*.

Colocynthin, seed-pulp of *Cucumis Colocynthis*.

Columbin, root of *Menispermum palmatum*.

Cusparin, bark of *Galipea cusparia*.

Daphnin, *Daphne megereum*, &c.

Elaterin, fruit of *Momordica elaterium*.

Ergotin, Ergot of rye.

Frazinin, bark of *Fraxinus excelsior*.

Gentianin, root of *Gentiana lutea*.

Hesperidin, spongy part of orange rind.

Ilicin, leaves of *Ilex aquifolium*.

Lactucin, *Lactuca sativa*, &c.

Liriodendrin, root-bark of *Liriodendron tulipifera*.

Lupulin, female flowers of *Humulus lupulus*.

Olivil, gum-resin of *Olea Europea*.

Olinin, leaves of *Olea Europea*.

Pichrolichenin, *Variolaria amara*.

Picrotoxin, *Menispermum cocculus*.

Phyllyrin, bark of *Phillyrea media*.

Quassiin, wood of *Quassia amara*.

Scillitin, bulb of *Scilla maritima*.

Tanacetin, *Tanacetum vulgare*.

Tanghinin, seeds of *Tanghina Madagascariensis*.

Xanthopierin, bark of *Xanthoxylon Clava Herculis*.

BITTERN. A name given to the mother liquor from which common salt has crystallised by the evaporation of sea-water. It contains much sulphate of magnesia, and is used for the manufacture of that salt.

BITTERS, a collective term applied to those vegetable substances the most prominent sensible quality of which is *bitterness*. "Bitterness," says Dr. Cullen, "is a simple perception that cannot be defined, but must be referred to a matter of experience in which mankind are commonly agreed." It was at one time attempted to refer this quality to an hypothetical principle, which was termed *bitter principle*; but it was soon perceived that substances having a bitter taste were indebted for it to very different sources. In the progress of science this term was limited to such natural non-azotised substances as possessed the general character of *extractive*, which was designated bitter extractive, and subdivided into mild bitter, sharp bitter, and narcotic bitter extractive. More recently, the pure non-azotised substances, to which many plants are indebted for their bitterness, have been obtained separately, and even crystallised, such as gentianine, salicine, &c. But bitterness is not confined to vegetable substances destitute of nitrogen, but is possessed by many alkaloids, into the composition of which nitrogen enters, such as quinia, strychnia, brucia, &c. As some of these constitute valuable medicinal agents, as well as the non-azotised substances, it seems improper to adopt a chemical arrangement of these articles as the foundation of our observations. Any bitter substance taken into the mouth produces instantly a sensation which on the first trial is seldom relished, but to which the taste soon becomes reconciled, so that most persons can continue the use of bitter longer than sweet substances. This impression on the organs of taste seems to have little general effect beyond causing a secretion of saliva in most individuals, and it is not till they reach the stomach that they produce much effect. Upon the mucous membrane and muscular fibres of the stomach, as well as upon the neighbouring glands associated with it in the function of digestion, especially the liver and pancreas, they produce a very decided effect. Gummy matter, which forms a considerable portion of most vegetable food, does not easily submit to the action of the digestive organs, but frequently passes through the intestines very little changed. But when associated with bitter extractive it is soon digested, and yields a large quantity of nourishment. Saccharine matter or sugar is not, when existing alone in vegetable food, adequate to the support of the animals which feed upon it, but they become plump and healthy if any bitter matter exist in the plants along with the sugar, or if they have access to other plants almost exclusively bitter, to which they eagerly resort. Where there is a deficiency of bitter matter, and the food is of a very watery kind, such as grows in wet pastures, the cattle suffer from various diseases, especially from the rot.

That bitters develop and heighten the vitality of the stomach seems clear, and in popular language they are called *stomachics*. But they also cause an increased secretion of the juices of the stomach essential to digestion, and also of the bile and pancreatic juice. The secretions are also improved in quality, and when previously excessive may even be diminished in quantity, as a greater degree of firmness and tone is imparted to the whole intestinal canal, by which hasty and imperfect secretion is prevented. The beneficial effects of this improved condition of the stomach are extended to the rest of the system by two means, the first, sympathy, which is speedy in its action; the second, more slow, being the result of the improved blood obtained from better digestion being distributed through the system. The nature of sympathy is little understood, but the effects of that disposition or consent of parts to act in concert or harmony, which physiologists have agreed to term sympathy, are sufficiently manifest. The stomach has been called the centre of sympathy, from its influence upon every organ of the body, and of most organs of the body upon it, according to their respective condition. But by a well-ascertained law of the system the sympathies of the stomach are greatest with those parts the constituents of which are similar to its own: hence mucous surfaces and the muscular fibres throughout the whole body participate in its changes more extensively than other parts. Hence by improving the state of the stomach and intestinal canal every muscle and every artery, for they as well as the heart are muscular tubes, acquire an increased tone, by which the elasticity and energy of the system is greatly augmented. By the improved digestion of the food, a better kind of blood containing more fibrine and red particles is circulated, and conveyed to every part of the body, by which not only better materials are supplied to the glands, out of which to form the secretions, but from which a firmer and better flesh is deposited; and thus the individual finds his strength much increased. The nervous system likewise partakes of the benefit, and the mind is in general clear and active.

Such being the common effect of the use of bitters, some writers regard them as synonymous with tonics; but as all tonic medicines are

not bitter, such, for example, as arsenic, this view cannot be taken, though many of the most valuable tonics are bitter. They have this property in common with most tonics: that their continued use seems to impair the power of the stomach, and leave it in a state of greater weakness than at first. Hence their employment should only be temporary, to raise the powers of digestion when they have been enfeebled by previous disease or excessive fatigue. There exists another reason for caution in their use: they have a great tendency to increase the quantity of blood, both by augmenting the appetite, owing to which more food is taken, and from which a more nutritive and stimulating chyle is extracted, by which a plethoric state of the blood-vessels is induced, and all the attendant evils brought about. These cautionary remarks apply as well to malt liquors as to those bitters unassociated with any nutritive matter which are only employed as medicines. The full and often bloated habit of body of those who daily consume a large portion of strong ale or porter sufficiently demonstrates the consequences of such indulgences. Besides, hops possess, like many other bitters, more or less of a narcotic principle, so that the purest beer produces an injurious effect on the brain, if taken in considerable quantity. The sleepiness which follows its use shows this, as well as the fate of those who are addicted to it. "In seven cases out of ten, malt-liquor drunkards die of apoplexy or palsy." A very moderate use, during dinner, of a beer not containing so much nutritious matter, or too much hop, is allowable to most persons, but it should be thoroughly fermented and purified, and not be hard or stale.

Persons naturally of a full habit of body should carefully avoid the stronger ales and porters. These remarks do not apply to the medical employment of strong ales as a tonic or restorative during convalescence from acute diseases, as few agents so speedily recruit the exhausted powers, or replace the wasted flesh of the sufferer. Neither are they intended to prohibit mothers while nursing from making a moderate use of them, since at that time there is a demand upon the system for an extraordinary quantity of highly nutritive blood, and the infant generally removes any superfluous quantity; but an excessive use of very strong beer is not less hurtful to the mother than the child.

Bitters may be advantageously employed by the inhabitants of cold and damp regions to prevent the action of these causes of disease. These agents generally injure the function of digestion, both by their immediate action on the skin, and also, from abstracting the animal heat, on the nervous system: hence the prevalence of intermittent fevers or agues in such districts. Now these may be warded off by maintaining a healthy action of the digestive organs and of the skin. Some preparation of a pure bitter, such as gentian, or of an aromatic and bitter united, such as chamomile with sweet flag-root, or infusion of milfoil or yarrow, may be had recourse to for this purpose; but if there be obstruction of the liver with ague-cake, which is the enlarged and hardened spleen, dandelion, having beef-tea poured upon it, and used as a soup, is preferable, in which way it is extensively employed by the Dutch. In the West Indies, where languor of the system, with weakness of the digestive organs, is produced by the excessive heat, the appetite is restored and the stomach invigorated by taking before dinner a few drops in a glass of water, of Stoughton's elixir, which is made of gentian, serpentaria, orange-peel, and sweet flag-root; and in America, the infusion or tincture of serpentaria is sometimes taken every morning in damp aguish situations to prevent intermittents. Such employment of bitters, within certain limits, is wise and proper.

During spring and autumn, when the sources of intermittent fevers are most abundant, the use of such bitters as those above mentioned would be very serviceable in the case of weak and feeble persons residing in aguish districts; but there may be weakness of the digestive organs, and general debility, accompanied with a state of stomach which forbids the employment of bitters or any other tonic. Inflammation of the stomach, from its slightest to its most intense degree, is always attended with a sense of weakness, which prompts many persons to betake themselves to bitters or other stimulating articles, which never fail to aggravate the disease. Such cases demand a widely opposite course of treatment.

There is another malady to which feeble persons are subject, the evils of which are much lessened by the use of bitters. Worms are rarely developed except in persons with impaired digestion, in which case bitters form, along with proper dietetical means, the most appropriate instruments of cure. [ANTHELMINTICS.] Much diversity of opinion exists with respect to the propriety of using bitters by persons subject to gout. Of late years the once famous Portland gout-powder has fallen greatly into disuse, partly because a more certain remedy has been discovered, and partly because one of the charges brought against it had some foundation in truth. It was said to cure the gout, but in a short time to carry off the patient by apoplexy. Now such a result was certainly the indirect effect of this tonic powder; for, as by the immunity from paroxysms of gout, which the use of it for a time conferred upon the patients, they were enabled to indulge their increased appetites, a plethoric state of the system was brought on, which in many cases induced apoplexy, in which disease gout has a tendency to terminate. This powder consisted of serpentaria, gentian, germander, and lesser centaury.

Where the disposition to gout is very strong, some of the most experienced practitioners condemn the use even of ale. Still it must be allowed that many persons who have no disposition to excessive indulgence in the good things of the table, have such slow and troublesome digestion as to render tonic and aromatic stimulants useful; but it is best to unite these with some gentle laxative, by which the plethoric tendency is lessened. For this purpose, orange-peel, rhubarb, and magnesia, united in equal portions, form a fitting combination. Gout and stone in the bladder are so closely allied, and the means which are useful in repelling them are so similar in many instances, that they are naturally treated of together: the origin of both is depraved digestion. In full livers this is accompanied with deficient secretion of urine, and a tendency to the formation of uric acid, by which red gravel is voided. Here bitters with alkalies are eminently useful, such as quassia with lime-water, or colchicum with magnesia. In very feeble persons, and also after the long continuance of the uric acid diathesis, and the irritation of a stone in the bladder, an opposite state prevails, namely, an alkaline state of urine, in which it is excessive in quantity, pale, and on standing some time, becomes covered with an iridescent pellicle, or lets fall a white, generally amorphous sediment. In such a case bitters are extremely useful, especially infusion of quassia with phosphate of iron, or infusion of quassia with nitric acid; the extract of *Arctostaphylos Uva Ursi* (bear-berry).

In phthisis pulmonalis bitters are sometimes of service, such as the bear-berry and the Iceland moss (*Cetraria Islandica*), in which the bitter principle should be retained.

In some cases of diarrhoea, from loss of tone of the intestines, bitters are of the greatest service, provided no inflammatory condition of the mucous membrane exist, such as quinia, infusion of cusparia, or even strychnia, perhaps the most intensely bitter substance with which we are acquainted.

The most eligible form for exhibiting bitters is in powder or infusion, but where the taste is objected to, an extract may be given formed into pill. Decoction is a bad form, especially for aromatic bitters. Aromatic principles frequently conceal the disagreeable taste of bitters.

BITTERS. Irrespective of the use of bitter plants for medicinal purposes, there are certain beverages known by the name of bitters. In England, the "bitters" of the spirit-shops are made of brandy, orange-peel, gentian, cassia, cloves, or some other spice, sugar and one or two other ingredients. Many beverages known in foreign countries are more or less analogous to these English "bitters." Thus, the Swiss peasants, inhabiting some of the highest Alpine villages, which are almost constantly wrapped in a penetrating mist, use a spirit distilled from gentian, called bitter schnaps. In France a decoction of wormwood, which is called absinthe, is a very favourite drink; and the mint juleps and other mixtures of the citizens of the United States, depend on the same principle, that of acting as gentle tonics, for their general adoption; and the various modes of preparation are merely used in order to avoid the disagreeableness to the taste of the unadulterated bitter.

BITUMEN. The name bitumen is applied to certain naturally occurring solid or viscous hydrocarbons which are usually of a black or brown colour, possess a peculiar somewhat tarry odour, and are fusible at temperatures below a red heat. It is uncertain how bitumen has been formed, some chemists regarding it as a product of the putrefaction of vegetable matter at ordinary temperatures; as the result in fact of a modification of that natural process of decay, which under ordinary circumstances converts woody fibre into peat, lignite, and coal; whilst others contend that it is a product of the destructive distillation of coal occasioned by the exposure of coal-bearing strata to volcanic heat; the latter view derives considerable probability from the fact that analogous substances are produced by the artificial destructive distillation of coal. Deposits of bitumen are met with in England, France, Switzerland, Germany, Russia, Poland, and America. The most remarkable bituminous deposits in this country occur in Derbyshire, where a thin stratum of bitumen is met with immediately underlying the turf of the grass pastures in the mountain limestone district, and encrusted with beautiful crystals of protosulphate of iron. This Derbyshire bitumen is elastic like caoutchouc, it is soluble in naphtha and essential oils, and when submitted to a red heat, yields a large quantity of highly illuminating gas. Although a considerable quantity of it has been stored up in the Derbyshire caverns, it has not yet been applied to any useful purpose.

The experiments of M. Boussingault show that glutinous and elastic bitumens consist of two principles, one of which he calls *Asphaltin* [ASPHALT], and the other *Petrolin*; the former is fixed, the latter volatile. Petrolin may be obtained by distilling bitumen with water. Rectified from chloride of calcium, petrolin presents the appearance of a pale yellow oil, possessing a bituminous odour, and a specific gravity of .891. It boils at 535° Fahr., and has the composition $C_{40}H_{32}$. It is therefore isomeric with oil of turpentine. The harder descriptions of bitumen are undistinguishable from asphalt, and are used for similar purposes; the softer varieties frequently contain paraffin, and might probably be utilised for the extraction of this substance.

BITUMENS, MEDICAL USES OF. Though the substances popularly termed bitumens, in the most extensive use of the term,

differ, as stated above, yet as in medical writings the term is restricted to certain forms of these, a slight notice of their uses and modes of action may here be most appropriately introduced. In this limited sense bitumens comprise naphtha, petroleum, and asphaltum, which are all transition states of the same thing, from naphtha the most fluid, to asphaltum the most solid. These appear to be all mixtures in different proportions of naphtha (strictly called *naphtha montana*), paraffine, creosote, acetic acid, and of some substance which easily becomes black by the action of the air. The chief constituent principles are carbon and hydrogen. They may be considered mineral empyreumatic oils, and in their action on the human system they are similar to balsams and resins. Their sphere of action does not seem to extend beyond the spinal chord and ganglionic system; they do not affect the brain or its nerves, except indirectly in case of an overdose, through the vitiated and imperfectly carbonised blood. The functions dependent for their perfection on the nerves of organic life are more powerfully affected by these agents than by any other empyreumatic oil. The secretions of the mucous membranes, of serous membranes, and glandular structures, as well as the skin, are promoted by their influence. The process of absorption is also increased, and a more copious secretion of urine takes place. They are better suited for slight and chronic affections of the nerves of organic life, than for acute or violent disorders of them. They have been employed in loss of power, cramps, and chronic affections of a nervous but obscure nature; also in affections of the mucous membranes of the lungs, when balsamic medicines are proper, such as humid catarrh, and some of the forms of asthma arising from nervous debility. Likewise in similar states of the bladder, such as atony of that organ, loss of power of its sphincter muscle, catarrhus vesicæ, &c. They have also been used in gouty and rheumatic affections, especially when these threaten to terminate in stiffness or loss of power. Lastly, they have been employed as a remedy against worms, especially the tape-worm, in which their efficacy is increased by combination with asafœtida. Externally they are used as embrocations in rheumatic and gouty affections, and also to allay cramps and spasms. They are also serviceable as an external application to chilblains, and some other ulcers resulting from an imperfect circulation and low degree of nervous power.

Their employment would be very improper during any inflammatory state of the system, or increased sensibility of the nerves. An overdose is decidedly poisonous, causing general excitement, tremblings of the limbs, cramps, convulsions, laborious respiration, a venous state of the blood, great debility, and death: or recovery may take place, if by means of respiration and a copious secretion of bile and urine, the blood can be freed from its excess of carbon. Even after a favourable issue appears likely to occur, death may take place at the end of two or three days. A very large dose may very speedily cause death. [CREASOTE; PARAFFIN; PETROLEUM.]

BIURET. ($C_4H_5N_3O_4, 2Aq. = HO, NH_4O, 2CyO, 2Aq.$) When urea is fused and exposed for some time to a temperature of about 230° Fahr., it evolves a large quantity of ammonia and leaves a pasty residue, which nearly dissolves in a very small quantity of boiling water. This solution must be passed through a filter, and then precipitated by subacetate of lead. The precipitate must be separated by filtration and the liquid treated with sulphuretted hydrogen to remove the excess of lead. A final filtration and evaporation yields the biuret in little granular crystals, which may be purified by recrystallisation. Biuret is very soluble in water and in alcohol, and may be detected by an intense red colouration when a few drops of a solution of a salt of copper, followed by a slight excess of potash, are added to its solution. It stands in the same relation to bicanate of ammonia, as urea does to cyanate of ammonia. Heated until it fuses, it is converted into cyanuric acid and ammonia.

BIVOUAC (written also BIHOUC, BIOUAC), is a term in military tactics probably derived from the German verb *bewachen*, or *beywachen*, signifying to watch over: it was originally applied to the strong parties of cavalry which were posted beyond the lines of entrenchment in order to watch the motions of the enemy, and prevent any attempt to take the army by surprise; and, because the soldiers thus employed passed the night in the open air, the term was subsequently used to denote the condition of any body of troops when in the field, and not regularly encamped under tents.

Formerly, no army served during a campaign without being well provided with every material necessary for its protection from the inclemency of the weather; but, during the wars of the Revolution, the French soldiers, except on a few occasions, dispensed with tents. At the periods in which military operations were suspended, they were quartered in towns and villages; and while on active service, they had only the occasional cover afforded by such buildings as happened to be situated in the district which they occupied. In all their great expeditions they remained *au bivouac*, as it was called; and the rapidity of their movements was due, in a great measure, to their freedom from the *impedimenta* with which armies were formerly encumbered. The important successes which so long attended the armies of France were,

no doubt, the cause of their example, in this respect, being followed by their opponents.

The carriage of an extensive tent equipage is necessarily attended with serious inconvenience on any change of position; but the removal of this evil must be accomplished, more or less, at the expense of the comfort and health of the soldier. During the summer season, and in the south of Europe, it may be indifferent whether or not the men pass the night under a roof; and indeed in those climates and in the summer season the open air may be preferred; but the cold winds and rains which are so frequently experienced in the spring and autumn in northern climates must induce painful and dangerous diseases, which render the men at an early period of their service unfit for the active duties of war. The French troops are now equipped with *tentes abris*; each tent, which is large enough to afford cover for two men lying down, consists of two pieces of canvas and two small poles, which are carried by the men strapped on to their knapsacks. On camping, these are soon set up, and the men, crawling into them to sleep, are protected from the dew and night-air.

Generally, in a bivouac, fires are kept up during the night with wood obtained from the neighbouring forests or villages: the arms being piled along the line, the troops place themselves in their rear in groups, each about its proper fire, which is lighted in any convenient situation, the men sitting or lying upon straw if it can be procured, and endeavouring to shelter themselves from wind or rain by means of boughs planted in the ground, or by boards formed into a roof, according to circumstances. The bivouac fires of an army often afford a means of arriving at an approximate estimate of its strength, by counting the number of fires, and allowing ten or twelve men to each. The bivouac of an army making a rapid retreat before an enemy is that in which the most disastrous consequences follow, both to the soldier and to the people of the country along the line of march; a complete disorganisation of the army too often takes place, and lamentable excesses are committed by men suffering the severest distresses from hunger and fatigue. The retreat of the French army from Moscow will be for ever remembered as an example exhibiting every species of misery which can be inflicted and suffered under the consequences of a rash and unfortunate expedition.

When a position is to be occupied for several days, it may happen that the men find means to construct rude huts for their protection with such materials as are at hand; and, in an extremely inclement season, they are usually cantoned in such towns or villages as are in their neighbourhood. They then light their fires in the streets, in gardens, or in barns; certain spots having been previously appointed as alarm posts, about which, on signals being given, the different corps may assemble, in order to form the line of battle, and act immediately as circumstances may require. Permanent cantonments for the winter are of this nature, and they are secured against surprise by outposts constantly maintained at proper distances about them.

BIXIN. ($C_{16}H_{13}O_2$). The red colouring principle of arnotto. It dissolves in alkaline solutions, and is again precipitated by acids as an orange powder. It is sparingly soluble in water, but easily so in alcohol and in ether. [ARNOTTO.]

BLACK. [LIGHT.]

BLACK ASH. [SODA ASH.]

BLACK ASSIZE, the name given to a fatal assize held in 1577 in the old town-hall of Oxford, situated at that time in the yard of the castle. Holinshed, Stow, and Baker make particular mention of it in their 'Chronicles'; but the best account of it is in Anthony à Wood's 'History and Antiquities of the University,' published by Gutch, 4to, Oxford, 1796, vol. ii. p. 188; where noticing the trial of one Rowland Jencks, a bookbinder, for sedition, he says: "The assizes therefore being come, which began the 4th of July, and continued two days after in the court-house at the castle-yard, the said Jencks was arraigned and condemned in the presence of a great number of people to lose his ears. Judgment being passed, and the prisoner taken away, there arose such an infectious damp or breath among the people, that many there present, to the apprehensions of most men, were then smothered, and others so deeply infected that they lived not many hours after. The persons that then died," he adds, "and were infected by the said damp, when sentence was passed, were, Sir Robert Bell, baron of the Exchequer; Sir Nicholas Barham, sergeant-at-law; Sir Robert d'Oyley, the high sheriff; Hart, his under sheriff; Sir William Babyngton, Robert d'Oyley, Wenman, Danvers, Fetiplace, and Harcourt, justices of the peace; Kerle, Greenwood, Nash, and Forster, gentlemen; besides most of the jury, with many others that died within a day or two after. Above 600 sickened in one night, as a physician of Oxford (Georg. Edrycus in 'Hypomnematis suis in aliquot libros Pauli Æginetæ,' edit. Lond. 1588, lib. 2) attested; and the day after, the infectious air being carried into the next villages, there sickened 100 more. The 15th, 16th, and 17th days of July sickened also above 300 persons, and within twelve days' space died 100 scholars, besides many citizens. The number of persons that died in five weeks' space—namely, from the 6th of July to the 12th of August (for no longer did this violent infection continue)—were 300 in Oxford, and 200 and odd in other places; so that the whole number that died in that time were 510 persons, of whom many bled till they expired. Some," Wood says, "left their beds, occasioned by the rage of their disease and pain, and would beat their keepers or nurses, and drive

them from their presence. Others ran about the streets and lanes in a state of phrenzy, and some even leaped headlong into deep waters. The physicians fled, not to avoid trouble," he says, "but to save themselves and theirs." The heads of houses and doctors almost all fled; and there was not a single college or hall but had some taken away by this infection. "The parties," Wood says, "that were taken away by this disease were troubled with a most vehement pain of the head and stomach, vexed with the phrenzy, deprived of their understanding, memory, sight, hearing, &c. The disease also increasing, they could neither eat nor sleep, nor would suffer any attendants to come near to them. At the time of their death they would be very strong and vigorous; but if they escaped it, then they were to the contrary. It spared no complexion or constitution, and the choleric it chiefly molested. That which is most to be admired is, that no women were taken away by it, or poor people, or such that administered physic, or any that came to visit. But as the physicians were ignorant of the causes, so also of the cures of this disease." Holinshed says that no child died of this infection. Baker says that Jencks was a bookseller, and was "questioned for speaking opprobrious words against the queen." He makes the deaths considerably below this statement, mentioning most of the eminent persons named by Wood, and "300 others, more or less." He also attributes it either "to the noisome smell of the prisoners, or from the damp of the ground."

It seems more than probable that the distemper which arose on this occasion, was a fever originating in the poisonous condition of the adjoining gaol, where the prisoners had been long close and nastily kept. Wood mentions a similar event at Cambridge, at the assizes held in the castle there in the time of Lent, 13 Henry VIII., A.D. 1521, where the justices, all the gentlemen, bailiffs, and most who resorted thither, took such an infection, that many of them died, and all almost that were present sickened, and narrowly escaped with their lives.

Father Sanders (in his book 'De Schismate Angl.' lib. iii.), noticing the black assize of Oxford, called it "ingens miraculum," and ascribed it as a just judgment on the cruelty of the judge for sentencing the bookbinder to lose his ears.

A contemporary account of the black assize is given in a letter from Sergeant Fleetwood, recorder of London, to Lord Burleigh, dated 30th July, 1577, printed in Ellis's 'Original Letters Illustrative of English History' (second series, vol. iii. p. 54); and another contemporary account, in Latin, from the Register of Merton College, was communicated to the Royal Society by Professor Ward in 1758, and is printed in the 'Philosophical Transactions' for that year, vol. l. part ii. p. 699.

(See also Holinshed's 'Chron.' vol. ii.; Stow's 'Annals'; and Pointer's 'Antiquities and Curiosities of Oxford,' 8vo, Lond., 1749.)

BLACK FLUX. A mixture of finely divided carbon with carbonate of potash. It is prepared by igniting bitartrate of potash (cream of tartar) mixed with half its weight of nitrate of potash, in a covered crucible until all volatile matter is expelled. As it is deliquescent it should be preserved in well stopped bottles. It is used for the reduction of metals on a small scale. [ARSENIC, DETECTION OF].

BLACK, or DOMINICAN, FRIARS, one of the four orders of mendicants whose founder was St. Dominic, a Spaniard, born at Calahorra, or Calaruega, a small town in the diocese of Osma, in Old Castile, about 1170. [DOMINIC, SAINT, BIOG. DIV.]

These friars were called Dominicans from their founder; Preaching Friars, from their office to preach and convert Jews and heretics (see 'Lit. Pat.' 8 Edw. I. m. 23; and 14 Edw. II. p. 1, m. 16); Black Friars from their garments; and, in France, Jacobins, from having their first house in that country in the Rue St. Jacques at Paris.

Their rule, which was chiefly that of St. Augustine, was approved by Pope Innocent III. in the Lateran Council, 1215, by word of mouth, and by a bull from Pope Honorius III. in 1216; but as they gathered power, even in Dominic's life-time, it was provided that the choice of the general of the order, as well as of the provincials, should vest in the order, and not depend on the pope, and that a general chapter should be held annually at Bologna and at Paris interchangeably. They were known, however, earlier than 1216; for Rymer in his 'Foedera,' tom. i. p. 137, has printed a licence or permission addressed from Pope Innocent III. to King John of England, in 1204, for such Dominicans and Franciscans, who might accompany the king in going beyond sea, to ride, the rules of their order obliging them to travel on foot.

Thirteen of these Dominican friars, according to Reyner ('Apostolat. Benedictin. in Angl.' tom. i. p. 161), including a superior, came into England in 1221, for the purpose of establishing their order in England; when Stephen Langton, then archbishop of Canterbury, giving his approval, they were allowed to settle, and fixed their first house at Oxford in that year. (Reyner, ut supr.; see also Wood's 'Hist. of Oxford,' p. 62; N. Trivet, 'Chron.' p. 176.) The Black Friars at London was their second house: originally placed near where Lincoln's Inn now stands, but removed about 1279 to some place near Castle Baynard, where the parochial district still bears the name of the order.

In 1232, after having had much contention with the Franciscans, the management of the Inquisition was deputed to the order by Pope Gregory IX., a weapon which was not allowed to rest idle in their hands, and which, under Torquemada and others, occasioned a fearful amount of suffering in the New World as well as

the Old. [INQUISITION.] The rule of the order forbidding them to hold any landed property was repealed in 1425 by Pope Martin V., and they very soon became one of the most richly endowed of all the orders. Chaucer, as well as other of the early English writers, have indulged themselves in satirising the excesses of the friars, without always distinguishing the order.

At the time of the dissolution of the monasteries under Henry VIII. there were fifty-eight houses of Dominicans in England and Wales. Tanner, who did not find them all out, reckoned the English houses only at forty-three.

Tanner says, "There were nuns also of this order, but I think none in England; for, though Thomas Lord Wake intended to have brought some of them hither, and had the king's licence for it, yet he seems not to have done it." ('Notit. Monast.' ut supr.) The nuns of Dartford in Kent, however, are believed to have been for some time of this order. King Edward III., in his letter to the Bishop of Rochester, concerning his intended foundation of that house, calls it "une Maison des soeres de l'Ordre de Precheurs." See Thorpe's 'Registum Roffense,' p. 312.)

Stevens has given an elaborate account of the origin of the Dominican order, from the 'Histoire des Ordres Monastiques,' already quoted, followed by a catalogue of the most celebrated men of English birth among the Black Friars who were writers. Amongst these, Robert Kilwarby, afterwards archbishop of Canterbury and a cardinal of the Roman Church, who died in 1280; Nicholas Trivet, the historian, who died in 1328; and Robert Holcot, who died in 1349, are the most distinguished. There were also many learned Dominican foreign writers, and the order produced many celebrated painters and sculptors. Among the painters may be especially mentioned Giovanni da Fiesole, called Fra Angelico, and Baccio della Porta, better known as Fra Bartolomeo.

BLACK JACK. [ZINC.]

BLACK LEAD. [CARBON; PLUMBAGO.]

BLACK-LEAD PENCILS. [PENCILS; PLUMBAGO.]

BLACK PIGMENTS. [CARBON; CHARCOAL, ANIMAL.]

BLACK ROD, USHER OF THE, is an officer of the House of Lords. He is styled the Gentleman Usher of the Black Rod, and is appointed by letters-patent. His deputy is styled the Yeoman Usher. They are the official messengers of the Lords; and either the Gentleman or the Yeoman Usher summons the Commons to the House of Lords, when the royal assent is given to bills. It is part of his duty to take into custody parties guilty of a breach of privilege or of a contempt, and he assists at the introduction of peers and other ceremonies. One of the officers of the Legislative Council of Nova Scotia is styled Gentleman Usher of the Black Rod.

BLADDER, DISEASES OF. The bladder, like every other organ of the body, is liable to inflammation. This disease is called *Cystitis*. When present there is pain and tenderness in the region of the bladder, also in the region of the perineum and sacrum, and along the urethra. The urine passed is clouded with mucus, and afterwards contains pus often mixed with blood. These local symptoms are accompanied with general fever. The inflammation may extend from the bladder to the peritoneum.

This disease may come on after the operations of lithotomy or lithotripsy, or other direct injury. It may be the result of specific inflammation of the urethra, extending to the bladder, or it may come on from irritating medicines acting on the bladder, as cantharides.

In its treatment antiphlogistic remedies of an active kind are needed, such as bleeding generally and locally, antimony, calomel, and opium. Opium should be given by the mouth and per anum for the purpose of relieving the pain. The bowels should be opened by enemata and gentle purgatives; and the recumbent position must be absolutely enjoined.

Cystitis may become chronic, or a chronic inflammation of the bladder may be produced by irritation in neighbouring organs, as in the urethra, rectum, or kidneys. There is pain in the bladder, frequent micturition, and mucus in the urine. The mucous membrane of the bladder may ulcerate, and the urine is mixed with blood and pus. The ulceration may extend through the bladder to the surrounding organs. In the treatment of this disease, the obvious cause must be removed. Opium for the pain, a generous diet, astringent infusions, as of buchu, and mineral acids, are principally recommended. Iron is sometimes of great use, also copaiba. Counter-irritation on the hypogastrium, or over the sacrum, should not be neglected. In very chronic cases it has been recommended to wash out the bladder with warm water by means of a double catheter. Lallemand recommends the direct application of the nitrate of silver.

Irritable Bladder.—A state of the bladder is recognised in which there is no inflammatory action, but in which the symptoms resemble those of cystitis. There is frequent micturition, uneasiness in and about the region of the bladder. The urine is mostly limpid and clear. This state depends on some derangement of the kidneys or general health, or it may come on from piles, stone in the bladder, or thread-worms.

In treating this state the great thing to be done is the removal of any observed cause. Where it comes on in a generally decayed state of the health, the treatment must be directed to this condition of the system.

Hæmaturia.—Blood in the urine may present itself when the

kidneys, bladder, or urethra are affected. When it arises from the kidneys the blood presents itself in the form of small tubular cysts, produced in the tubules of the kidneys. When the bladder is the seat of stone, cystitis, or malignant tumours, bloody urine makes its appearance. When the hæmorrhage proceeds from the urethra, the blood passes away independent of the urine. In these cases the cause of the hæmaturia must be treated.

Incontinence of Urine or Enuresis. This disease presents itself in two classes of cases, in children, and in adults. The first is a very common and troublesome disease. The urine is usually passed voluntarily during the day, but in the night it passes away involuntarily. Although frequently treated as though it were a bad habit, it is the result of a morbid state of the system, which must be removed, and the will should only be called into exercise to assist a judicious system of treatment. All causes of general debility should be removed. Sea air, cold sea-bathing, with the administration of iron, especially the tincture of the sesquichloride, are the most appropriate remedies for the want of tone of the nervous system which accompanies this disease. Strychnine has been recommended. The child should not lie on its back, and it should be awakened in the night, at stated intervals, to pass the urine voluntarily. Mechanical remedies are to be condemned.

In the incontinence of adults, either the urine passes away from previous retention, or, as happens in aged people, the bladder loses its tone, and both its expulsive and retentive powers are feeble or gone. In the first case the catheter must be employed to empty the bladder, and the retention treated. In the other case, tonics and other remedies necessary for the debilitated state of the system must be employed. Generally, however, little can be done, and cleanliness and the use of urinals are the only means left.

Retention of Urine. This arises from various causes, and the treatment must vary accordingly. The symptoms in all cases are, an inability to evacuate the urine, whilst the desire to do so is constant and frequently accompanied with pain, straining, and distress. The bladder is distinctly felt to be distended above the pubes, there is dullness on percussion there, and pressure produces great pain. Sick-ness is frequently present, the pulse becomes rapid, the skin hot, and at last symptoms of the absorption of the urine present themselves, and unless relieved, the patient dies from the blood becoming poisoned by the urea of the urine. All these symptoms are removed by the removal of the urine. This may frequently be done by the catheter, but the disease can only be cured by the removal of the cause.

The following are enumerated as causes of this disease. Stricture of the urethra. Inflammation of the urethra. Irritation and spasm of the neck of the bladder. Priapism. Abscess in the perineum. Abscess in the pelvis. Calculus in the urethra. Injury of the perineum. Paralysis. Diseased prostate. Blood in the bladder. Malignant disease of the bladder or urethra. Imperforate urethra. In each of these cases a special treatment is necessary, but in all it should be remembered that fatal results will occur unless the distended viscus is emptied of its contents. It often happens that for this purpose the catheter cannot be passed into the urethra; under these circumstances, the only means left is to puncture the bladder. This operation may be performed from the perineum, the rectum, and the pubes. In puncturing the bladder from the perineum, an operation is performed similar to that for lithotomy. [LITHOTOMY.] When this operation is deemed inadvisable, the bladder may be reached from the rectum and punctured here. It is only when these two methods are found to be impracticable, that puncturing the bladder through the parietes of the abdomen in the region of the pubes has had recourse to. These operations are not often performed: "but any one of them is much preferable at any time to postponement of relief, and consequent disaster by extravasation; and all, too, are preferable to pushing a metallic catheter by sheer force through an impassably strictured urethra." (Miller.)

Diseases of the Prostate. The prostate gland is liable to the various diseases of other parts of the urinary organ. It may be inflamed, or abscess may occur in it, or it may be subject to malignant disease. It is, however, most liable to enlargement or hypertrophy, which is one of the most troublesome and frequent diseases to which old age is liable.

Enlargement of the prostate is of two kinds. One is the result of inflammatory action, and the other is an enlargement independent of that process. The first is only temporary, and may be frequently speedily removed by treatment. It is the result of stricture, gleet, affection of the rectum, or injury to the perineum in riding. Leeches, purgatives, the recumbent position, and counter-irritants, are the proper treatment. The second form of enlarged prostate is more difficult to manage. It is one of the consequences of increasing age. The enlargement in these cases may be partial or general. One of the most painful consequences of either is a difficulty in passing the water. This comes on gradually, and is also attended with difficulty in emptying the rectum, as this organ is pressed on by the distended prostate. As the tumour enlarges, the calls to empty the bladder are more frequent, and the act is less perfectly accomplished, and a portion of residuary urine remains in the bladder behind the enlargement. Under these circumstances the bladder becomes irritable, and chronic cystitis is established. The symptoms of this disease are then added to those of the enlarged prostate.

There is no cure for this state of things, and the treatment is con-

sequently palliative. Much, however, may be done for the comfort of the patient. All excess and imprudence in diet and exercise must be avoided. The recumbent position must be maintained as much as possible. The bowels regulated by enemata and gentle aperients. Opium, iron, mineral acids, and buchu, may be given according to circumstances. In order to prevent distension, the catheter must be had recourse to, and the water drawn off occasionally.

BLADDERS, when brought to a clean and prepared state, are especially useful to druggists, oilmen, colourmen, and manufacturers, as coverings for various kinds of vessels. They derive their value from the thinness, toughness, and impermeability to water possessed by their substance. The bladders of the ox and other animals, when deprived of bits of loose membrane and other impurities, are washed in a weak solution of chloride of lime; they are then rinsed in clean water; then blown out, and submitted to pressure by rolling them under the arm, which stretches and enlarges them. They are finally blown out quite tight, fastened, and dried.

BLANK VERSE has been defined to be verse without rhymes, or the consonance of final syllables. Johnson, in his 'Dictionary,' says it means, "where the rhyme is blanded, or missed." But this, in the modern sense of blank verse, is far too indefinite, as it would include all unrhymed verse, such as Collins's 'Ode to Evening,' Southey's 'Thalaba,' and Longfellow's 'Hiawatha.' The term is now, and indeed has been from the beginning, used to distinguish the heroic line of ten syllables, without rhymes. All the verse of the ancient Greeks and Romans that has come down to us is unrhymed; but during the Middle Ages, rhyme, however it originated, came to be employed as a common ornament of poetical composition, both in Latin and in the vernacular tongues of most of the modern nations of Europe. In the 15th century, when a recurrence to classical models became the fashion, attempts were made in various languages to reject rhyme, as a relic of barbarism. Thus, Homer's 'Odyssey' was translated into Spanish blank verse by Gonsalvo Perez, the secretary of state to the Emperor Charles V., and afterwards to Philip II. Warton, in his 'History of English Poetry,' observes also that Felice Figliucci, in his admirable Italian commentary on the ethics of Aristotle, entitled 'Filosofia Morale sopra i libri dell' Ethica d' Aristotile,' not only de-claims against the barbarity of rhyme, and strongly recommends a total rejection of this Gothic ornament to his countrymen, but enforces his precept by his own example, and translates all Aristotle's quotations from Homer and Euripides into verse without rhyme. Figliucci's commentary was published in 1551. Warton afterwards observes: "In the year 1528 Trissino published his 'Italia Liberata di Goti,' or 'Italy Delivered from the Goths,' an heroic poem professedly written in imitation of the 'Iliad,' without either rhyme or the usual machineries of the Gothic romance. Trissino's design was to destroy the *terza rima* of Dante. We do not, however, find, whether it be from the facility with which the Italian tongue falls into rhyme, or that the best and established Italian poets wrote in the stanza, that these efforts to restore blank verse produced any lasting effects in the progress of the Italian poetry." This statement is allowed to stand uncorrected in the last edition of Warton; but in fact Trissino's poem was not published till it appeared in three volumes, the first printed at Rome in 1547, and the second and third at Venice in 1548. (See De Bure, 'Bibliographie Instructive,' iii. 678, 679.) The 'Italia Liberata' is stated by the biographers of Trissino to have been begun in 1525. Another work in blank verse by the same writer, however, his tragedy of 'Sophonisba,' celebrated as the first regular tragedy which appeared in the Italian language, was printed in 1524. (See the catalogue at the end of Riccoboni's 'Histoire du Théâtre Italien.') It was first represented at Rome in 1515. In 1516 the tragedy of 'Rosmunda,' also in blank verse, by Trissino's friend, Rucellai, was recited at Florence in the presence of Pope Leo X., and was printed at Sienna in 1525. In a work entitled an 'Historical Memoir on Italian Tragedy,' by Joseph Cooper Walker (4to. Lond. 1799), there is a short paper on the origin of blank verse in the Italian language (Appendix, No. 3, pp. xx.—xxiii.), in which the author observes that Trissino, though the first Italian writer who used blank verse in long works, and accordingly recognised both by his contemporaries and his countrymen generally as the first who introduced it into their poetry, is not, strictly speaking, to be considered as its inventor. Not to speak of the occasional specimens of blank verse which are to be found interspersed in the works of Boccaccio and his contemporaries, there is a blank verse poem called the 'Cantico del Sole,' written by St. Francis, the founder of the Franciscans, in the beginning of the 13th century. This poem, however, it seems, was thought to be in prose till its metrical character was detected by the critic Crescimbeni in his 'Istoria della Volgar Poesia,' a work published towards the end of the 17th century.

In the French language, in like manner, various writers have one after another attempted to write verse without rhyme. Among those who are said to have composed in this fashion are Jodelle and De Baif, who were two of the celebrated Pleiad of poets that adorned the age of Francis I. and Charles IX. (See Pasquier, 'Recherches sur la France,' liv. vii. chap. xii.; and Baillet, 'Jugemens des Savans,' tom. iv. pp. 94 and 124, edit. of 1725.) Afterwards Nicholas Rapin, who lived in the reign of Henry IV., repeated the same attempt, and, in the opinion of the Cardinal du Perron, with more success than De Baif. (See Baillet, tom. iv. p. 155.) Still more recently French blank verse was written

by De la Motte le Vayer, in the age of Louis XIV. None of these attempts, however, have had the effect of reconciling the French ear to this mode of composition, and it is probable that there is something adverse to it in the genius of the language.

The first English blank verse ever written appears to have been the Translation of the First and Fourth Books of the *Æneid*, by Lord Surrey, which was printed in 1557 under the title of 'The Fourth Booke of Virgill, intreating of the Loue between Æneas and Dido; translated into Englishe, and drawn into straunge metre,' Lond. without date, 4to, 1557, along with the second book, but which must have been written at least ten years before, for Surrey was executed in 1547. Surrey most probably borrowed the idea of this innovation from the Italians; but Dr. Nott is of opinion that he could not have seen Trissino's poem, already mentioned, as it was not printed till after his death, though written many years before. Ascham, in his 'School-master,' expressly commemorates this translation of Surrey's as the first attempt to write English verse without rhyme. "The noble Lord Thomas, earl of Surrey," he says, "first of all Englishmen, in translating the fourth booke of Virgil, and Gonzalvo Perez, that excellent learned man, and secretary to King Philip of Spain, in translating the Ulysses of Homer out of Greek into Spanish, have both by good judgment avoided the fault of rhyming." "The spying," he adds, "of this fault now is not the curiosity of English eyes, but even the good judgment also of the best that write in these days in Italy." The first who imitated Surrey in the new kind of verse which he had introduced was, according to Warton, Nicholas Grimoald, or Grimalde, some of whose poetical compositions were first printed in the same volume in which Surrey's translation from Virgil appeared. "To the style of blank verse exhibited by Surrey," says Warton, "he added new strength, elegance, and modulation. In the disposition and conduct of his cadences, he often approaches to the legitimate structure of the improved blank verse." The next thirty years may be said to have naturalised the new mode of versification in the language. The first theatrical piece which appeared in blank verse was Lord Sackville's tragedy of 'Gorboduc,' otherwise called the tragedy of 'Ferrex and Porrex,' which was acted in the hall of the Inner Temple in 1561, though not printed till 1565. Then followed George Gascoigne's tragedy of 'Jocasta,' which was acted at Gray's Inn in 1566. In 1576 the same author published a poem in blank verse, entitled 'Steel Glass.' In 1579 appeared George Peele's blank verse tragedy of 'David and Bethsabe.' In 1588 was published Aske's poem, in the same form of versification, entitled 'Elizabetha Triumphans.' 'A Tale of Two Swans,' a blank verse poem by William Vallans, appeared in 1590; and 'Hieronymo,' another tragedy without rhyme, had also been acted before that year. So that when Shakspeare began to write for the stage, as he is supposed to have done in 1591, he may be said to have found blank verse already familiar to the public ear as the legitimate form of dramatic poetry. (See Warton's 'History of English Poetry,' section xl, and the notes to the edition of 1824. See also section x. of the Dissertation by Dr. Nott on 'The State of English Poetry before the Sixteenth Century,' prefixed to his edition of Surrey's Poems, 1815.)

It is curious that Sir Philip Sidney does not mention blank verse in his treatise entitled 'The Defence of Poesy,' which must have been written after several of the pieces we have mentioned above had appeared. Sidney died in 1586, at the age of thirty-two. "Now of versifying," he says, "there are two sorts, the one *ancient*, the other *modern*: the *ancient* marked the quantity of each syllable, and according to that framed his verse; the *modern* observing only number, with some regard of the accent, the chief life of it standeth in that like sounding of the words which we call rhyme." "Truly," he afterwards adds, "the English, before any vulgar language I know, is fit for both sorts;" and then he goes on to show its superiority to the Dutch (that is, the German), the Spanish, the Italian, and the French, resting his argument entirely, in so far as the three last-mentioned tongues are concerned, on its alleged greater variety of final rhymes. In a preceding part of the treatise he expressly mentions the tragedy of 'Gorboduc,' making it an exception to the rudeness of all the English plays he had seen, as being "full of stately speeches and well-sounding phrases, climbing to the height of Seneca his style, and as full of notable morality, which it doth most delightfully teach, and so obtain the very end of poesy."

Notwithstanding the examples thus set, the employment of blank verse was almost confined to the drama for the greater part of the 17th century. Drayton, and Daniel, and Phineas Fletcher, and Davenant, all in that interval wrote long poems, and all in rhyme. Even dramatic composition had, after the Restoration, in the hands of Dryden and others, begun to revert to that form. Dryden, in his 'Essay on Dramatic Poetry,' published in 1663, discussed the relative advantages of blank verse (which he says the French call *prose mesurée*) and rhyme, giving the preference on the whole to rhyme; but he acknowledges that the majority of the public was in favour of blank verse, and adds, in his 'Epistle Dedicatory to the Rival Ladies,' that it is a measure "into which the English tongue so naturally slides, that in writing prose it is hardly to be avoided." At length in 1667 appeared the 'Paradise Lost,' and vindicated the capabilities of blank verse by the noblest exemplification of it the language yet possesses. In an advertisement prefixed to the second edition of this poem, printed in 1668, Milton, professing to give "a reason of that

which stumbleth many—why the poem rhymes not," says, "The measure is English heroic verse, without rhyme. . . . This neglect of rhyme is so little to be taken for a defect, though it may seem so perhaps to vulgar readers, that it is rather to be esteemed an example set, the first in English, of ancient liberty recovered to heroic poem from the troublesome and modern bondage of rhyming." He allows, however, and indeed urges the fact in vindication of himself, that "some both Italian and Spanish poets of prime note have rejected rhyme both in longer and shorter works, as have also long since our best English tragedies."

For nearly two centuries blank verse may be said to have been recognised as the only legitimate form for the higher species of dramatic composition in our language. "Aristotle observes," says Addison ('Spectator,' No. xxxix.), "that the Iambic verse in the Greek tongue was the most proper for tragedy, because at the same time that it lifted up the discourse from prose, it was that which approached nearer to it than any other kind of verse. For, says he, we may observe that men in ordinary discourse very often speak Iambics without taking notice of it. We may make the same observation of our English blank verse, which often enters into our common discourse, though we do not attend to it, and is such a due medium between rhyme and prose, that it seems wonderfully adapted to tragedy. I am therefore very much offended when I see a play in rhyme; which is as absurd in English, as a tragedy of hexameters would have been in Greek or Latin." Many long moral and descriptive poems, as well as shorter pieces of the same class, have also within this period been composed in blank verse; but here it can only be said to hold a divided empire with rhyme. The attempts that have been made to reject rhyme in our other measures have not removed the feeling in favour of rhyme, in so far as regards the establishment of the principle, however much the beauty of particular poems composed upon that system may have been admired. But some imitations of the classical poets in their own peculiar rhythms have great beauty, such as Milton's translation of Horace's Ode to Pyrrha, Longfellow's 'Evangeline,' in hexameters, and the unrhymed poems we have mentioned at the commencement; and also several successful translations, in hexameters and other unrhymed metres from the German, such as Göthe's 'Hermann und Dorothee,' and many of the lyrics. But these, as we have already said, are not included in what is now understood as blank verse.

The German probably, of all the languages of modern Europe, admits the greatest variety of unrhymed measures. From the practice of modern German poets, it would appear that any species of verse which may be used in that language with rhyme, may also be used without it. In the German translations from Greek and Roman poets we find every species of ancient metre successfully imitated, and of course without rhyme. That which approaches nearest to, or rather is identical with, our ten-syllable blank verse, is also much used, as in the following example:—

Der blinde Greis erhub sich alsobald,
Wählt' einen Text, erklärt' ihn, wandt' ihn an,
Ermahnte, warnte, strafte, tröstete,
So herzlich, dass die Thränen mildiglich
Ihm niederflossen in den grauen Bart.—KÖSEGARTEN.

According to Mr. Park, in a note to Warton's 'History of English Poetry,' vol. iv. p. 241, the poet Daniel, in his 'Apology for Rhyme,' published in 1603, appears to designate what we now call blank verse by the expression *single numbers*. The Italians call blank verse *verso sciolto*, that is, loosened or untrammelled verse.

BLANKET. [WOOLLEN AND WORSTED MANUFACTURE.]

BLANQUININ. An alkaloid, said to have been found by Dr. Mills in white cinchona bark (*Cinchona ovalifolia*). As its composition was not determined, its existence is very problematical. The substance found was probably *aricine*. [CINCHONA, ALKALOIDS OF.]

BLASPHEMY (in Greek *βλασφημία*, *blasphémia*), a crime marked for public punishment in the laws of most civilised nations, and which has been regarded of such enormity in many nations as to be punished with death. The word is Greek; but it has found its way into the English and several other modern languages, owing, it is supposed, to the want of native terms to express with precision and brevity the idea of which it is the representative.

Among the canonists, the definition of blasphemy is made to include the denying of God, or the asserting of anything to be God which is not God,—anything, indeed, in the words of the 'Summa Angelica,' voce "Blasfemia," which implies "quandam derogationem excellentis bonitatis alicujus et præcipue divinæ;" and this extended application of the term has been received in most Christian countries, and punishments more or less severe have been denounced against the crime. Modern jurisprudence, according to Herzog ('Real Encyclopädie'), defines blasphemy as whatever by word or action designedly dishonours the religion of the state. It is made a penal offence, except in Bavaria.

In our own country, by the common law, open blasphemy was punishable by fine and imprisonment, or other infamous corporal punishment. The kind of blasphemy which was thus cognisable, is described by Blackstone to be "denying the being or providence of God, contumelious reproaches of our Saviour Christ, profane scoffing at the Holy Scripture, or exposing it to contempt and ridicule."

('Commentaries,' b. iv. c. iv.) All these heads, except the first, seem to spring immediately from the root-sense of the word blasphemy, as they are that hurtful and insulting speech which the word denotes. Blackstone ('Comm.,' b. iv. c. iii.), speaking of offences against the Established Church, says the punishments were "not for *thinking* differently from the National Church, but for *railing* at that Church and obstructing its ordinances;" and we suspect, that whenever the common law was called into operation to punish persons guilty of the first of these forms of blasphemy, it was only when the denial was accompanied with opprobrious words or gestures, which seem to be essential to complete the true crime of blasphemy. Errors in opinion, even on points which are of the very essence and being of religion, were referred in England in early times to the ecclesiastics, as falling under the denomination of heretical opinions [HERESY], to be dealt with by them as other heresies were. There is nothing in the statute book under the word blasphemy till we come to the reign of King William III. In that reign an Act was passed, the title of which is "An Act for the more effectual suppressing of blasphemy and profaneness." It stated that, "Whereas, many persons have of late years openly avowed and published many blasphemous and infamous opinions contrary to the doctrines and principles of the Christian religion, greatly tending to the dishonour of Almighty God, and may prove destructive to the peace and welfare of this kingdom; wherefore, for the more effectual suppressing of the said detestable crimes, be it enacted, that if any person or persons having been educated in, or at any time having made profession of, the Christian religion within this realm, shall, by writing, printing, teaching, or advised speaking, deny any one of the persons of the Holy Trinity to be God, or shall assert or maintain that there are more gods than one, or shall deny the Christian religion to be true, or the Holy Scriptures of the Old and New Testament to be of divine authority," &c. These are the whole of the offences comprised in this Act. The penalties are severe: disqualifications; incapacity to act as executor or guardian, or to receive legacies; three years' imprisonment. (Stat. 9 Will. III. c. 35.) As to its main provision, this Act remains in force; but in 1813, the number of persons who openly avowed that they did not consider the doctrine of the Trinity as possessed of sufficient support from the words of Scripture when truly interpreted, to deserve assent, having greatly increased, and large congregations of them being found in most of the principal towns,—several clergymen also of undoubted respectability, learning, and piety having seceded from the Church on the ground that this doctrine as professed in the Church was without sufficient authority,—a Bill was introduced into Parliament to relieve such persons from the operation of this statute, and it passed without opposition. This Act, which is commonly called Mr. Smith's Act, after the name of the late Mr. William Smith, then member for the city of Norwich, by whom it was introduced, is stat. 53 George III. c. 160. The last prosecution for blasphemy was that of Mr. Moxon, in 1841, for issuing an edition of Mr. Shelley's 'Queen Mab.' The prosecutor was a person who had himself been convicted of libel, and he retorted by putting this almost obsolete law in action against Mr. Moxon, who was convicted, but whose sentence was merely nominal.

BLAST FURNACE. [FURNACE; IRON MANUFACTURE.]

BLASTING. The article MINING describes briefly the usual mode of removing masses of rock, in such engineering operations as relate to excavations. This mode consists in the insertion of gunpowder into a small opening bored in the rock or stone, and firing this powder by means of a train and a slow-match, or by a safety-fuse. The present article relates to the much more effective employment of electricity, as an agent for igniting the gunpowder. The change is not in the explosive material employed, but in the mode of igniting the material, and in the vast scale which this modification enables the engineer to adopt. To those who have only a slight acquaintance with the nature of galvanism, this igniting power is a great mystery; but it may be readily explained thus: So long as a galvanic current can travel along a wire uninterrupted, its progress is silent and harmless; but if the continuity of the wire be broken, or if anything occurs to interrupt the current for a small interval, intense heat and disruptive action take place at that spot, quite sufficient to ignite gunpowder if placed there. The arrangements therefore are such as to enable the wires of a galvanic battery to come nearly in contact at the place where the gunpowder is deposited for blasting.

Colonel (afterwards General) Pasley, after many useless attempts had been made to remove the sunken hull of the "Royal George" at Spithead, conceived that gunpowder might be carried down, by the aid of men descending in a diving-bell, and deposited in a water-tight vessel close to the ship, where it might be exploded by means of a galvanic current conducted by wires from an apparatus placed in another ship at some distance. The Admiralty having given the requisite permission in July, 1839, Colonel Pasley proceeded to form cylinders for containing the powder, and to provide electrical apparatus, boats of various kinds, a diving-bell, divers with water-tight dresses, and to make all the arrangements contingent on such a novel enterprise. The difficulties he met with were numerous, but he conquered them one by one; and at length, on September 23rd, he succeeded in exploding 2160 lbs. of powder, contained (under water) in a cylinder affixed to the outside of the hull of the sunken vessel. A second charge of 2300 lbs. was fired on October 15th. The effect of each explosion was

to shatter considerable portions of the ship, which portions were afterwards attached to chains and cables by divers who went down in diving-dresses, and then hauled up by men working at capstans above. The brass guns recovered by these means had a money value more than adequate to the whole cost of the operations; the wood recovered was chiefly placed in museums, or wrought up into articles of curiosity. Many different explosions, and a long series of auxiliary operations, were necessary to bring about this result.

The first application of the same agency to the blasting of rocks for engineering purposes was due to Captain Paris, an engineer at Boston, in the United States. Excavations were made in a rocky bed for the construction of quays and docks at that place; and the removal of the submarine rock was effected by galvanic blasting. The gunpowder was used in various quantities, from four to sixteen ounces, enclosed in air-tight tin canisters. The copper wires were inserted in the canisters; and these, as well as the powder, were secured by a waterproof composition. A hole was drilled in the rock for the reception of each canister, by a workman who descended in a diving-bell; and after securing the canister in the hole, and connecting all of them with a galvanic apparatus, a current exploded the gunpowder and blasted the rock. In the spring of 1842 the galvanic method was applied, under a modification introduced by Mr. Roberts, in blasting the rock of a quarry near the cathedral at Glasgow. In the same year some rocks were blasted under water, to aid in the reduction of a waterfall belonging to Lord Panmure, on the North Esk, with the view of rendering it accessible to salmon. In the autumn of the same year, the same agency was employed in making some excavations for the new harbour at Dunbar.

The experiment, however, which tested to the fullest extent the value of this system for engineering purposes was made by Mr. (afterwards Sir William) Cubitt, near Dover, in January 1843. The occasion for it thus arose: The six or seven miles intervening between Folkestone and Dover exhibit a continued series of bold cliff-works connected with the South-Eastern Railway; and it was on part of this course that the necessity occurred for a process of blasting on an unexampled scale of magnitude. Proceeding from Folkestone with these cliff-works, it was found that a bulky promontory, called the Round Down Cliff, stood directly in the way. It was first attempted to tunnel through this cliff; but the soil being unfavourable, the idea of removing the cliff at one blast by gunpowder occurred to Mr. Cubitt, the company's engineer. The arrangements for the explosion were thus made: A horizontal gallery was excavated through the cliff, extending for about one hundred yards parallel with the intended line of railway, in a direction nearly east and west. Cross-galleries were driven from the centre and extremes of this main gallery. At the end of each cross-gallery a shaft was sunk, having at its bottom an excavated chamber, eleven feet long, five feet high, and four and a half wide. In the eastern chamber was deposited about 5000 lbs. of gunpowder, in the western 6000 lbs., and in the central 7000 lbs., making about 18,000 lbs. in all, or more than eight tons. The gunpowder was packed in bags; these bags were placed in boxes; loose powder was sprinkled over the open mouths of the bags; and the bursting charges were placed in the centre of the main charges. The distance of the charges from the face of the cliff varied from about fifty to seventy feet. These being the underground arrangements, those for firing the charge were as follow: On the surface of the ground, behind the cliff, was a wooden shed for containing three galvanic batteries; each battery consisting of eighteen of Professor Daniell's cylinders, and two common batteries of twenty plates each. The wires from these batteries communicated at the other end by means of a very fine wire of platinum, the red-heating of which by the passage of the electric current would suffice to ignite the powder. The wires, covered with yarn, were extended on the grass to the top of the cliff, and then falling over the edge, were carried to the three excavated chambers, and placed in connexion with the charges. The wires were each about a thousand feet in length. All the passages and entrances to the powder-chambers were 'tamped,' or stopped up with dry mud, rammed down hard.

At two o'clock in the afternoon of the 26th of January, all the preparations being ready, three engineers worked the three batteries simultaneously; the three wires conducted the electric current to the three chambers, and the mighty explosion took place. Many persons expected that noise, smoke, and fragments hurled to a vast distance, would accompany the explosion; but such did not occur. The rock seemed almost as if it had exchanged its solid for a fluid nature, for it glided downwards into the sea in one body. Sir John Herschel, who was one among many scientific men present, in a communication to the 'Athenæum' shortly afterwards, says, "Of the noise accompanying the immediate explosion, I can only describe it as a low murmur, lasting hardly more than half a second, and so faint, that had a companion at my elbow been speaking in an ordinary tone of voice, I doubt not it would have passed unheeded. Nor was the fall of the cliff (nearly 400 feet in height, and of which no less than 400,000 cubic yards were, within an interval of time hardly exceeding ten seconds, distributed over the beach on an area of 18 acres, covered to an average depth of 14 feet, and in many parts from 30 to 50) accompanied with any considerable noise, certainly with none that attracted my own attention, or that of several others similarly stationed, with whom I afterwards compared notes."

The complete success of this experiment (by which it is said six months' time and 7000*l.* were saved to the company) naturally led to the adoption of similar means in other like cases. On March 2, in the same year, a second blast took place, a little beyond Round Down Cliff, on a smaller scale than the former, as the mass requiring removal was not so bulky; there were 7000 *lbs.* of gunpowder used, and 50,000 cubic yards of chalk dislodged. On April 18 a third blast took place, which consumed 10,000 *lbs.* of gunpowder. Later in the same year, in October, a fourth blast took place, in which the powder was distributed in twenty-eight distinct parts, deposited in as many separate excavations, and all intended to be exploded simultaneously; but from some disarrangement of the wires, several of the charges did not explode, and these were fired separately on the following day.

The success of these really grand operations naturally drew the attention of engineers, both civil and military, to this powerful agent; and during the subsequent period of sixteen years, the employment of the method has been very extensive. Mr. Brunel employed electro-blasting in the cliff-works connected with the South Devon Railway; Mr. Bidwell, in quarrying rocks near the Wrekin Hill, in Shropshire, made use of the same agency; as did Messrs. Kemp in disintegrating a large mass of stone at Rosyth Castle. A small application of the same system occurred at Black Gang Cliff, in the Isle of Wight; and a very large one at Seaford, on the Sussex coast. The construction of Portland Harbour of Refuge (now rapidly advancing) is greatly facilitated by the occasional employment of electro-blasting. The same may be said in reference to the great harbour-works at Holyhead. Indeed, civil engineers now regularly employ this process in their great works of tunneling and excavating through hard rock; while military engineers are equally ready to avail themselves of it for destroying bridges or defence-works, and naval engineers for blowing up sunken or wrecked ships. The system has been partially adopted in clearing the harbour of Sebastopol of the ships which the Russians purposely sunk there in the autumn of 1854.

In the professional papers of the Royal Military Engineers much valuable information is given regarding the best modes of blasting rock. In one paper, containing 'Instructions for blasting Rock in the Works of the River Shannon,' very exact rules are given, of which a few may here be briefly noticed: The charges of powder are not to be regulated so much by the depth of the hole to be bored as by the length of the line of least resistance, or the thickness of the rock to be blasted. Charges of powder, to produce similar proportionate results, ought to be as the cubes of the lines of least resistance. In the larger class of explosions advantage may usually be taken of fissures in the rock, to economise the amount of powder employed. The quantity of powder required to fill a hole one foot in depth varies as follows, according to the diameter of the hole:—

1 inch	5.028 ounces
1½ "	11.304 "
2 inches	20.112 "
2½ "	31.416 "
3 "	45.240 "

One pound of powder loosely poured, but not shaken, will occupy about 30 cubic inches: a cubic foot weighs about 57½ *lbs.* When a rock about to be blasted is stratified, and in close beds or seams, the holes should be bored in the direction of the strata; when unstratified, a tolerably exposed and even face should be prepared, and the holes bored parallel to that face. In small explosions, more powder is commonly used than is necessary: the best mode has been employed when the report of the explosion is trifling, and the mass lifted and thoroughly fractured without any projection of the stones. For tamping, the best material, as well for efficiency as for safety, is dried clay; the clay may be rolled into cylindrical pieces of two or three inches diameter, or any other convenient form, and dried at a smith's forge. After the charge and the wadding have been introduced into the hole, an inch or two of the tamping should be simply pressed down, the ramming being used only for the subsequent portion of the tamping; by this means fewer accidents will occur than by ramming down the whole of the tamping.

It may not be amiss here to describe an ingenious raft or float employed by Mr. Casebourne a few years ago in submarine blasting, on the works of the Hartlepool West Harbour and Docks. This raft was contrived in consequence of the clay or marl which formed the bed of the channel into the harbour being so hard, at a certain depth, that the ordinary dredging-machine was found to have little or no effect on it. The engineer, to overcome this difficulty, contrived a new apparatus. It consisted of a platform or raft, supported by four legs, on each of which was fastened a rack working into a pinion on the deck or platform, so that the latter could be raised or lowered at pleasure. The working level on the ebb tide was about eight feet above the level of the ground, in which position it remained for about five hours, or five and a half, until the tide flowed again. During this time two sets of boring-irons were in use, working through wooden boxes or tubes. These tools made holes in the clay four inches in diameter, and of the necessary depth for receiving a cartridge containing three or four pounds of powder, to which one of Bickford's fuses was attached, and the hole was then carefully tamped: and when the tide rose to the level of the platform the fuses were lighted, the raft

being floated away to some distance, to be out of danger when the explosion took place.

BLAZONRY, the art of delineating figures and devices in their proper colours or metals, on armorial shields: also used to express the hatching of the same, according to their different colours, by the engravers. The etymology of the word is somewhat uncertain, but Junius gives the English to *blaze abroad* as its origin, and he is probably right, for the Anglo-Saxon *blæs* has that meaning, and it has been used in that sense by modern English authors. Milton, in his paraphrase of Psalm cxxxvi., has—

Let us blaze his name abroad,
For of Gods he is the God.

The German *blasen* and the Anglo-Saxon *blæsan*, both meaning to blow or sound a horn or trumpet, may have contributed, as it was thus the attendants at a tournament announced the rank and dignities of the combatants. Mr. Lower, in his 'Curiosities of Heraldry,' says in a note that there are some who deduce it from the German *blasse*, a mark; a derivation we think wholly unfounded.

Allowing the mere invention to the Germans, says Dallaway, the splendid aid that heraldry receives from the art of blazonry is unquestionably the property of the French alone. Theirs are the arrangement and combination of tinctures and metals, the variety of figures effected by the geometrical positions of lines, the attitudes of animals, and the grotesque and almost inexplicable delineations of monsters. Dallaway, as well as other writers, considers that the tournaments held with such magnificence towards the end of the 10th century, under the auspices of Hugh Capet, were introductory of the more general usage and assumption of arms. (Compare Dallaway's *Inquiries into the Origin and Progress of the Science of Heraldry in England*; Gough's *Sepulchral Monuments of Great Britain*; Edmondson's *Heraldry*, pref.)

BLEACHING is the process by which certain animal and vegetable products, and especially such as are used as articles of clothing, are rendered white. The principal substances of the animal kingdom which are subjected to the operation of bleaching are wool and silk; those of vegetable origin are chiefly cotton and flax. These bodies contain a quantity of colouring matter, which though natural to them is not an essential constituent; it appears also that the colouring matter is more readily acted upon by chemical agents, and suffers decomposition with greater facility, than the animal and vegetable matters with which it is mixed. On these accounts it is removed by operations producing little or no injurious effect upon the texture or durability of the articles from which it is separated; and thus not only is their beauty increased, but they are fitted for the reception of the colours of the dyer and the ornamental designs of the calico-printer.

The process of bleaching is one of unquestionable antiquity, and more especially in Egypt, where white linen was used as clothing. Of the Egyptian processes nothing is known with certainty; they were probably tedious and imperfect; consisting perhaps of little more than exposure to air, light, and moisture. (See Plin. xix. 1, on flax.)

Down to the reign of George II. the art of bleaching was scarcely known in Great Britain; it being usual to send the brown linen manufactured in Scotland to Holland to be bleached. The Dutch method consisted in steeping the linen for several days in a solution of potash, which was poured upon it boiling hot; the cloth was then removed, washed, and afterwards put into wooden vessels containing butter-milk, for nearly a week. This operation being over, the cloth was spread upon grass, and exposed to light, air, and moisture for some months; the cloth sent from Scotland to Holland was generally kept there for half a year. One of the earliest improvements made in this tedious process was proposed by Dr. Home of Edinburgh, who introduced the use of water acidulated with sulphuric acid, instead of the sour milk previously employed: by this substitution a great saving, especially of time, was effected, for the sulphuric acid was as effectual in one day's application, as the sour milk in six or eight weeks.

Until the year 1787 little further alteration was made in the process of bleaching. But a most important improvement was effected in it in consequence of the discovery by Scheele, a celebrated Swedish chemist, of what he termed dephlogisticated marine acid, about the year 1774; this substance was afterwards called oxymuriatic acid, but is now known by the name of chlorine gas. The property which this gas and its solution in water possess of destroying vegetable colours, suggested to Berthollet the idea that it might be advantageously employed in bleaching, and might essentially shorten the process. In the year 1785 he read a paper before the Academy of Sciences at Paris, which was published in the 'Journal de Physique' of the same year. In this paper he mentioned that he had tried this gas in bleaching cloths, with a perfectly successful result: in the following year he published another paper on the subject, and showed the experiment to Mr. Watt, who first introduced this method of bleaching practically into England. About the same time Mr. Thomas Henry of Manchester was actively engaged on the same subject. Indeed, these gentlemen appear to have unreservedly described to each other the progress of their experiments: and to them belongs the chief merit of introducing the new mode into the neighbourhood of Glasgow, and into Lancashire. By the application of this method, as much bleaching is as well performed in a few hours, and in a space of a hundred yards square, as

on the old process would have occupied weeks of exposure upon a hundred acres of land.

Chlorine was first used in the state of simple solution in water; afterwards, in order to lessen its destructive action when used in too concentrated a state, it was proposed to add potash to it. This compound however was not found to answer the purpose; but in the year 1798, Mr. Tennant of Glasgow took out a patent for a liquid compound of chlorine and lime. This patent being set aside, he took out another for impregnating dry hydrate of lime with chlorine gas; this invention was not contested, and the chloride of lime, generally known by the name of bleaching-powder, is now almost universally employed, especially in the bleaching of cotton: it is a compound which answers the purpose with economy, celerity, and safety.

The colouring matter of cotton, flax, and hemp, is insoluble in water, and appears to be of a resinous nature: it is partially dissolved by heated solutions of lime and potash, or soda; and by their use, and the application of a solution of bleaching-powder and dilute sulphuric acid, the colouring matter which is not dissolved is destroyed. Cotton is more readily bleached than flax or hemp, and these more readily than wool: indeed this last-mentioned substance, as well as silk, is generally bleached by the fumes of burning sulphur, or sulphurous acid gas, after they have been properly cleansed. Straw and feathers are also bleached by sulphurous acid gas. Wax is generally deprived of its colour by mere exposure to air, light, and moisture.

The bleach-works of Lancashire and Glasgow are among the largest and finest of our manufacturing establishments; exhibiting mechanical contrivance, chemical knowledge, and those powers of combination and classification so remarkably developed where many hundred persons are employed in one establishment. The following is an outline of the series of processes, as conducted on a large scale: Supposing ordinary cotton-cloth or calico is about to be bleached, the 'pieces,' as they are called, usually of twenty-eight yards each, are sewn or tacked together into a web six or eight miles in length; which web, connected at the two ends, becomes practically endless, like the travelling-web of a printing machine, or the wire-web of a paper-making machine. This web is passed over a heated cylinder, to singe off the loose fibres; it is then washed to remove the flax or dressing; it is next exposed for eight or ten hours to a hot solution of lime; and is again washed to remove the lime which may adhere to the fibres. The long web of cloth is then steeped in water containing a little sulphuric acid; after which it is washed a third time in clear water. Three of these long webs, making twenty-four miles in length of calico, are boiled in a solution of soda, then washed, then passed through a weak solution of bleaching-powder, and then allowed to remain in a heap for the chloride to act on the fibres. Next come, in succession, a second dip into dilute acid, a fifth washing, a second application of soda, a sixth washing, a second application of bleaching-solution, a third dip in the acid, and a seventh washing—thus showing, in a striking degree, how complex are the processes which modern ingenuity enables the manufacturers to carry on at a very cheap rate. The bleached calico is washed in hot water, and squeezed between rollers; the web is separated into its component pieces; and each piece is folded and dried. It may be remarked that the bleaching of other kinds of cotton goods, and of yarn and thread, although involving minor peculiarities, may be understood from this description of the bleaching of calico and of cotton for printed dresses.

Not a year elapses without developing some new processes or apparatus for bleaching; many of these novelties are made the subjects of patents, though not always with advantage to the patentees. One patent, by M. David, of Paris, relates to a peculiar mode of applying chlorine to the goods to be bleached. The chemical materials for making the gas are to be provided by the bleacher; and as the gas is generated, it is conveyed by pipes into a close chamber. The woven goods are to be laid on perforated shelves in this chamber, and thus be acted upon by the chlorine. A fan or blowing-machine is used to clear the chamber of gas before the goods are removed from it; and glass windows are provided to the chamber, through which the process may be watched. A second patent relates to a peculiar way of conducting the cloth into and through a vessel of liquid, and beating it on both surfaces immediately after its immersion, in order that the fibres may become impregnated and the superfluous liquid be driven off. Another patent is for a peculiar mode of causing the woven goods to pass over two rollers, one above the other, in a close chamber filled with chlorine or sulphurous acid gas. Passing over many inventions of varied character, we may advert to a dash-wheel invented by Mr. Wallace of Glasgow, and brought largely into use in 1857. The dash-wheel, generally used by bleachers, dyers, and calico-printers, is a hollow cylinder or box, made to rotate with great rapidity, so as to wash very speedily any woven goods immersed in water within it. Now Mr. Wallace's plan is to render the dash-wheel more extensively available than heretofore as a bleaching and cleansing apparatus. The wheel is mounted on a hollow shaft, by which it is put in communication with a steam-pipe. Steam, instead of water, is admitted through perforations in the shaft, into the several compartments into which the interior of the wheel is subdivided. Acids, alkalies, or soaps may be placed in cisterns above the wheel, in solution with water; and may be made to descend through pipes into the hollow shaft. By this means, any admixture or variety of chemical agents, whether for washing or for bleaching, may

be admitted into the wheel, and made to act upon the woven cotton goods placed in the several compartments. The liquid, when the washing or bleaching is effected, finds egress by holes in the circumference of the wheel. A dash-wheel of six feet diameter, on this construction, is estimated to make twenty-four revolutions per minute; one of nine feet diameter, sixteen revolutions—the velocity of the circumference being in each case about four hundred and thirty feet per minute. A steam-engine of about five-horse power, with steam of three or four pounds per inch above atmospheric pressure, would produce this degree of revolving action.

With respect to the theory of bleaching it may be observed, that the action of lime and the alkalies, potash and soda, appears to be that of mere solvents; they probably dissolve the colouring matter without effecting much alteration in its properties. The actions of atmospheric air and chlorine seem to be similar to each other, and very different from that of lime and the alkalies. The oxygen of the air aided by the action of light and moisture apparently combines with and destroys the colouring matter; while the chlorine, decomposing the water which is present, forms muriatic acid with the hydrogen of the water; another portion with its oxygen probably giving rise to a compound of easy decomposition, the nascent oxygen of which acting like that of the air, though more powerfully, produces the same oxidising effect upon the colouring matter, but more perfectly, and in a much shorter period. That water is necessary to the action of chlorine upon vegetable colouring matter, is shown by immersing dry colouring matter in the dry gas, in which case no decoloration whatever is effected, but it ensues immediately on the introduction of water. The bleaching of rags for paper-making is effected by the agency of chlorine. Paper also, when written on or printed, may be bleached by the same means. There are some operations in which the removal of colour is hardly referable to the process of bleaching; such for example as the decoloration of sugar, which derives its colour, not from any natural cause, but the partial decomposition effected by heat. This is removed by what is usually termed animal-charcoal or ivory-black; which powerful decolorant is also used in some chemical operations for the same purpose.

We must now notice the proceedings connected with bleach-works regarded as *factories*, subject to legislative control.

An opinion has during several years prevailed among many persons conversant with the manufacturing establishments of the North, that when spinning and weaving mills were placed under the operation of the Factory Act, in relation to the employment of women and children, bleach-works ought to have been included, as well as print-works and dye-works. The manufacturers, on the other hand, have all along contended that there was no need for such an extension. The attention of Parliament having often been called to this subject by the upholders of the Factory Act, at length, in 1854, the Government appointed a commission—"To inquire how far it may be desirable to extend the provisions of the Acts for the better regulation of Mills and Factories to bleaching works;" and Mr. Seymour Tremenheere, one of the factory inspectors, was appointed commissioner. The commissioner presented his report in June 1855. It is necessary to mention that this inquiry arose out of a movement which was marked by much collision of opinion. Early in 1854 the Earl of Shaftesbury brought into the House of Lords an "Operative Bleachers Short Time Bill," intended to restrict the labour of females and young persons in bleach- and dye-works to ten hours and a half per day. He was supported in this by the operatives themselves. There was also a petition sent to Parliament signed exclusively by members of the clerical and medical professions, 128 in number, all resident in or near Manchester. The petition declared that females and young persons often worked from fourteen to twenty hours a day in bleach- and dye-works, and sometimes for days and nights consecutively without intermission, except for meals; and they insisted that nothing but legislative interference could remedy the evil. The master bleachers contested these statements, in a memorial addressed to Lord Palmerston. They did not, it is true, deny that the hours of work were sometimes very long; but they asserted that this was a necessary condition of certain peculiarities in the trade. "The trade of bleaching and finishing is difficult to manage; and it differs from other branches of the cotton trade in this—that the supply of goods to be bleached fluctuates. During some portions of the year we are only partially employed, whilst at other times we have more work to do than could be accomplished if the hours of labour were restricted." They declared that the greatest care, industry, and skill are required to enable English bleachers and dyers to compete with those of the continent and of America; and that any legislative enactment which increased the working expenses would be disastrous to the bleachers, who had no less than two millions sterling of capital sunk in the trade. The Earl of Shaftesbury's Bill, though passed by the Lords, was checked in its progress through the Commons by the lateness of the session; but the discussions in both Houses led to the appointment of the commission above adverted to.

Mr. Tremenheere, after visiting most of the principal bleach works in the United Kingdom, classified the processes into three groups—preparing, bleaching, and finishing. The preparing includes the marking with the needle the pieces of cloth with the initials or private mark of the owner; sewing or pasting the ends of several pieces together, to facilitate the subsequent processes; and dressing or

singeing the cloth by means of hot plates or jets of gas. The bleaching comprises all the processes of a chemical nature. The finishing includes mangling, drying, calendering, hooking, folding, making-up, labelling, and packing. Where the dyeing is effected by the bleacher (which is often the case) it is included among the processes of "finishing." At a large bleaching establishment near Bolton, Mr. Tremenhare found the designations of work people to be more than twenty in number: the loaders, banders, dressers, bowkers, crofters, wheelers, tubbers, baggers, white-washers, squeezers, white-manglers, dyed-manglers, rawers, stovers, pelters, calenderers, makers-up, calico-packers, shirting-packers, beetlers, chest-manglers, canroyers, dyers, black-dyers, stitchers. Mr. Tremenhare appears to have been unable to ascertain the total number of hands engaged in this trade. The largest firms mentioned by him are Messrs. Ainsworth's, Messrs. Ridgway's, and Messrs. Hardcastle's, all in the Bolton and Bury district, and employing respectively 508, 461, and 440 hands at the time of the inquiry. Concerning the long hours of work, there was no doubt, Mr. Tremenhare said—"Some masters will have so much employment as to keep their hands employed for twelve months together from between six and seven in the morning until eight, nine, or ten at night; and a portion of their hands will occasionally work on to a later time, and sometimes nearly all night, for two or three nights together. The evidence shows that both at the large and small bleaching and finishing works a very common state of things is that the work goes on for these 'long hours' (as they are called) continuously for months together; in some instances, for so many as six months, in others for twelve months or more." On a review of all the observations made and evidence taken, Mr. Tremenhare arrived at an opinion that the hours of labour for women and young persons in bleach works ought to be limited by legislative enactment—admitting, at the same time, that the working expenses would be increased thereby.

Towards the close of 1855, another bill was brought into the House of Commons, to carry out the commissioner's recommendations; but this, partly owing to the advanced state of the session, and partly to the opposition raised, was thrown out on the second reading. In 1856 a further attempt was made, but was defeated by a still larger majority than in the preceding year. In 1857, owing to doubts expressed concerning the correctness of Mr. Tremenhare's statements and deductions, the House of Commons appointed a committee "To inquire into the circumstances connected with the employment of women and children in the bleaching and dyeing establishments in England, Scotland, and Ireland; and to consider how far it may be necessary or expedient to extend to those establishments provisions regulating such employments." The committee presented one report on the 5th of July, and another on the 28th—simply announcing that the inquiry was not completed, and recommending the re-appointment of the committee in the next session, 1858. The master bleachers examined by the committee declared, as with one voice, that the hours of working cannot be made regular; the orders come to them irregularly, and must be attended to whenever and as soon as they come. The nature of the market is such as to give generally two very long seasons in the year to the bleachers, in spring and autumn, with intervening periods of greater leisure; and the bleachers assigned reasons why it is better to vary the hours of work than the number of hands. During the session of 1858, the attention of parliament was too much absorbed by other subjects to attend to the one in question; and down to the present time (May 1859) bleach works remain free from the operations of the Factory Act, or of any statute limiting the employment of women and children.

For certain particulars further illustrating the subject of the present article, see BANDANAS; CALENDERING; CALICO-PRINTING; DYEING; FACTORIES, and FACTORY ACTS.

BLEEDING, the operation by which blood is removed from the body, with a view to the prevention and cure of disease. Bleeding is either general or local. General bleeding is practised when the object is to lessen the whole mass of the circulating blood; local, when the object is to lessen the quantity in some particular part of the body. General bleeding consists either in opening a vein (venesection), or in opening an artery (arteriotomy). Venesection, the most common mode of abstracting blood, is a simple operation, and in skilful hands neat, elegant, and safe; but in unskilful hands dirty, bungling, and exceedingly unsafe: it is always performed with a lancet. Various means are employed for the removal of blood from particular parts of the body, such as cupping-glasses, the scarificator, the division of visibly distended vessels with a lancet, and leeches. The mode of performing the operation of venesection and arteriotomy is fully detailed in the common books on surgery, where the requisite precautions are pointed out. It is only necessary to add here, in reference to local bleeding, and more especially to the application of leeches, that when there is a difficulty in making leeches fix readily on any particular part, they may often be made to do so at once, by first cooling the part with a cloth dipped in cold water, or by moistening it with cream or milk, or a single drop of porter, and then confining the leeches in the proper situation under a small glass. It should be borne in mind that these animals are cold-blooded, that heat is highly injurious to them, and that handling them with the warm hand, or keeping them long out of water in a heated room, totally unfits them for the performance of their office. Great fatigue to the patient, great aggravation of his

disease, and even the loss of life itself, sometimes result from the ignorant and unskilful manner in which attempts are made to apply leeches. In the diseases of infants and children especially, in which general bleeding can rarely be employed, the preservation of life constantly depends on the efficient application of leeches.

It is scarcely one time in a hundred that the physician finds a single person in a family who has the slightest notion of the proper mode of performing this service to the sick. It would be wonderful indeed were it otherwise, when the education of women, in reference to the entire class of subjects the knowledge of which is necessary to qualify them for the performance of their duties as nurses and as mothers, is universally and wholly neglected.

The conditions of the system which require the abstraction of blood, and the benefit which the removal of it is capable of effecting, will be better understood after reading the account of the blood. [BLOOD, NAT. HIST. DIV.]

BLENDE. (ZnS.) The natural sulphide of zinc, constituting an important ore of that metal. [ZINC, SULPHIDE OF.]

BLIGHT, a popular name for any kind of pestilence which affects cultivated plants by curling up or destroying their leaves and blossoms, or by giving them a yellow sickly appearance, or by covering certain parts of them with unnatural colours. Dr. Lindley thus describes the popular idea which the word under various circumstances is used to express. "Blight is a sunstroke or frostbite, a plague of insects or of fungi, a paralysis of the roots, a gust of bad air; it is wetness, it is dryness, it is heat, it is cold, it is plethora, it is starvation, in short it is anything that disfigures or destroys the foliage." To a term thus loosely applied no precise meaning can be assigned; for the effects to which it relates are produced by causes of totally different kinds. The attacks of insects, especially of the aphids, produce a curling in leaves, and a stoppage of growth; caterpillars spread their nets from branch to branch, destroying all they meet with; cold dry winds in the spring, or sharp night frosts at the same period, cause an appearance of scorching; and finally the ravages of numerous parasitical fungi, some of which are superficial and others intestinal, are the origin of much that is popularly called blight. The attacks of insects form a subject which it is the business of the entomologist to explain. Blight from the attacks of parasitical fungi will be explained under the head of MILDEW; that which is produced by meteorological influences may find a brief notice in this place.

Nothing can be more absurd than the explanations of this malady as given by many writers on gardening, nor anything more simple than it is in reality. One person talks gravely of its being caused by certain transparent flying vapours, which may sometimes take such a form as to converge the sun's rays like a burning-glass. The fact appears to be this: when a plant first produces its young branches and leaves, all the new-born parts are tender and succulent, and part with their fluid matter with rapidity until the solidification of the recently-created tissue has taken place. To enable this function to be performed regularly and without interruption, it is necessary, 1. that the air should be in a certain state of humidity, or the perspiring parts will lose their aqueous particles too fast; and, 2. that the temperature should not be low enough to destroy the vitality of the tissue. Suppose these conditions to be maintained without interruption, leaves and branches gradually become fully formed, and no blight appears; but if, as frequently happens in this country, the air is rendered extremely dry by the prevalence of easterly winds, the young parts perspire with such rapidity that the loss thus occasioned cannot be made good by the roots, and the consequence is that the tissue becomes dried up and scorched as it were, or at all events is brought into a more or less diseased condition. Such is blight properly so called, if that term can be considered applicable to any particular form of disease. It will be obvious that the only remedy for this, after it has occurred, will be the restoration of the atmosphere to the necessary state of humidity, or to a sufficiently equable temperature. For this, artificial means can only be employed upon a limited scale, and perhaps the only practice which is ever attended with much advantage is frequently washing the blighted plants with a syringe. It has by some been recommended that wet litter should be burned to the windward of large tracts covered with blighted plants, and it has been supposed that the smoke thus produced will remedy it by destroying insects, its imaginary cause; but if any effect is ever obtained from such a practice, it is not by the destruction of insects, but by the interposition of a canopy of smoke at night between the plants and the sky, by which radiation is stopped, and the severity of the cold diminished.

Blight is often used to designate the mischief done by those insects which are destructive to vegetation; and consequently many insects of various genera and even orders must be included under this common denomination; but it is not our intention, however, to describe the habits of all these various species, as they will be found under their respective heads in NAT. HIST. DIV.

The aphides, or plant lice, especially, are great pests to the gardener. [APHIDS, NAT. HIST. DIV.] It may be observed, however, that as each infested plant has its peculiar aphid, and as the aphides are quite as numerous (if not more so) when the plants are covered with a glass as when they are exposed, it is absurd to imagine that blight is bred in the air (the vulgar notion), and brought to these plants by the wind. Certain winds may be more favourable than others for hatching the

it was in use some years before the Society of Arts arrived at its decision, and that its claims were very ably advocated by the late Rev. Dr. Carpenter, LL.D., of Bristol, whose letter addressed to the society, contains many valuable suggestions on printing for the blind. Mr. Lucas has himself stated that the 'Penny Cyclopaedia' contained a fair exposition of his principles, which we are glad to reproduce:—"The characters are employed for reading, writing, arithmetic, and music; and they are so simple, that to any book for the blind, not more than half the number of types are required that are necessary to print the same for those who are blessed with sight. Should the event prove as successful as is intimated in the above announcement, and so great a barrier to the improvement of the blind be removed, it will be desirable that the different institutions should unite their exertions, and set apart a common fund to supply their pupils, as well as other blind persons, with so powerful an auxiliary to their progress in knowledge. The alphabet is composed of thirteen simple characters, and thirteen formed from the roots of these with a crotchet-head to each. There are ten double letters from the same roots, distinguished also by the crotchet-head: these also represent the nine figures and the cypher, whether used as numerals or ordinals. In all thirty-six characters are employed. The advantages attending the use of stenographic characters seem to be in the saving of types, paper, and labour, thus materially diminishing the cost of books for the blind. The disadvantages attending the system we are speaking of appear to consist chiefly in the confusion which the learner must feel in having but one character employed in several offices, as in the double letters, numerals, and ordinals, and in the necessity that every person should be a stenographer who communicates with the blind by writing. These difficulties are not very great for persons to overcome who have never been accustomed to a written language.

"The manner in which the characters of Mr. Lucas are employed may be seen in the following commencement of St. John's Gospel, only that we give the extract in Roman letters instead of using the stenographic characters.

t gospl b st jon, chap: 1.

in t bgini ws t wrd a t w ws w g, a t w ws g. t sam ws n t bgini w g. I thins wr mad b hm, a wo hm ws nt athin mad tht ws mad. in hm ws lif a t l ws t lit f mn.

"It will be observed that the repetition of numerous letters is avoided; particles are represented in most instances by their initial letter, and when a word, having been once mentioned, recurs immediately, or frequently, it is represented by its initial letter also."

An undoubted defect in Lucas's system is the confusion which must arise from having double letters and figures, whether cardinal or ordinal, represented by the same stenographic signs; thus the signs for th, ch, and ll also represent 471. The contractions are very numerous, many words are expressed by a single character, and other words are contracted by the omission both of vowels and consonants. The value of full spelling is great, especially to the young blind; those who have already learned to read while possessing sight, would, in time, get over the difficulties the system presents.

The next system which came into use in point of time was Frere's, also stenographic, founded on Gurney's shorthand, as Lucas's was on Byrom's. This system is phonetic, and is formed on the "combination of elementary sounds." It professes to be composed of twenty-nine signs, to be extremely simple, and to have only four descriptions of signs, which represent thirty-two different sounds. Its distinctive principle, compared with Lucas's, is the phonetic one, the powers or vocal sounds of the letters rather than their name-sounds being taught, "each word being embossed according to its actual pronunciation, the names of the characters combined, or sounded together, give the word." The 'Memoria Technica' which accompanies the lessons is most burdensome, and the twelve rules in verse for supplying the omitted vowels could never be regarded by blind or other readers who had to commit them to memory, in any light but as a distasteful task. We learn, however, that their employment is optional, though the

system would be incomplete without them! The twelfth of these rules is:—

"Whene'er the proper rule don't yield you satisfaction,
On trial you will find the word is a contraction."

"A fair knowledge of the system may be acquired by those who have sight in three or four hours." Two things are noteworthy in this agreeable announcement. 1. That a system of stenographic reading can be acquired in three or four hours. 2. That stenographic systems require ordinary readers to learn them before they can assist their blind brethren in the acquisition of the art of reading.

The last system to be described is Moon's; although it is not stenographic in one sense, its characters have sufficiently the appearance of stenography to be taken as such; and again, although it claims to be the common alphabet simplified, it is certainly arbitrary enough for a first observer to recognise no similarity between it and the forms to which he has been accustomed. Mr. Moon, like Mr. Frere, is himself a blind man, and he has laboured hard to establish a system which he believes is destined to supersede all others. If all that he says in its favour could be taken for granted, no further question could arise as to the best alphabet for the blind. The judgment and experience of those who have means and opportunities for deciding, at least equal to Mr. Moon's, but whose zeal, enthusiasm, and interest are not fettered by partial views, do not bear out his statements.

"Moon's system is adapted to the cottage, because anybody can teach it." This statement is more than questionable. Anybody of moderate intelligence can doubtless acquire it if they can already read. The same may be said of Alston's books, and herein consists their superiority—anyone who can read may at once be a teacher of reading to the blind. "It is adapted to the dull finger of the labourer, because it is very plain to the touch." This is no exclusive advantage in Moon's letters. "It is suited to the aged, the sick, and the ignorant, because it is so easy to be understood." This is a benefit compared with Lucas's and Frere's, but in this respect Alston's is certainly more deserving of praise. "The words are spelt at full length," and "full spelling is essential to accuracy." Granted, so are Alston's, which system does not employ even the few contractions Moon introduces; in this respect Moon's books are superior to Frere's or Lucas's, but inferior to Alston's. Moon's alphabet consists of "the common letters simplified, and therefore is easily learnt and taught by all who know their a b c." But, Alston's consists of the common letters themselves. We have doubts about the easy recognition of the transformed letters, though none as to the increased tactile power of the new forms in comparison with the certainly more intricate forms of the ordinary alphabet. "Six of the Roman letters are retained unaltered; twelve others have parts left out so as to be left open to the touch, and yet be easily remembered as half of a well-known letter." Of these twelve none would be recognised from any similarity they bear to the letter they represent; they must therefore be regarded as arbitrary characters. "Five or six new and very simple forms complete the alphabet." These are arbitrary; so that this system of the "common letters simplified" is in fact composed of six of the Roman letters unaltered and eighteen arbitrary characters. Most certainly Moon's alphabet does not possess the superiorities over others to which it lays claim. That it is a good arbitrary character for the blind no one who has paid the least attention to the subject can deny. The question, however, has yet to be settled whether an arbitrary or an alphabetical character is the best for the blind. And on this point evidence must be adduced.

We find the schools for the blind in London, Glasgow, Newcastle, Manchester, and York, use the books in Alston's Roman characters; those of Bristol and Belfast also use these books, and in addition some printed at Bristol with lower-case letters as well as capitals. (Several of the parties competent to form a judgment on the matter, advocate the use of capitals.) We find Lucas's stenographic system in use at Bath, where the defective orthography is considered objectionable for young readers; the Roman alphabet has also been used in some cases; while for adults generally Moon's system is considered the best. At the Nottingham school, Lucas's system is generally adopted, some of the pupils also read Moon's books, and also those in the Roman characters. The schoolmaster, who is blind, reads on six systems, but gives a decided preference to Lucas's. The pupils read quite as rapidly as is necessary, and as correctly as others of the same age with sight. The superintendent of this school says "Lucas's books are

less bulky than those in the Roman type and consequently cheaper." The statement received from Birmingham is similar to the above, "All the pupils read on Lucas's system, it is much liked by them, and preferred to any other; the value of a full orthography is understood, but the bulk and expense are considered objectionable. The Roman type is not generally considered readable." (Whether Alston's or the American Roman type is here referred to is not stated.) The Exeter school furnishes the following information. "Lucas's books are used here, and with but one or two exceptions, all have been able to read the scriptures. Our pupils have tried several systems. All of which they could learn, but they find Lucas's the easier to read." "The London Society for teaching the blind to read," situated in Avenue Road, Regent's Park, has become the head-quarters of Lucas's system. This society has published the whole of the Bible, which is sold in separate books or portions, the Liturgy, and several elementary works. The system has been revised and improved under the superintendence of the Rev. J. W. Gowing. Mr. Moon's printing establishment is at Brighton, but it has agencies at work in London, Birmingham, Edinburgh, and many other places for the introduction of the books. Moon's system has been well-received by the blind and extensively adopted; it is used in the schools of Brighton and Edinburgh. The testimony of Thomas Campbell in the name of the inmates of the asylum in the latter-mentioned city, speaks of Moon's books as superior to all others; his letter traces the efforts made in that asylum with respect to Gall's, Alston's, the American, and Lucas's systems, and his conclusions are entitled to consideration, for they are the results of experience strongly supported by facts which are adduced. He emphatically states "that Mr. Moon's system is not only the best ever devised, but that it is the only one capable of imparting lasting benefits to the working blind." In the various publications advocating the use of this system great stress is laid on its adaptability for the aged, the nervous, and the working blind—those generally in whom the sense of feeling is less than ordinarily acute. It is clear that as a system it can afford to stand on its own merits, and that its adherents need not depreciate other plans while they support its peculiar claims to public favour. This observation is made with reference to the disparaging remarks on other systems in Moon's 'Blind Readers and their Books.' Frere's publications are used in the Liverpool asylum; a society was also established at Blackheath some years ago for teaching the blind to read on Frere's system.

The price of these comparatively expensive books is a consideration which must not be lost sight of in any estimate of their respective claims on public notice. In another part of this article it is stated that a guinea was the sum proposed by Gall for a copy of the gospel of St. John; this, however, was the fancy price of an article new in itself, and for which there was no known market. All this is changed, as will be seen by a comparison of the prices annexed. The Gospel of St. John is now charged 4s. in Lucas's stenographic character; 4s. 6d. in Alston's Roman capitals; 8s. in Moon's arbitrary character. The book of Genesis is 8s. in Lucas's; 10s. in Alston's; 21s. in Moon's. The New Testament is charged 17l. 16s. in Lucas's; 2l. in Alston's; 4l. 17s. in Moon's. The Old Testament, 8l. 1s. 4d. in Lucas's; 7l. 15s. in Alston's; and 11l. 11s. in Moon's, without the books of Leviticus, Numbers, and 2 Chronicles; the addition of these will make the cost not less than 13l. 10s. This discrepancy in price is very great, and it is clear that Mr. Moon must reduce his prices to obtain that favour which he doubtless desires. How strange it is, however, that Alston's Old Testament in Roman capitals, without signs or contractions, can be had for less money than Lucas's with the aid of stenography and its very numerous contractions! Does stenography actually increase the bulk and expense of the books for the blind? The American books are much lower in price than any of the above; the letters are capitals and lower case, but so small that, in this country, they are considered unreadable by the blind. We have four systems in England, the Scriptures in each, besides many other books. And another character is projected. Mr. Littledale, himself blind, and the present superintendent of the school at York, proposes to bring out a "selected alphabet," made up of capitals and lower case letters, readable by any seeing instructor of a blind child; his strong impression being that the Roman character ought not to be set aside for one less universally known, and that no stenographic, or otherwise arbitrary alphabet, will meet the requirements of both children and adults for reading, writing, and accounts.

The writer of this article is not connected with any school for the blind; he does not wish to appear as a partisan of any system of typography for them, he has endeavoured to set forth the excellences and the defects of existing systems of printing, and to show the results as given by their respective advocates, while his wish is to see the superiority of a single system established, in order that the united efforts of all who are now engaged on methods so diverse may be combined for the production of good and cheap books for the blind. Enormous expenses have been incurred, chiefly by the benevolent public, in the purchase of the numerous founts of type, and in the establishment of several printing offices, where one would have sufficed if unanimity had prevailed. Each system has its adherents, but little good has been accomplished compared with such results as would have arisen from unity of purpose and willing co-operation. There cannot be a remunerating sale for the books produced

on all the different systems. Zeal and benevolence may commence a good work of this nature, but it can only become an enduring benefit on the commercial principle. When this principle cannot be applied, zeal and benevolence will fail in providing heart-work and funds which must be so largely wasted. It may be a hard thing for men to sacrifice wishes long indulged and to forget objects for which they have lived and striven, but if the interests of the community, or of a class, require it, men of ardent and kindly feeling will not be backward in making such sacrifices. A conference should be held, partly composed of intelligent blind men, to ascertain whether it is possible to unite all parties in the prosecution of one system of printing, or whether all should persevere in a course which divides the friends of the blind and injures their cause. There are men living who have devoted years to the consideration of the question, and who would be glad to consider it by the lights of science and experience.

BLIND, CENSUS OF THE. In Great Britain and the islands of the British seas (exclusive of Ireland), there were 21,487 totally blind persons at the time of the last census—11,273 males and 10,214 females. Previous to 1851, no account had been taken of the number of the blind in Great Britain and Ireland, so that there are no means of ascertaining whether their number is increasing or decreasing relatively to the population. The numbers above given furnish a proportion of 1 in 975 in Great Britain, 1 in 979 in England and Wales, 1 in 960 in Scotland, and 1 in 837 in the Channel Islands and the Isle of Man. These proportions vary in different parts of the kingdom: in London the proportion is 1 in 1025, and it is nearly the same in the north midland, the south midland, the northern (including Yorkshire), and the south-eastern divisions of the kingdom; the west midland division presents us with 1 in 906; the eastern, 1 in 888; Wales, 1 in 847; and the south-western, 1 in 758: while the north-western district shows only 1 in 1167; the southern counties of Scotland, 1 in 1065; and the northern counties, 1 in 823.

On comparing these results with those obtained in other countries, we find that in the flat champaigns of Belgium, Hanover, portions of Saxony, Prussia, and some other German states, and the plains of Lombardy and Denmark, the proportion is 1 in 950; in the more elevated portions of Saxony, Prussia, Wurtemberg, Nassau, the duchies of Altenburg and Hesse, and also part of Brunswick, 1 in 1340; in Alpine regions, and countries elevated from 2000 to 8000 feet above the sea-level, as in some of the Swiss cantons, Sardinia, &c., 1 in 1500; while in Norway, according to the returns made in 1845, the proportion was 1 in 482. Thus the level portions of Europe present nearly the same results as Britain, while there are certain discrepancies in the above numbers which cannot at present be accounted for.

It has been thought that blindness has been increased by many of the employments followed in populous manufacturing towns; but it is clear, from the census returns, that a much larger proportion of blind persons is found in agricultural than in manufacturing and mining counties. For example, in Wilts, Dorset, Devon, Cornwall, and Somerset (south-western division), the average is 1 in 758; in Essex, Suffolk, and Norfolk, 1 in 888; and in the northern counties of Scotland, which include the Highlands, 1 in 823; while the highest proportion, namely, 1 in 665, is observed in Herefordshire. Contrasting these averages with the following manufacturing or mining counties, no unfavourable inference can be drawn as to the physical effects of manufactures on the sense of sight: in the West Riding of Yorkshire the blind are 1 in 1231; in Cheshire and Lancashire, 1 in 1167; in Durham, 1 in 1163; in Staffordshire, 1 in 1082. It should be remembered, that the asylums and schools which have been established for the reception and instruction of those deprived of sight are located in the principal cities and towns. Where, however, the towns are large, the number of inmates of these establishments only slightly affect the proportion which the blind bear to the general population. In London the proportion is 1 in 1025; in Manchester, 1 in 1107; in Liverpool, 1 in 999; in Birmingham, 1 in 1181. Conclusions unfavourable to the rural districts should not however be deduced from a mere comparison of the proportion of the blind to the population of all ages. Blindness is a common infirmity of old age; and an examination of the ages of the blind shows that nearly one-half of the persons deprived of sight are above 60 years of age. It follows, therefore, that in those localities in which the largest numbers of old men and women are living, the largest proportion of the blind will be found. In the great seats of manufacturing industry the population generally is much younger than in most of the agricultural counties where persons in large numbers, and especially females, are living, in circumstances favourable to longevity, at very advanced ages. Thus, in counties presenting the highest and lowest proportions of blind persons, the influence of age is sufficiently apparent. The proportion of population in Herefordshire aged 60 years and upwards is 10 per cent., while the proportion of blind of the same age is 61 per cent.. In Wilts, Dorset, Devon, Cornwall, and Somerset, the proportion aged 60 years and upwards on the whole population is 9 per cent.; on the blind it is 53 per cent. In Essex, Suffolk, and Norfolk, only 8 per cent. of the whole population attain 60 years and upwards, while of the blind in the same locality, 50 per cent. attain this age. In the northern counties of Scotland, 9 per cent. of the population reach the advanced age specified; while of the blind, 54 per cent. attain the age of 60 and upwards. These four geographical divisions are those in which the highest proportion of blind persons

is found. The four divisions in which the lowest proportions prevail present a very striking contrast with the above. In the West Riding of Yorkshire, the proportion per cent. of the population aged 60 years and upwards is only 6, while the proportion of the blind of the same age is 43 per cent. In Cheshire and Lancashire, the proportion on the whole population is 5, that of the blind 31 per cent. In Durham, the proportion on the population is 6 per cent.; on the blind, 52. In Staffordshire, the proportion of the population is 6 per cent., and of the blind 42.

In the early ages of life the numbers of the blind are not large. Of the 21,487 blind persons in Great Britain, only 2929, or less than 14 per cent., are under 20 years of age,—a circumstance tending to show that cases of blindness at birth are not common. Between 20 and 60 years of age there are 8456 persons, or about 39 per cent. of the whole number; while 10,102 persons, or 47 per cent., are at the advanced ages above 60. These facts point to the conclusion that blindness, in many cases, may have arisen as a natural infirmity attendant upon old age, and also show the great longevity of the blind, notwithstanding the accidents to which they are liable.

It is clearly shown in one of the tables comprised in the Registrar-General's returns, that this affliction is not confined chiefly to particular classes and trades, but exists amongst all ranks and in a great variety of employments. None of the great branches of manufacturing industry seem to be peculiarly liable to it; indeed, the small numbers returned against cotton, linen, silk, woollen cloth, iron, and earthenware, are remarkable when the immense amount of labour employed in these manufactures is considered. Factory workers are however mostly young persons, and none would be employed in the midst of machinery with any defect of vision. Amongst the items which present the largest numbers in the classification of employments, are (in Great Britain): agricultural labourers, 907; labourers not otherwise described, 512; Chelsea pensioners and soldiers, 586; Greenwich pensioners, 70; farmers, 505; domestic servants (chiefly females), 438; weavers, 295; coal-miners, 195; copper- and lead-miners, 68; stone and limestone quarriers, 51. Of the class described as "annuitants," and "living on alms," there are 1062; and 2833 blind paupers are returned in workhouses without any statement as to previous occupation. Of the blind following employments presumed to have been acquired after loss of sight, there are: musicians and teachers of music, 535; mat-sacking- and net-makers, 127, and knitters, 92. With respect to 2853 males and 5960 females, no returns as to their actual or previous pursuits are made.

Of the persons returned as blind in Great Britain, 11,273 are males and 10,214 females. Accidents and diseases resulting in loss of sight are more likely to arise in the employments followed by males than in those of females. The proportions in England and Wales are 113 males to 100 females; in Scotland the difference is slighter,—a result probably traceable to the preponderance of aged women in that country.

The Census Report of the Commissioners on 'The Status of Disease' in Ireland is one of the most valuable documents ever published in this kingdom on the amount and distribution of disease. The inquiry was conducted with much intelligence, and with such precautions as are not usually manifested in matters of this nature. As a first contribution on the permanent maladies to which the inhabitants of a country are liable, its importance can scarcely be over estimated, while it has opened a field for investigation which will hereafter prove a source of lasting benefit to science, and which cannot fail to be a means of directing attention to the afflicted classes whose position it exhibits.

According to the returns made to the Census Commission Office, there were 7587 persons (3588 males and 3999 females) totally deprived of sight resident in Ireland on the 30th March, 1851. Of this number, 1672 were in the civic and 4920 in the rural districts, the former localities including the different asylums and public institutions for the blind; and 995 persons (373 males and 622 females) were in the various workhouses and auxiliary workhouses at the time specified.

Without an accurate medical examination and special inquiry into the circumstances of each case, it would not be possible to define or tabulate the diseases or accidents which produced the large amount of blindness ascertained. How many were born blind there are no means of knowing: congenital cataract, the most frequent cause of blindness from birth, is not very common; loss of sight from purulent ophthalmia and ulceration of cornea is the most common; and in some districts, particularly in the west of Ireland, internal inflammations of the eyes of a rheumatic character prevail to a great extent, and are a frequent cause of blindness.

The limited space we can devote to this subject prevents us from giving the important Tables included in the Report, from which we have drawn the above facts and observations. To that Report all who are interested in the state of the blind in Ireland may be referred. We give the heads of these Tables.

Table I. shows the number of blind in the civic and rural districts and the workhouses, together with the proportion of males to females, and proportion to the population in the several provinces, counties, cities, and towns in Ireland.

Table II. shows by ages and sexes the number and previous or present occupations of the blind.

Table III. shows by ages and sexes the state of education and

marriage among the blind in workhouses and in the civic and rural districts.

Table IV. shows the number, distribution, means of support, date of erection, and other circumstances relating to the various asylums for the blind in Ireland.

Table V. (taken from the reports of St. Mark's Ophthalmic Hospital, Dublin, from 1844 to 1852) shows the varieties of diseases and accidents of the eye in 11,233 instances, together with the colour of the eye in 7354 cases.

(Compiled and extracted from the *Official Returns of the Census of Great Britain in 1851*, published under the authority of the Registrar-General; and from *The Census of Ireland for 1851,—Report on the Status of Disease.*)

BLIND, EDUCATION OF THE. Blindness perhaps meets with more general sympathy than any other calamity. Our most beautiful and correct perceptions are derived through the medium of sight; the want therefore of such a medium is an evil for which no other possession can compensate. Hence it is that we at first consider the blind as an unfortunate race, whose conceptions must not only be confined to that narrow sphere in which they live and move, but, as far as a knowledge of external objects is concerned, must be limited to that imperfect acquaintance which is obtained by the sense of feeling. Looking however further into the subject, we find that the sense of hearing is constantly communicating knowledge to a blind person which helps him to analyse and compare; from which he draws inferences, and arrives at conclusions more or less correct; that constant experience enables him to modify any false impressions which he may have received; that association, memory, and other powers of the mind are active; that the senses of smell and taste are continually contributing some small additions to his stores of knowledge; and that, by these united means, he may become well-informed on subjects of ordinary discourse, though labouring under a disadvantage at first appearance insurmountable. The self-education of a child born blind commences as soon as that of one who sees; and if parents in such cases would give themselves trouble in its instruction, instead of looking upon their case as one of despair, they would be amply rewarded by the improvement, surpassing all expectation, which their child would make. They would find little difficulty in communicating to him the names, shapes, and many other particulars of objects; and indeed language, with the exception of some classes of words denoting colour, or other qualities which can only be known by means of sight, might be as perfectly conveyed to him as to the child possessing all its senses. They would find that they could give correct ideas of numbers to a large amount by means of tangible objects, and of still larger numbers by analogy; that they could also give ideas of time, space, distance; so as to impress him with correct notions of the earth, its size, inhabitants, productions, climates; the occupations, the pleasures, and the pains of mankind. All this is knowledge of a useful and pleasing kind, and many parents would become highly interested in such a work; they would soon find that they might proceed still farther, and enable their blind child either to attain a certain degree of perfection in some mechanical art, or, by educating his higher faculties, train him to occupy a more intellectual and important station.

The parent who reasons and acts thus upon his child's calamity, will be supported and animated by the knowledge that he is supplying by his own attention the defect of nature, and that he is educating his child to fulfil important duties with the same pleasure to himself that others have who possess a more perfect organisation, and that he is providing a most efficient check to listlessness and mental torpor.

The ear has been happily called "the vestibule of the soul," and the annals of the blind who have become illustrious confirm the remark, for they show that few intellectual studies are inaccessible to them. It has even been said, and has received a kind of universal assent among those who have associated much with them, that in certain branches of study they have a facility which others rarely possess. The blind appear to have immense advantages over the deaf; their intercourse with the outward world, by means of speech, is more direct, and consequently more rapid, and their knowledge of passing events is equal to that of mankind generally. The deaf and dumb see indeed all that passes within their immediate sphere; but owing to the circuitous mode of communication which they have to adopt, they can know little beyond it, and enter very partially into the spirit of passing events. In addition to this, finding that they do not always understand perfectly, nor guess rightly, their temper becomes impatient, and their countenance acquires an anxious or irritable expression, which is sometimes mistaken for cleverness. We know of no deaf persons who have attained to any great degree of eminence, even under circumstances favourable to the development of their powers; but with regard to the blind, they have enriched the arts, the sciences, and literature by their successful pursuits, and not unfrequently under circumstances of extraordinary difficulty. Viewing both these classes of men as devoid of education, dependent upon themselves for support, and for the enjoyment of life, the blind are *physically* greater objects of compassion than the deaf, because, without peculiar modes of education suited to their privation, they cannot obtain a livelihood; but so far as happiness is dependent upon knowledge, and from this source some of the purest enjoyments arise, they are nearly on a level with ordinary men. Through the ear they can acquire knowledge of the highest order, and cannot

remain long in any company of their fellow-men without becoming in some degree wiser. The case of the deaf is the reverse of this; they are not *physically* so dependent as the blind: having the advantage of sight, they may apply themselves to and acquire the simpler imitative arts, and thus earn a subsistence, but *mentally* they are little above brutes; they can know nothing of the things around them, they feel themselves depressed and degraded among men; the language, the customs, the enjoyments of society, where these rise higher than what seems to exist among the more perfect animals, are to them unknown, and by them unregarded; and it requires only a small amount of reflection to perceive that an uneducated deaf person is not morally responsible for his conduct.

These remarks, and the comparison with which we have opened this subject, are not designed to show that the blind are less in need of education than the deaf and dumb; we are advocates for education in its fullest extent among all classes, but more particularly among persons who labour under impediments so distressing as those we have mentioned. Our advice would be to educate such persons as highly as possible, to improve especially those faculties which they appear to possess in a superior degree to mankind generally; but not to waste time and labour in endeavouring to instruct them in arts in which they can never attain to an equality with persons who possess the full enjoyment of their senses.

In this and in other countries, some attention has been paid to alleviate the sufferings and diminish the ignorance of the blind; the hand of kindness has been extended to lead them into society, and the voice of sympathy has been heard by them in the midst of their darkness. Asylums in several parts of Great Britain have rescued a few from a life of listlessness and anxious care, who have been instructed in various arts with the view of wholly or partially relieving them from dependence on their friends, their parishes, or the temporary bounty of the benevolent. To all who are entrusted with the charge of the pauper blind, and especially to boards of guardians, the words of Dr. Lettsom, the benevolent advocate of the charities for the indigent blind, may be addressed: "He who enables a blind person, without any excess of labour, to earn his own livelihood, does him more real service than if he had pensioned him for life."

It is invariably found that persons who are deficient in one sense exercise those that are left to them more constantly, and for this reason more accurately; for the senses are improved or educated by exercise. The exquisite fineness of touch and smell in the blind, the quickness in the eye of the deaf, the accuracy with which a seaman discovers a distant vessel long before it is discernible to the unaccustomed eye of a landsman, and the acuteness of sight, hearing, and smelling, in many savage tribes, are all to be referred to the same cause, namely, the constant exercise of those organs. Those persons who are deprived of one or other of their senses will, to a great degree, supply the deficiency by the aid of those which they still retain. Hearing and touch are especially cultivated by the blind; by the first they recognise speech, and the endless variations and modifications of sound; by the second they become acquainted with the external form

of objects. The chief art of the instructor of the blind therefore consists in supplying through an indirect medium those ideas of which his pupil cannot obtain a conception through the ordinary channels; and in doing this he will act wisely to ascertain what ideas on kindred subjects his pupil possesses, whether such are true or false, and by what process he became possessed of them; to become, in fact, the pupil of his pupil; to draw forth the stock of knowledge already attained, in order to form a ground-work on which to proceed with his future instructions.

The mode which would probably first occur to a teacher in the intellectual education of the blind would be lessons delivered orally, illustrated by such analogies as would enable them to follow their teacher, taken, if necessary, from objects appealing to their senses. At first they would advance by slow degrees in comparison with pupils who see, but this very slowness would be accompanied by a sureness which would amply repay the pains taken to make the lessons understood. It is a fault in ordinary schools that the first steps are taken too rapidly, and one advance too quickly follows upon a former. Such schools might derive a useful lesson from the methods used in the instruction of those who are deprived of one or other of their senses. From oral instruction, the transition to a palpable language is natural. Accordingly, we find that the invention of *characters in relief* was among the earliest measures taken for instructing the blind. [BLIND, ALPHABETS FOR THE.]

An ingenious *string alphabet* was contrived a few years ago, by David Macbeath, a blind teacher in the Edinburgh School, in conjunction with Robert Milne, one of his blind companions. The following is their description of this invention: "The string alphabet is formed by so knotting a cord, that the protuberances made upon it may be qualified, by their shape, size, and situation, for signifying the elements of language. The letters of this alphabet are distributed into seven classes, which are distinguished by certain knots or other marks; each class comprehends four letters, except the last, which comprehends but two. The first, or A class, is distinguished by a large round knot; the second, or E class, by a knot projecting from the line; the third, or I class, by the series of links vulgarly called 'the drummer's plait'; the fourth, or M class, by a simple noose; the fifth, or Q class, by a noose with a line drawn through it; the sixth or U class, by a noose with a net-knot cast on it; and the seventh or Y class, by a twisted noose. The first letter of each class is denoted by the simple characteristic of its respective class; the second, by the characteristic and a common knot close to it; the third, by the characteristic and a common knot half an inch from it; and the fourth, by the characteristic and a common knot an inch from it. Thus, A is simply a large round knot; B is a large round knot with a common knot close to it; C is a large round knot with a common knot half an inch from it; and D is a large round knot with a common knot an inch from it, and so on." The alphabet above described is found by experience to answer completely the purpose for which it was invented. In the Glasgow Asylum, the greater part of the Gospel according to St. Mark, the 119th Psalm, and other passages of Scripture and history have been

The String Alphabet.

executed in this alphabet. The knotted string is wound round a vertical frame, which revolves, and passes from the reader as he proceeds.

This alphabet reminds us of the *Quipos*, or knot-records of Peru, in which the history of their country was recorded long before the discovery of America by the Spaniards. Their *quipos* were formed of the

intestines of animals, and there is a similar diversity in their symbols with that in the string-alphabet of which we are speaking. An account of these quipos was published in London in 1827. They were purchased by Alexander Strong for ten pounds, from a person who bought them at Buenos Ayres.

In further explanation of the string-alphabet the inventors say, "It

must readily occur to every one that the employment of an alphabet composed in the manner which has been explained, will ever be necessarily tedious; but it should be borne in mind that there is no supposable system of tangible figures significant of thought, that is not more or less liable to the same objection. The inventors are aware that among the different methods by which people at a distance might be enabled to hold mutual intercourse through the medium of a language addressed to the touch, there are some that would doubtless be more expeditious than theirs; but they flatter themselves that, when all the advantages and disadvantages of each particular method are duly considered, the plan which they have been led to adopt will appear, upon the whole, decidedly the best. There can scarcely be any system of tangible signs, which it would be less difficult either to learn or to remember; since a person of ordinary intellect may easily acquire a thorough knowledge of the string-alphabet in an hour and retain it for ever. Yet the inventors can assure their readers that it is impossible for the pen or the press to convey ideas with greater precision. Besides the highly important properties of simplicity and accuracy which their scheme unites, and in which it has not been surpassed, it possesses various minor, nor yet inconsiderable advantages, in which it is presumed it cannot be equalled by anything of its kind. For example, its tactile representations of articulate sounds are easily portable—the materials of which they are constructed may always be procured at a trifling expense—and the apparatus necessary for their construction is extremely simple. In addition to the letters of the alphabet, there have been contrived arithmetical figures, which it is hoped will be of great utility, as the remembrance of numbers is often found peculiarly difficult. Palpable commas, semicolons, &c. have likewise been provided to be used, when judged requisite. The inventors have only to add, that sensible of the happy results of the invention to themselves, and commiserating the fate of their fellow-prisoners of darkness, they most earnestly recommend to all intrusted with the education of persons deprived of sight carefully to instruct them in the principles of orthography, as the blind being in general unable to spell is the chief obstacle to their deriving, from the new mode of signifying thought, the much-wanted benefit which it is designed to extend to their melancholy circumstances."

We entirely agree in the views here taken of the string-alphabet; as an auxiliary to the blind in the acquirement and application of language, and in the absence of a tangible writing on paper, we think no invention is superior to it, and we should be glad to have seen it in more common use among the blind in our recent inquiries at various institutions. The advice to instruct the blind carefully in spelling is important; for if this acquirement be not made, they cannot communicate by language with their fellow men otherwise than orally. To those blind persons who have lived together in institutions, and formed friendships which they wish to continue when separated by distance, the string-alphabet offers a mode of correspondence as perfect as our pen, one too which may be intrusted to ordinary persons to convey without any probability of the communication being deciphered.

David Macbeath, one of the inventors, was connected with the Edinburgh Asylum, as pupil and teacher, for twenty-five years. His inventions for teaching were numerous, and applicable to instruction in music, arithmetic, and mathematics. His string-alphabet was fully described in the 'Edinburgh Philosophical Journal,' some years ago. He conducted the public examinations of the Edinburgh pupils, where he never failed to excite the interest and attention of those present towards the objects of their solicitude.

In the infancy of the art of teaching the blind, *raised music* was invented, in order that they might be enabled to acquire their lessons independent of a master. This invention is at present little used, for the constant practice of those who pursue this branch of study is a continual exercise of the memory, and they are able to learn very long pieces by the ear alone. The reason assigned by Dr. Guillié for the disuse of embossed music is very satisfactory, "the scholar could not read with his fingers and perform at the same time." Thorough bass is however as readily studied by the blind as by the seeing, by means of "Tansure's Musical Board," described in his 'Musical Grammar.' This board is three feet long, about eight or nine inches wide, and has two staves, with ledger lines, above, between, and below. These are raised upon the surface of the board about one-sixteenth of an inch; the top of the stave lines being flat, while that of the ledger lines is round. It is pierced all over with little holes, so as to receive the pins, which represent the notes. We may here mention the invention of Don Jaime Isern, the object of which is to enable a blind composer to transfer his thoughts to paper in the usual musical notation, without the necessity of employing an amanuensis. For this invention the large silver medal of the London Society for the Encouragement of Arts, Manufactures, and Commerce was given to Don J. Isern in 1827. There is a full description of it, with illustrative engravings, in vol. xlv. of the 'Society's Transactions.' In the same volume there is an interesting communication on the subject of types for the blind, by Mr. G. Gibson of Birmingham. This communication is connected with various inventions which we have had the pleasure of inspecting, and of which we shall give a short account, referring our readers who desire to be made perfectly acquainted with the invention to the work above mentioned. Mr.

Gibson's aim has been to supply the blind with a mode of writing and keeping their own accounts. "A cube of wood, or of any other convenient material, the size of which will depend on the delicacy of touch in each blind person, is to have raised on one side of it a letter, or figure, or stop, in the manner of a printer's type. On the opposite or lower side of the cube is a representation of the same character as is on the upper side, but formed of needle-points inserted into the wood. If therefore a piece of paper be laid on a cushion, or surface of felt, and the type be pressed down, the points will enter the paper, and form on the under surface of it a raised or embossed representation, by the projection of the burs where the points have penetrated, and this embossed character may be distinguished, and consequently read by the touch." In its outward appearance, the whole apparatus of Mr. Gibson forms a small piece of cabinet furniture. When the top is thrown open an even surface of cushion presents itself. Upon this there is a flat piece of mahogany about an inch broad, which can be moved from one notch to another, to any part of the desk. This is for the letters to lie against, like the composing-stick of a printer. The letters he uses are a composition of tin and lead; the upper surface is elevated so that he can distinguish the letter, and the under surface has inserted in it needle-points of the shape of the letter on the upper surface. In writing the Lord's Prayer, after the paper is placed, he takes O out of its division, and puts it at the beginning of the line, then U, then R, gently pressing each letter down, as he puts it next the preceding one. At the end of a word he inserts a small mahogany space, and proceeds till his performance is complete; whether it be a copy of anything which he wishes to make, or an original piece of composition. It will be observed that, by putting two or more pieces of paper underneath his pointed types, copies will be multiplied. The letters are in small divisions, which occupy side-drawers in his printing cabinet. The use of this machine implies more knowledge than the uneducated blind possess, as they must know how to spell. However, it is a part of its object to teach spelling. For this communication to the London Society for the Encouragement of Arts, &c., Mr. Gibson was presented with the gold Vulcan medal of the Society. Another of Mr. Gibson's inventions may be here noticed. It forms a drawer of the cabinet above-mentioned, and is intended for working the rules of arithmetic. This Mr. G. calls his slate. It is divided into rows by elevated slips of wood, along which the figures are to slide. Like the types they are formed of metal, but have no needle-points underneath. We have seen him perform examples in multiplication and other rules by this apparatus, which is simply and beautifully conceived. It is obvious that all the elementary operations in arithmetic may be performed by it, and that by the union of this and the writing apparatus, a blind person may write his own letters, and keep his own accounts. We have dwelt upon the subject of reading and writing for the blind, feeling that they are deserving of all the importance which can be attached to them. Lieutenant Holman, the blind traveller, used Wedgwood's apparatus for writing in the dark. A very ingenious instrument of this nature has been invented by the late Mr. Hughes, who was for many years the governor of the School for the Blind at Manchester. We return to the early methods pursued in this art.

Embossed maps and globes for teaching geography would naturally be suggested to those persons who were engaged in teaching reading to the blind by raised figures. M. Weissebourg, a blind man of Mannheim, appears to have been the first person who made relief-maps; up to which time the instruction given to the blind on geography was merely oral. Various methods for producing maps of this character are now employed.

Palpable methods have also been adopted for making the blind acquainted with different branches of astronomical knowledge, and, in addition to raised maps of the heavens, various ingenious instruments have been contrived to further their progress in the science of astronomy. The application of such apparatus to the purposes of teaching has been attended with encouraging success. We shall detail some of the methods pursued in teaching arithmetic when we speak of the Edinburgh Institution, where the well-known invention of Dr. Saunderson has been so much improved that, by its means, any operation may be readily performed. For a description of the original invention, which was the united work of Dr. Moyes and Dr. Saunderson, we refer to the article 'Blind' in Rees's 'Cyclopædia,' or in the 'Encyclopædia Britannica.' By the improvements which we shall describe, it will be seen how greatly the simplicity of the contrivance has been increased. Previous to these tangible methods of teaching arithmetic the blind were instructed on this subject orally, the process on their part being entirely mental. A publication of late years, which is intended exclusively for the blind, is of a higher character and aim than any that have preceded it, though not one which will generally be considered as equal to many of those mentioned, in point of utility. The work to which we allude is an elementary treatise on mathematics by the Rev. William Taylor of York, called 'The Diagrams of Euclid's Elements of Geometry, arranged according to Simpson's edition in an embossed or tangible form, for the use of blind persons who wish to enter upon the study of that noble science,' York, 1828. As a means of leading to the acquisition of a science for which some blind persons have shown a predilection, this beautifully executed work is of great value, and we hope that the blind generally who show a superior

aptitude for the exact sciences, even though instructed in a degree at the public expense, will have all the advantages which works like Mr Taylor's aided by good instructors can confer. It is stated that some of the pupils of the London School for the Indigent Blind worked a few problems for Mr. Taylor, their examiner, at their examination last Christmas.

Institutions of a philanthropic tendency have frequently originated with members, individual or collective, of learned societies; and such societies have lent their assistance and patronage to various efforts for advancing the condition of mankind, and removing the obstacles to improvement. The attempts of M. Haüy to systematise a plan for the education of the blind are the first which are deserving of especial notice. His methods were submitted to the Academy of Sciences of Paris, where they received all the encouragement he looked for. The commissioners chosen to report upon the means which he proposed to employ suggested to the Academy not only to bestow its approbation upon M. Haüy, but also to invite him to publish his methods, and to assure him of their readiness to receive from him an account of his future progress. It appears that many of the plans recommended by Haüy in his 'Essay on the Education of the Blind,' were not so much his own inventions as adaptations of the ingenious contrivances of individuals of different ages, and in different countries, who had preceded him in this benevolent work. The celebrity of certain blind individuals, partly the result perhaps of pains-taking teachers, and partly of their own highly gifted minds, had reached the ears of Haüy. By a happy exercise of benevolence and talent, aided by that enthusiasm without which the greatest labour is ineffectual, he formed the outline of a system of instruction, which required only time, and the modifications which discover themselves in every course of rational teaching, to be brought into successful operation. He wished to make the sense of touch do that for the blind which the Abbé de l'Epée had made the sense of sight do for the deaf and dumb. He wished to see the fingers of the blind employed in reading written language, and for this purpose he invented the noble art of printing in relief, which will hand down the name of Valentine Haüy with honour to posterity. Haüy offered to instruct gratuitously the blind children who were under the care of the Philanthropic Society. He commenced his instructions in 1784, and taught his pupils reading, writing, arithmetic, geography, composing types, and printing. In 1786 public exercises were performed by the pupils at Versailles, in the presence of the king; these exercises excited much astonishment, and there seemed to be little doubt of the stability and success of the undertaking. Large funds were subscribed, and the school was filled with pupils; but the commencement had been made on a scale too extensive for its regular maintenance, the warmth of popular feeling cooled, and as the institution was unsupported by government, Haüy never enjoyed the fruits for which he toiled. His school was not however suffered to fall entirely; it was taken up by the Constituent Assembly of the Revolution, and has since been supported at the expense of the government. The establishment of which we are speaking is the School for the Young Blind at Paris.

There are at Paris two celebrated institutions for the blind. The more ancient of these is the Hôpital Royale des Quinze Vingts, founded by St. Louis in 1260, for the reception of such of his soldiers as had lost their sight in the East. At its first establishment it consisted of blind and seeing persons, the latter being the conductors of the former. As its name indicates, it receives *fifteen score*, or three hundred blind persons. This noble asylum continues, as it was originally placed, under the government of the grand almoner of France. To obtain admission it is necessary that applicants be blind and indigent; they are admitted from all parts of the kingdom, are lodged in the hospital, and receive twenty-four sous (about a shilling) a day for their food and clothing. No instruction is afforded to the inmates of the Quinze Vingts; some of them, however, execute works, which, for their ingenuity, attract and deserve attention. The other Parisian establishment for the blind is the Institution Royale des Jeunes Aveugles, of which Haüy was the founder. It contains about a hundred young persons of both sexes, who are maintained and educated at the expense of the state for eight years. Paying pupils are also admitted. During the last quarter of a century the education of the blind has made great advances, as will be seen when the present state of the various establishments is compared with their actual condition, as described in the article BLIND of the 'Penny Cyclopædia.' The writer of that essay lamented that there was so much that appeared to him censurable, and that called for animadversion in the modes of education pursued in some of the schools for the blind. The article was, however, transmitted to three of these schools previous to its publication, and it was allowed to be a correct statement of facts. A great change for the better has since taken place, not only in the schools referred to, but in others also; new asylums have been established, and the attention of many experienced men has been directed to various branches of education, and especially to the provision of books in raised type, of which an account is given in the article BLIND, ALPHABETS FOR THE.

The first British Asylum for the Blind was established at Liverpool, in the year 1791. This institution has hitherto been liberally supported. During the year 1858, its expenditure was 3000*l.*, its income about 3400*l.*, derived from goods disposed of (the work of its inmates), from the payments made on behalf of the pupils, from legacies, dona-

tions, and subscriptions, from dividends, and the pew-rents of its chapel. The sums received for articles manufactured exceeded 900*l.*, but the produce of these labours does not assist the funds of the establishment. The instruction of the blind in manual labour seems to be the primary object with the directors of the institution. The trades which are taught are those of basket-making, rope-making, weaving, shoemaking, sewing, knitting and plaiting sash-line. The most profitable of these arts is the rope-making; the locality of the institution contributes to the advantages derived from this trade. The sugar-houses require so vast a supply of cordage, that it can scarcely be furnished in a sufficient quantity. The next most profitable labour is the weaving of carpets, lobby-cloths, and bear-rugs. Masters possessing sight are regularly employed in teaching the various trades; the reasons why the institution derives no pecuniary advantage from the extensive labours carried on are sufficiently obvious when the expense of experienced masters is considered, the waste of materials by the labourers who are chiefly learners, and their quitting the asylum when they can earn enough to maintain themselves.

The total number of persons who have been received into this asylum from its commencement to the publication of the report, January 1859, was 1429. Some very interesting details are given in the same document on the causes of the calamity under which the pupils labour, so far as could be ascertained by the officers of the institution.

LIVERPOOL INSTITUTION, TOTAL NUMBER RECEIVED 1429.

	Totally.	Partially.	Total.
Blind from their birth	70	49	119
" " small-pox	202	48	250

" " after convulsions	3	3	6
" " from causes not mentioned, or imperfectly described	28	27	55
	878	551	1429

From the reports of the Liverpool Asylum, as well as from others which we have seen, the blind seem to be pretty equally scattered in all parts of the kingdom. Of the 1429 persons who have been inmates of the Liverpool Asylum, 225 have belonged to Liverpool, 294 to other parishes in Lancashire, and 910 to distant parts of the kingdom. A large proportion of the income of the institution is derived from Liverpool and its vicinity. The blind of that district have therefore a just priority of admission. There are 79 pupils in the Liverpool Asylum; 18 were admitted in 1858, and 21 left. Among those thus admitted, 8 are between fourteen and twenty, 4 are between twenty and thirty years old, 4 are upwards of thirty, and of 2 the ages are not specified. Most of those who have completed their education receive a gratuity of from two to five guineas when they quit the asylum, which sum is intended to assist them in procuring a few tools and materials for commencing the trades they may have been taught. This provision is both benevolent and wise; for there are numerous cases which come under the notice of the directors where poverty accompanies the deprivation of sight, and where, consequently, the instruction imparted would be of no practical benefit were not some means afforded of making it available to provide for their common necessities. The observances of religion appear to be regularly regarded: prayers are read in the chapel morning and evening, and the chaplain attends twice in each week to teach the catechism. The appointed hours for labour in the Liverpool Asylum are from six in the morning to six in the evening, one hour being allowed for breakfast and recreation, and another for dinner. Some of the pupils occupy a large portion of their time in the practice of music, singing, reading, &c. Frere's system of raised type is used, but the superintendent is not prepared to say which of the several series of books is most eligible for the blind. There are no fixed hours for acquiring the art of reading by touch, but instruction is given at such times as the teachers can spare from their other duties. Many of the inmates are middle-aged adults, whose object in entering the institution is expressly to acquire facility in some employment by which they can maintain themselves, and who leave as soon as they have succeeded in learning a trade, some of them only remaining under instruction from six to twelve months. This information has been supplied by the superintendent.

In the year 1792 an Asylum for the Blind was established in Edinburgh. The benevolent Dr. Blacklock, who resided in that city many years, had long anxiously wished that such an establishment should be formed for the education of those persons who, like himself, were deprived of sight. He mentioned his wishes to his friend Mr. David Miller, who was also blind, and was himself an eminent example of what might be effected under the influence of early and judicious instruction. In the year mentioned, it was determined by Mr. Miller and the Rev. Dr. David Johnston, of Leith, that an attempt should be

made to provide an asylum, and means were taken to call public attention to the object. Mr. Miller communicated with the Abbé Haüy, and in many ways rendered important services during the infancy of the institution. The chief end in the formation of the contemplated asylum, next to imparting ordinary instruction (orally, it is presumed), and imbuing the minds of the objects with religious truth, was to place them under such superintendence as should train them in those trades in which the blind "are best fitted to excel;" at the same time rewarding them for their labours according to their progress and proficiency. In later years the directors of the asylum have extended their views, devoting increased attention to the intellectual culture of the pupils; but still the main object appears to be that of training them to habits of manual labour. The economical character of the Edinburgh Asylum must be a striking feature to all who compare its expenditure, considering the amount of good it accomplishes, with that of similar institutions. We have frequently heard of the excellent management of the public charities of Edinburgh; but in none is such management more visible than in this. In 1806 the directors formed a separate establishment for females, and since that time they have opened a school for the instruction of the young blind. It is by early training only that the blind, in common with others, can be brought under an effectual mental and moral discipline. By giving instruction to the young in the higher departments of knowledge, and by thus raising the intellectual character to the elevation of which it is capable, we are of opinion the directors will discover that the arts in which the blind are best fitted to excel are not the ordinary mechanical trades, to which, in our British institutions, and too generally abroad, all higher considerations have been sacrificed. Why are not their mental powers, which are unaffected by their physical calamity, cultivated? Such cultivation will qualify them for occupations in which they may succeed as well as those who possess the advantages of sight. The enlightened policy of the directors of the Edinburgh Institution has placed them in the first rank among the benefactors of the blind: their school for the young is a most interesting section of their establishment; and it may be hoped that many of its pupils will be trained to higher occupations than those of basket-making, weaving, &c. We do not anticipate that all the blind can be exempted from manual labour, any more than that all other men are fitted for employments requiring a high degree of intellectual vigour, and acquirements which even the greater portion of mankind are unable or unwilling to make: but we do not hesitate to affirm that the blind have been systematically trained in arts in which they never can enter into competition with seeing persons; and that they have not been sufficiently educated in that kind of knowledge in which they might have become at least as perfect as those who possess all their faculties. The former part of our proposition is allowed by the directors of the Edinburgh Asylum, who say that "when they (the blind) become as skilful workmen as their circumstances admit, they still labour under a disadvantage unknown

to others." An argument which might with great propriety be used to enforce the advantage of mental cultivation in preference to manual dexterity, is the loss invariably attendant on the manufactures carried on at the asylums. It appears to us from our examination into the expenses of different establishments, that the more extensive the scale on which the manual arts are conducted, the greater the losses, from waste of materials, a succession of learners, &c. On the score of cheapness therefore it is desirable that such operations should be confined within as narrow limits as may seem prudent, and that intellectual education should be extended as widely as the talents and qualifications of the pupils will allow. Instead of the accounts of such institutions showing so great an amount of positive losses, we should not only see this item reduced, but find the pupils qualified for a sphere of usefulness superior to any which they can ever reach by any attainable degree of dexterity in manual occupations.

In the Edinburgh Asylum, the whole machinery seemed to be of a high order; the devoted attention of the different officers is visible in the discipline and happiness of the inmates, and there can be no doubt that the institution is effecting great good. The young blind are instructed in reciting the scriptures, in spelling, in grammar, in vocal and instrumental music, in reading, by means of the sense of feeling; in writing, arithmetic, mathematics, history, geography, and astronomy. The means by which instruction in these various branches is conveyed have been mentioned; in all institutions of this nature they must be generally the same, varying perhaps in some of their details. Several of the mechanical contrivances for conveying scientific knowledge to the pupils are the inventions of Mr. Johnston, the former secretary (nephew of Dr. Johnston, who was named as one of the founders of the institution), in conjunction with Professor Wallace, a gentleman who was deeply interested in all that concerned the institution. An orrery, a cometarium, and raised maps of the heavens, all so constructed as to convey information by the touch,—while the reasoning powers are at the same time addressed,—are among the inventions of these gentlemen. The map of the world is described as comprising "the eastern and western hemispheres, represented on each side of a circular board. The land is made rough, the seas, lakes, and rivers smooth. Towns are represented by small pins. Mountains are ridged, and boundaries simply raised. Degrees of latitude are marked round the edge of the circle, of longitude along the equator, which is raised above the surface of the earth. The orrery represents the orbits of the planets by brass circles, and the planets themselves are shown by spheres indicative of their relative dimensions; the spheres slide upon the brass orbits. The ecliptic exhibits raised figures of the signs of the zodiac, the degrees of the circle, and the days of the month, all tangible, and adapted to the learner who has to depend upon touch for his impressions. The arithmetic board is 16 inches by 12, and contains 400 pentagonal holes with a space of a quarter of an inch between each. The pin is simply a pentagon, with a projection at one end on an angle,

The Arithmetic Board.

and on the other end on the side. Being placed in the board, with a corner projection to the left upper corner of the board, it represents 1; proceeding to the right upper corner it is 3; the next corner in succession is 5; the next 7, and the last 9. In like manner the side projection, by being turned to the sides of the hole, progressively gives 2, 4, 6, 8, 0. The size of the pentagon, and a drawing of the pin, showing the projections on the side and angle, are given with the board above.

By the use of this board the pupils may be carried to any extent in arithmetical knowledge, and make their calculations with as much satisfaction as those who see. The last improvements in the Arithmetic Board were made by William Lang, at first an inmate of the Edinburgh Asylum, afterwards of that of Glasgow. Further to illustrate its use an example is given below of a sum in multiplication, which will be at once understood on comparing it with the board above; this example shows $259 \times 4 = 1036$. The pentagons represent the pins with their projections as supposed to be in the holes of the Arithmetic Board.

We have the testimony of Dr. Guillié, that the blind study the exact sciences under great advantages, and with remarkable success; but we cannot agree with the doctor that the blind, any more than *les clair-voyans* have a natural disposition for mathematical studies.

The eminent success of Saunderson, Moyes, Gough, and others, afford sufficient proof that blindness is no great impediment to such pursuits;

there may possibly be some advantages consequent on the degree of abstraction which appears necessarily to accompany blindness. On this supposition however we do not lay much stress, because we cannot admit that there is *naturally* any compensative principle by which men who labour under one defect or deprivation, are enabled to exercise the powers which are left to them with greater accuracy than others

who have no such deficiency. If a seeing person would cultivate his sense of feeling to the same extent as the blind, his perceptions of touch would be as delicate as those of the blind man. It is not probable that so refined a cultivation will ever be tested by experience, as it would require a greater degree of philosophical curiosity than we ever witnessed or heard of, and be attended with a longer and more painful effort than we think any one would voluntarily undergo for the sake of making the experiment.

The Bristol Asylum for the Blind owed its origin to the benevolent exertions of two members of the Society of Friends, Messrs. Bath and Fox. It was opened in 1793, in a disused Baptist meeting-house. After attempting several of the trades, basket-making was commenced, and although other occupations are followed, fine and coarse baskets have been the staple manufacture of this asylum to the present time. In 1803 its funds were so greatly increased that the committee of management were enabled to spend 1800*l.* on the purchase of premises in Lower Magdalen Lane, and its operations were there carried on till its removal in 1838 to the present eligible situation at the top of Park Street, where a building was erected in the early English style, with a chapel in architecture of a later character, and became a prominent ornament to the city. This building provides workshops for 100 pupils, and bedrooms for 70. At a subsequent date, rooms were added for washing, baths, and shower-baths, and a more recent purchase of land in Tyndall's Park gives ample room for exercise and amusement. If the utility of the asylum may be deduced from the progressive increment of the sales the conclusion will be satisfactory, as in 1794, its second year, their amount was 18*l.* 8*s.* 6*d.*, and in the year ending 1857 there was received "for baskets, table-mats, flower-stands, hearth-rugs, door-mats, and knitting, 1088*l.* 2*s.* 2*d.*"

The distribution of time in mental occupation and manual labour is as follows:—The pupils rise at 6 a.m., and work or take exercise till breakfast at 8 o'clock; at half-past 8 prayers are read by the master; the school-room is then occupied from 9 to 6, the classes being changed every hour. By this arrangement each pupil receives two hours' instruction daily. One hour in the day is allotted to musical practice, two hours' instruction being given to each pupil every week; the remaining time till 6 o'clock is occupied in manual labour, and, as occasion offers, the master or matron reads to the pupils while at work; but three days in the week they read collectively. On two evenings the pupils assemble for practice with the music-master, and the remaining evening they attend the chaplain for religious instruction. Supper is served at half-past 7; immediately after prayers are read by the matron, and the household retires to rest about 10.

Instruction in the Bristol Asylum is conducted by a chaplain; by the master, who teaches reading, arithmetic, geography, and history, and who has a blind assistant of either sex; by a music-master, with similar aid; by a basket-maker for the men, who has also two blind assistants; and by a female basket-maker, with one assistant possessed of sight and one who is blind. Great advantage is thought to be obtained by this employment of blind teachers, especially in the initiation of new pupils. The system of printing preferred in this asylum is that in the Roman character, by the late Mr. Alston of Glasgow. The books published by that gentleman were introduced in 1837, and have continued in daily use to the present time. A 'Life of James Watt,' an 'Elementary Geography,' 'Our Lord's Sermon on the Mount,' and a 'First Reading Book,' have been published at this institution in Roman capitals and lower case.

The report of the chaplain on the scriptural instruction of the pupils is very satisfactory. The report from which we quote states that nine of the younger ones had received confirmation, five of whom had become communicants. The master's report to the committee on their secular instruction is equally satisfactory: biography, history, arithmetic, grammar, and geography are the subjects of his statement; while the music-master considers the progress of some and the proficiency of others in music and singing as deserving commendation. All who are engaged in the management speak of the pupils as intelligent and well-disposed, and as manifesting a spirit of cheerful obedience. The welfare and conduct of the former pupils is not overlooked in the report of the committee: special instances are recorded of some of the advantages the asylum has conferred on individuals, and it is also stated that satisfactory accounts continue to be received from others, who, from the trades they learned and the industrial habits they acquired while at the asylum, are now earning a living in such a manner as not only to reflect credit upon themselves, but also on the institution. There are in the Bristol Asylum 66 pupils: males, 42; females, 24; upwards of 40 of them are under 20 years of age.

The School for the Indigent Blind in London was established in 1799 by four gentlemen of the metropolis,—Messrs. Ware, Bosanquet, Boddington, and Houlston. At first the pupils were few, and it did not attract any extraordinary share of public attention. About eleven years after its formation, the patronage of the public enabled the managers to take on lease a plot of freehold ground in St. George's Fields, opposite to the end of Great Surrey Street, where suitable buildings were erected, within which the institution is still carried on. An Act of Parliament was obtained in 1826, which invests the committee with all the rights and privileges of a corporation, and they then purchased the freehold of the ground on which the buildings had been erected. These buildings were found insufficient for the purposes of

the establishment, and the committee purchased an adjoining plot of ground, upon which a new and enlarged building is erected. In 1800 there were only 15 persons in the asylum: the present number of inmates is 154,—78 males and 76 females. The inmates are "clothed, boarded, lodged, and instructed." The funds of the charity are ample. The receipts have seldom exceeded the expenditure. In addition to its annual subscriptions, donations, and legacies, it possesses a funded capital amounting to above 80,000*l.*, besides other available property. The articles manufactured by the females are, for sale, fine and coarse thread, window sash-line and clothes-line, fine basket-work, ladies' work-bags, and other ornamental works in knitting and netting; for consumption by the pupils, knitted stockings, household linen, and body linen. The occupations of the males are making shoes, hampers, wicker-baskets, cradles, rope-mats, fine mats, and rugs for hearths and carriages. These articles are sold at the institution, and it is said that the window sash-line is highly approved of by builders of the first eminence. The sale of articles manufactured during the year 1857 produced 815*l.*

An extraordinary change has taken place in the educational aspect of this establishment in the lapse of the last twenty-five years; its chief object at that time was instruction in manual labour; a few of the pupils were taught music, but the attempt to teach reading and writing had been abandoned from the unwillingness of the inmates to receive instruction. The recent reports contrast most favourably with those of former years. Not only are the pupils carefully instructed in the principles of the Christian religion, including the Holy Scriptures, and in vocal and instrumental music, but the following secular subjects are also well taught: namely, reading, writing from dictation, history, and geography; the emulating test of half-yearly examinations is also applied to this part of their education, and their inspectors in successive years (the Rev. J. D. Glennie and the Rev. W. Taylor) reported most favourably of the results. The former of these examiners says: "Both boys and girls are carefully and thoroughly instructed in the Holy Scriptures, Church Catechism, and Liturgy of our Church, and they have done justice to the instruction so received." In the boys' school, he was "much struck with the accuracy and rapidity with which the arithmetic, as far as Proportion and Practice, were performed." He congratulates the committee on the "efficient and satisfactory state of the school." The Rev. W. Taylor states that, "the first and second classes read steadily and carefully on Alston's system, showing that they did not read from memory, but made out the words as they occurred. The lesson on English history given by the school-mistress was very satisfactory." The examiner of the boys' school, at Christmas last, reported favourably as to their proficiency in reading, religious knowledge, ciphering, embossed writing, English history, and geography; a small class also worked some problems in Euclid for him in very good style. The chaplain's classes, held on four days in the week for special religious instruction, comprise some not in daily attendance at the school, and exclude those who have not yet learned the Catechism.

The report states that "few of those who study music attain proficiency as readers or workers, and that great difficulty exists in procuring situations for blind organists. It is therefore most important that before making application for a pupil to receive musical instruction, his friends should well consider whether they have a fair chance for securing for that pupil employment as an organist or teacher of music. If a pupil becomes a good musician and is able to command employment, he may do well, but if from lack of talent, or other causes, he is unable to find employment as a musician, or to gain a living at a trade, he will probably become a burden to his friends."

During the year 1857, a novel and most important feature was introduced into the school, by the formation of a band of about forty instrumental performers, who are instructed in secular as well as sacred music. The band contains about an equal number of wind and stringed instruments, and during last year they gave a concert at the Hanover Square Rooms, which cleared upwards of 120*l.* for the charity, after all the heavy expenses were paid. The report states, "that though an attractive feature of the school, it is difficult to assign the band a higher office than that of supplying to the pupils a most pleasant and welcome recreation in their leisure hours."

One other feature in the operations of this school, derived from the example of a contemporary institution, demands especial notice from the writer of this article, with whom the idea originated, and by whom it has been carried out for many years at the institution with which he is connected, namely, an inquiry at certain intervals as to the after-life of the pupils. Such an inquiry can alone truly show the results of education; it is applicable to all schools, but more especially to those where children are boarded and educated for a series of years, and in whose future welfare, those who have directed their education, known their failings, and their better qualities, cannot but be interested. To all schools of poor-law unions it ought at once to be applied. The managers of the London School for the Blind, have sent out since the year 1854, about 150 forms of inquiry respecting pupils who have left school, and are now at work in the country. The inquiries embrace the following points: their present mode of gaining a livelihood; their average weekly earnings; their power of reading; their knowledge of music, and the use they make of it; and their moral character. The result of these inquiries is very satisfactory;

about ten only have not been answered; the pupils, with rare exceptions, possess good moral characters for steadiness, diligence, and Christian principle; for the most part these returns are attested by the minister of the parish. Most of them retain, to a greater or less degree, their power of reading, though many of them are greatly in want of books. Few are able, even with the utmost exertion to maintain themselves fully; but most of them are doing what they can, and only twelve receive parochial relief. Those able to do most towards their support are workers at baskets and mats, but the greatest difficulty prevails in finding employment for the musical pupils, many of whom having been educated for musicians, are unfitted for work of any other kind, and spend most of their time in idleness. The importance of the industrial work taught in the school is thus clearly established.

The Hospital and School for the Indigent Blind of Norwich was originally established in the year 1805, first for that city, and subsequently (as the condition of receiving a donation) for the county of Norfolk also; but its doors have been opened to other parts of the kingdom since the year 1819. The blind in the more elevated sphere of society appear not unfrequently to have been the first benefactors of their more indigent brethren. Mr. Tawell, a blind gentleman residing in Norwich, first called the attention of that city and its neighbourhood to the wants of the blind, and with a munificence commensurate with his zeal, he purchased "a large and commodious house, with an adjoining garden of three acres in extent," which he offered as the basis of the institution. The plan of the Norwich Asylum was to unite a school for the young with an hospital for the aged. It designed to admit the young pupils at the age of twelve years, and to keep them in the school till they should have attained a sufficient knowledge of some trade, as far as this could be accomplished within three years, but under no consideration to keep them longer than that time: some however have been kept longer. With respect to the aged, the rules express that none shall be admitted who have not attained the age of sixty-five years. It appears from the account of the institution published up to the end of 1833, that from the establishment of the institution to that date, 153 pupils had been admitted and 48 aged persons: 77 had been discharged qualified to work for themselves; 12 had proved incapable of instruction; 4 had left the asylum without leave; 13 had been discharged for irregularity, and 16 at their own request; 43 had died, and 36 remained on the books. The expenses seem to have averaged about 1100*l.* per annum, and the income about equalled the expenditure. (We can give no more recent account of the Norwich school, as no answer has been received to our inquiries.)

The Asylum for the Blind at Glasgow is pre-eminently a manufacturing establishment, although much attention is also given to the religious and secular education of its inmates. It was founded by John Leitch, Esq., of Glasgow, who was himself partially blind; he bequeathed 5000*l.* towards opening and maintaining the institution. Since the opening of the asylum in 1828 to the commencement of the present year (1859) 334 blind persons have been admitted; of this number 103 are now in the establishment. The manufactures carried on are of sacks and sacking, twine, baskets, mats, mattresses, and knitting. The sales in 1858 produced 5960*l.*, which was about 870*l.* less than the previous year, and the value of the manufactured materials on hand was 2024*l.* The revenue is chiefly derived from the sales, and in this respect the Glasgow asylum differs from every other in the kingdom. It solicits no annual subscriptions, but depends entirely for its support upon donations and legacies; this source is precarious, and sometimes, as during the past year, a deficit occurs. By the system pursued in this asylum the blind are placed, as nearly as circumstances allow, on a level with other workmen. Many of the adults reside with their families in the city, and go to their labour at the asylum like other artisans. The superintendent purchases the raw materials for the manufactures, and keeps an account of the work each person performs, from which a statement of their earnings is made, and they are paid every Saturday. The male adults are allowed the same rate that other workmen have for the same kinds of work; if a man can make five or six shillings a week, he receives that sum for his weekly wages. At the end of every four weeks a statement of his earnings is made up from the work-book, and whatever he has earned over that sum is paid to him, and also an additional shilling a week as a premium upon his industry. If the amount which he ought to earn be not earned, or the work be bad, no premium is allowed. At the monthly settlement some of them will have several shillings to receive in addition to their regular wages and premiums. Ever since the regulations regarding wages have been adopted, a marked improvement has taken place both in the quantity and quality of the work produced. The blind workmen and their families receive the fruits of their labour with much pleasure. A spirit of industry is excited and kept up very different to their former habits, and an opportunity is thus afforded them of enjoying the blessings of home, which could not be cultivated when they were maintained within the establishment. A few elderly females are placed upon the same system; they work in the institution, but reside at their own homes. Females generally, above the age of eighteen years, are admitted as day-workers; they dine at the asylum and receive regular weekly wages; their apartments are separated from those of the males, and no intercourse

is permitted. Boys and girls from ten to sixteen years of age reside in the house, and in addition to attendance on their classes, they are taught to perform light works suitable to their age, till old enough to be removed into the regular workshops. The girls and female adults are under the superintendence of a matron, who also has the management of the sales. Several of the blind men are employed in calling on the customers of the asylum to deliver goods and to solicit orders. It is common for adults who reside in distant parts of the city to go to and from their employment without a guide, and no accident has ever happened to any of them. The usual branches of learning are taught to the young blind in the Glasgow asylum; the time devoted to school by both boys and girls is five hours a day on five days of the week, the chaplain being their teacher. The books used are printed in the Roman alphabet, which was arranged under the superintendence of John Alston, Esq., the former treasurer of the asylum, these books are printed on the premises, and are so numerous as to form a library in raised type. [BLIND, ALPHABETS FOR THE.]

There are three Asylums for the Blind in Dublin. The oldest of them, Simpson's Hospital, was opened in 1781; it was founded and endowed by a merchant whose name it bears, who was himself subject to a disorder of the eyes, and was also a martyr to the gout. The design of the hospital is to provide an asylum for blind and gouty men, the preference being given to those of good moral character, who have formerly been in affluent circumstances. About fifty persons partake of the benefits of this charity. It was incorporated in 1799, and its income is about 3000*l.* per annum.

The Richmond National Institution for the Indigent Industrious Blind is supported by subscriptions and donations; it was opened in 1809; the inmates, who are all indigent, are instructed in the trades ordinarily taught to the blind. At present the institution contains forty men and youths, who are lodged, maintained, and clothed there.

The Molineux Asylum is supported by subscriptions, by the profits of a chapel, and by charity sermons; it is solely for the reception of females, who are admitted at all ages. Those above fifty have here a permanent abode. The younger section of the establishment are lodged, clothed, and fed; and for a certain number of years receive instruction in those employments by which it is intended they shall earn their living. This asylum was opened in 1815, in the mansion of Sir Charles Molineux, Bart. This family has been among its most liberal benefactors.

In 1835, the Ulster Institution for the Deaf and Dumb, established at Belfast in 1831, admitted blind pupils also. This union of the two classes is a specialty in which this establishment does not stand quite alone. Between the two classes of inmates there is nothing in common, so far as their education is concerned; different senses being addressed, the process of instruction is essentially different, but when a medium of intercourse has been established between them by means of the manual alphabet, their being associated together is not without some points of interest.

On subjects of instruction the first place is given to religious training, and as a result of this, some of the blind pupils have become devoted and efficient city missionaries; one of them occupies an important position as one of the ministers at Brooklyn, New York. The other common branches of an English education also receive attention, and all who have voice and ear practise vocal music. About six hours daily are devoted to school, and two and a-half hours to manual labour. A large amount of the instructions conveyed is given orally, but the relief books printed at Glasgow, and those produced at Bristol are used by the pupils. Ninety-one deaf and dumb, and thirteen blind, are now in this institution.

The Limerick Asylum for Blind Females was established in 1835, chiefly through the instrumentality of the Dean of Waterford. It is capable of accommodating twenty inmates, but the funds of the institution do not afford support to this number.

The Yorkshire School for the Blind was instituted at York in memory of the late William Wilberforce. Its design is not so much to provide maintenance for the blind as to give them such instruction as may help them to gain a livelihood for themselves, attention being at the same time paid to their moral and religious instruction; their friends or parishes therefore contribute towards their support while they are in the institution. Those persons only are admissible who have lost their sight to such a degree as to be able at most only to distinguish light from darkness—those who have a capacity for instruction—those who are free from any dangerous or communicable disease—and those who have no vicious habits.

It is found from the recent reports of the Yorkshire school that less time is devoted to manual labour than in these asylums generally; but it must be remembered that the inmates are young. Music is much cultivated, and affords satisfactory evidence of its utility. With the view of forming a correct opinion on this subject, inquiries were instituted in 1856, as to the condition of the pupils who had left school. It was found that eleven had obtained situations as organists, and were enabled to maintain themselves fully; four others were engaged in teaching music and tuning instruments, and thus maintained themselves to a great extent. In addition to those who had left school, there were six male adults and one female still resident in the school, who were filling organists' situations. The results of these inquiries as to other industrial pursuits were less satisfactory, and the inference drawn was, that

music was the only really remunerative pursuit for the blind, under the present arrangements of the Yorkshire School.

Another hint of considerable value may be drawn from the series of reports of the Yorkshire school. A year or two ago, a sergeant was engaged to drill the pupils, and it has been found of the most essential benefit to them. One of the pupils remarked, that he walked with much greater confidence since these exercises had been practised, and this feeling will be one of general experience; it may therefore be commended to the attention of other establishments for the blind. The superintendent of the Yorkshire school is W. D. Littledale, Esq., who is himself blind, and whose whole heart seems to be given to the improvement of the school. The general branches of education are taught, and books in the Roman type are preferred. The Rev. W. Taylor, author of the 'Tangible Euclid,' formerly devoted to the interests of this school, has left York; his attention, however, is still directed to the welfare of the blind. The number of pupils in the York school is sixty.

Henshaw's Blind Asylum, at Manchester, was opened for the admission of inmates in 1838. An endowment of 20,000*l.* was left in the year 1810 for the support of such an asylum, by the will of Thomas Henshaw, formerly of Oldham. Notwithstanding the large accumulations arising from this source, no part of Mr. Henshaw's bequest could be appropriated to the purchase of land for such asylum, nor for the erection of a suitable building; and the sum of 10,000*l.* was subscribed by the inhabitants of Manchester for these objects. The building, together with one in exact correspondence, for the education of the deaf and dumb, was erected at Old Trafford, and the approximation of the two charities was rendered closer by a subsequent agreement of the respective committees for the erection of a chapel in the space between the two buildings, thus connecting them as consistent parts of one uniform structure, in the English Academic style of architecture. The object of the asylum is not only to afford a home to the impotent and aged blind, but also "to maintain and afford such instruction to the indigent blind of both sexes capable of employment, as will enable them to provide, either wholly or in part, for their own subsistence, and to promote the employment of, or to employ, blind persons." The training of the inmates is therefore both intellectual and industrial, but it is not stated in the last report how the school instruction is carried on. It may be inferred that the books in Roman type are used; the late governor, Mr. Hughes, emphatically says, "I would discourage all systems of embossing which could not be read and taught by seeing persons." The articles manufactured are more various than in the generality of these asylums. The number of inmates in 1858 was seventy-five.

The Royal Victoria Asylum for the Blind, at Newcastle-upon-Tyne, was founded in the year 1838, to commemorate the coronation of Her Most Gracious Majesty the Queen; its object, as expressed in its first regulation, "being, to afford to the blind an elementary education, and instruction in those branches of trade and manufacture which shall be found suited to their capacity," as well as to afford them spiritual instruction. During the existence of the asylum, 115 pupils have been received into it, of whom 37 are now under its care, 22 of whom are males, and 15 females. Pupils are received into it from the four northern counties of England. The works of the inmates are of the usual kinds; the forenoon of each day is given to manual labour, the afternoon to music and general education. The relief books in Roman capitals are preferred.

The West of England Institution for the Blind was established at Exeter in 1839. It contains twenty-five inmates of the two sexes, all of whom are taught the usual branches of education, including music, and some to make baskets, mats, rugs, sash-line, &c. Sixty-two of its boarders and forty-one day pupils have quitted since its commencement. Its income is derived from the usual sources, namely, subscriptions, donations, board of pupils, and sale of work. Lucas's raised alphabet is used, and it is one of the regulations of the committee that "the system of teaching to read shall be that by means of the raised stenographic character."

An Institution for the Blind and Deaf and Dumb was formed at Bath about the year 1840. A considerable number of pupils of both these classes have been instructed under its care; and at the date of the last report (1858) it contained fifty-one boarders, of whom twenty-eight were deaf and dumb, twenty blind, and three partially blind and deaf and dumb; it also extends its benefits to day and Sunday scholars, of whom it numbers twelve deaf and dumb, and four blind. Miss Elwin, of Bath, has taken a benevolent oversight of this establishment, from its first commencement to its present mature condition. A "Home" for blind girls has also been formed, for those who, having passed the allotted period of five years' instruction, have no friends able to provide them with a suitable place of residence. The training which the blind children receive is both intellectual and industrial; the former comprehends reading, on Lucas's system, arithmetic, geography, music, and singing; the latter is confined to basket-making. The morning hours are devoted to labour; the afternoon to mental and religious instruction. In the "Home," the greater part of the day is spent in basket-making, which contributes in part to the support of the establishment, and the inmates are frequently read to while they are at work.

An asylum for the young blind was established in Brighton in 1841,

the pupils not to be under six, nor exceeding twelve years of age. It is designed for the town of Brighton and the diocese of Chichester, with power to the committee to receive candidates from other localities. This school is under the management of Mr. Moon, one of the inventors of raised characters, to whose system attention has been directed in the article, BLIND, ALPHABETS FOR THE. The school contains twenty-one pupils.

The Midland Institution for the Blind is situated at Nottingham, and comprehends the counties of Nottingham, Derby, Leicester, Lincoln, and Rutland. Its chief object is the education and training of the younger part of the blind community. The age of the inmates varies from nine to twenty-four. The usual intellectual and religious instruction is imparted, and the trades are much the same as those followed in other establishments; it is thought some new trades might be profitably commenced, and, among others, brush-making. No male pupils are allowed to commence work till they can read; but the female pupils, from the day of their admission, spend half the day in their work-room, to be instructed by the governess in sewing and knitting, and the other half in school. The teachers, except the governess, are all blind. Lucas's system of raised type is generally adopted, but some of the pupils can read Moon's and the Roman books. The schoolmaster, who is blind, reads books on six different systems, but gives the preference to that of Lucas. In arithmetic the pupils are considerably advanced, and can work and comprehend fractions and decimals; the arithmetical board and pegs differs from that used in the institutions of Scotland. The admission of day-pupils free on the recommendation of a governor is a good feature in this establishment, though it is not confined to it. Such pupils may remain as long as there is room for them; and when they have acquired a trade, so as to make articles sufficiently well for sale, they are employed and paid journeyman's wages.

The General Institution for the Blind, at Edgbaston, near Birmingham, was commenced in 1846 by private benevolence, and adopted by the public the following year. Its income is derived from the usual sources, namely, subscriptions, legacies, donations, payments on behalf of pupils, sale of work, &c. The present number of pupils is fifty-nine, and they are classified both for school and labour, so as to give all the advantages suitable for their age. The school teaching comprehends reading, spelling, arithmetic (peg and mental), geography with the aid of globes and maps, and object lessons. There are upwards of sixty maps, and one is used by every two pupils. These maps are made by friends of the superintendent, and have been much admired by the conductors of different institutions. In music the pupils practise from one to three hours a day, according to their progress and talent. Church music only is taught. Four of the pupils, from sixteen to eighteen years of age, have obtained situations as organists, at salaries varying from 20*l.* to 30*l.* a year. In reading by the touch, Moon's system is used. This institution has the advantage of an indefatigable treasurer, Thomas Goodman, Esq., whose exertions for this and other charities which have for their object the relief of human suffering, are beyond all praise.

The title of the next institution to be noticed would lead to the supposition that a new sphere of operations was to be brought under observation. It is called "The London Society for Teaching the Blind to Read." It is situated in Avenue Street, Regent's Park, and it has been in existence twenty years. The indications of its distinctiveness are few, and chiefly relate to its plan of admitting pupils, and its adhesion to Lucas's system of reading, in which it has published the whole of the Scriptures and many other works. The usual kinds of school-instruction and of labour are taught to the pupils, of whom there were sixty in the institution in 1858. As an auxiliary in the cause of the blind, it must prove beneficial. According to its rules, it receives free boarders on the nomination of donors of 250*l.* in one sum, and by election of subscribers for three years; indigent boarders on payment of 15*l.* per annum; music being an extra charge of two guineas per annum. Male adults are not lodged in the house, and have to pay 2*s.* a week for lodgings in the neighbourhood. Day-pupils are admitted free on the recommendation of a subscriber.

The establishments of which some account has been given are not the only means carried on in these days for alleviating the condition of the blind, and increasing their means of happiness. Other appliances are also in action. Although blindness cannot be considered as the heaviest of human calamities, it is one which claims the most immediate sympathy and prompts the universal desire for its relief. Societies have been established for teaching the adult blind to read; many of which are connected with Moon's system. Mr. Moon, himself blind, commenced his printing labours at Brighton more than ten years ago; his books are not only largely used in that place, but in many other provincial towns, which have been supplied with home teachers, and in which lending libraries have been established. One of these societies has been formed in London; from it have emanated two lending libraries of Moon's books; and its first report (1857) states that in eighteen months 236 blind pupils had, for longer or shorter periods, been under instruction; of these 117 had learned to read, of which number 53 were above 50 years of age, and 8 were from 70 to 75. It would be very ungracious to cast a shade of doubt on the statements put forth of the rapidity with which the art of reading was acquired by these aged persons through the medium of touch; yet

there must be some fallacy, the facilities given by a previous knowledge of reading and spelling must have existed, for even aged persons with all their senses cannot learn to read in *three lessons*! If they could read and spell before they lost their sight, or if they had learned to read on some other system previously, the wonder ceases to some extent. The work is a good work, and requires nothing marvellous to sustain it. The London depository for the books on Moon's system is at 25, King William Street, Trafalgar Square.

In Euston Road, near St. Pancras Church, a thoroughly practical work is going forward for the amelioration of the condition of the industrious blind. It is known as "The Association for promoting the General Welfare" of this class of people. It has been in operation about five years; it provides means of industrial employment for those who have not been so fortunate as to obtain admission, and consequently instruction, in asylums; it supplements the education of those who have had this advantage; it teaches trades to those who have learned none, and finds a market for the work, thus enabling many of the adults so taught to support their families; it supplies regular work to many at their own homes; it finds workshops for others within the precincts of its own humble establishment. At present it affords employment to sixty-seven blind men and women, some of whom have been withdrawn from begging and destitution, and it has a list of upwards of ninety candidates, who desire to be put into a similar mode of earning their bread, and who will be gratified in their desire when the public favour to the establishment demands more articles than the present workers can supply. The town traveller and the porter of the establishment are both blind, yet they traverse crowded thoroughfares, and walk long distances, self-dependent, or trusting on the good-will of strangers for information and direction. Blind agents are also employed in selling the goods manufactured in several towns in different parts of the kingdom. This society is assisted by subscriptions and donations, for from the waste of materials and the slowness of the learners it cannot be self-supporting. The foundress of this truly beneficent association is Miss Gilbert, a daughter of the bishop of Chichester, herself blind, and a contributor of 2000*l.* to its endowment fund; for more than a year she worked the plan alone. Its control is now made over to a committee of influential men, and it may be hoped that the practical wisdom which devised its plans will be carried out with that ability which will ensure success commensurate with its object. The above account of this excellent charity is abridged from an article in 'Household Words.'

Charities for the blind also exist which grant annuities under certain conditions. The oldest of these is Hetherington's, it was established in 1774; the other is the Blind Man's Friend, established by Mr. Day; in October 1858 there were 2500 applicants waiting for this charity.

It appears that voluntary benevolence, together with the provision made under the Poor Law Act, by which the blind may be maintained during education in the asylums established, will in the course of time provide for the training in industrial pursuits of all the blind who require such aid. Great has been the progress towards this end during the last twenty-five years. The intellectual training will doubtless keep pace with the industrial, now that the public are aware how much can be done. The increase of books is also certain, with so many competitors for public favour in the field. It has been already stated that the Scriptures are published in four distinct systems. Attention should now be directed to the publication of a good reading-book on secular knowledge, the subjects of which should be consecutive, progressive, and systematic. The republication of some existing school-book is more desirable than the preparation of an original work for many reasons; but it should not be a miscellaneous collection of lessons without plan or arrangement on every variety of topic in succession, tending to bewilder and excite rather than to satisfy the mind. The moral tone of the inmates of the various schools is a subject of special mention in many of the accounts we have received, yet it is thought some advantages would arise from a stricter classification, so as to prevent the young blind from mingling with the adults and the aged. In the workshop the restraint which is necessary for the young is irksome to the older inmates, and the exercise of all their good principles is requisite to prevent the rising of a rebellious spirit. Separate establishments for children and adults, or an entire separation in the same building seems desirable. At Norwich there is such a provision. The inmates of Henshaw's asylum, at Manchester, are not restricted as to age, and are in for life, but the old are not separated from the young, consequently they cannot have that quietude which age and infirmity require. In one or two of the establishments drill and gymnastics receive attention. These physical exercises are highly commended by Dr. Blacklock, as giving confidence, and they should be universally cultivated among the young blind. It is a question worthy of some consideration by the managers of our asylums, as to what extent blind teachers can be eligibly employed in the various departments. As far as the communication and transmission of ideas are concerned, the blind teacher may possess some advantages over the seeing one, yet circumstances arise in which the evils attendant on the want of sight counterbalance these advantages. In the *school-room* we find bad habits and positions of the body; in the *workshop*, badly shaped articles and waste of materials; in the *musical department*, wrong positions of the hands, and a bad system of fingering, with

an awkward attitude and distortion of the countenance in singing. It cannot be expected that blind teachers should be aware of these things. An exact record of the after-life of all the pupils should be kept in every asylum for the blind. Such records are the result of the care and attention of teachers, and of the application and attainments of pupils, and the blind themselves should know that such an account of their future course will be recorded, and published for the satisfaction of those who generously support these establishments for their benefit.

The number of blind men who have become eminent is large; for some account of them we must refer to the work of Dr. Guillié on the 'Instruction of the Blind,' to blind James Wilson's 'Biography of the Blind,' to the first volume of the 'Pursuit of Knowledge under Difficulties,' and to Dr. Kitto's 'Lost Senses—Blindness;' in these works we read of philosophers, mathematicians, divines, musicians, rhetoricians, lawyers, historians, poets, naturalists, road surveyors, mechanics, travellers, and even sculptors, who laboured under the infirmity of blindness.

The addition of deafness to blindness seems almost to shut out a human being from the external world. It is difficult to conceive how the mind of a deaf, dumb, and blind person can be occupied—much more difficult to say how it can be improved and educated. Yet there are many cases of this three-fold deprivation known, and there are always one or more such instances undergoing instruction in our blind or deaf and dumb institutions. The case of *James Mitchell*, the son of a Scotch clergyman, which was investigated by Dugald Stewart, Mr. Wardrop, and Dr. Spurzheim, is the best known; *Julia Brace*, a pupil in the asylum for the deaf and dumb at Hartford, Connecticut, is another instance of the same kind; *Victorine Morisseau*, a pupil in the Imperial Institution for the deaf and dumb of Paris, was another sufferer under this accumulated calamity; *Laura Bridgeman*, a pupil of Dr. Howe, in the Boston Asylum for the blind, is not only defective in these senses, but also in that of smell. She has had companions in the same affliction in *Oliver Caswell* and *Lucy Reed*. *Edward Meystre*, of Lausanne, is another case of the kind. He too has met with an instructor. Each of these instances is a history in itself of a mind sealed up, but unsealed by the indefatigable zeal and skill of their respective teachers. Space is not allowed us to go into the manifold processes which patience and enterprise invented for conquering the difficulties which interposed between these minds and the world without. The results are not merely satisfactory, they are marvellous.

The blind are not a moody or a discontented class—fun, frolic, and mischief are as inherent in them as in others. We extract a few anecdotes from an interesting pamphlet published some years back by Mr. Anderson, who passed many years of his life as teacher and superintendent in the several asylums of Edinburgh, York, and Manchester, which show their vivacious habits.

"Romping, jumping, laughing, and screaming, are as delightful to them as with boys and girls who see. The cross-bow, bow and arrow, trundling each other in a wheelbarrow, spinning tops, and to those who have a glimmer of light, called 'blinkers,' marbles, and a kind of cricket, all afford ample amusement, while there is no want of the usual boyish plotting and mischief. The girls also enjoy their play-hours very much, and contrive to stand in as much need of the needle as their more favoured sisters of sight.

"A girl at York took up a book lying beside me, turned up her face towards the gaslight above my head, and playfully observed, as she whirled over the leaves, 'Dear me, sir, what bad gas this is, I can't see to read a word by it!' The same girl standing near the fire, heard a companion trying to decipher some of the letters of the book in relief, 'Let me see,' said the latter, 'what's this—bit, ter; bit—what does that mean?' 'Sit a little nearer the light, my dear,' said her fireside companion, 'I know you don't see very well, Jane.' The tone of this indicated genuine playful mischief.

"A young man at the Edinburgh asylum, born blind, was at all times the essence of cheerfulness. He was one of our most correct 'messengers,' and a good collector of accounts, of which from the amount of our annual sales, we had many. He, as well as several others, could easily take from four to eight of these at a time. Coming along the passage whistling—he was always whistling—he began to grope about for his hat, which, not finding on its usual peg, he cried to a companion, whose foot he heard not far off, 'Willie, come here, man, and look for my hat, ye see better than me.' The one was as blind as the other.

"It is a remarkable fact that the blind scarcely ever hurt themselves, either against furniture, or in play. At Edinburgh they were constantly walking about the crowded streets. There were four or five 'messengers,' whose business it was to carry home all the goods sold—baskets, mattresses, rope-mats; and not only did they do this with the greatest exactness, but they were daily in the habit of going to all parts of the city, Leith, Portobello, and environs, to take measurements for bedding. I have many times had the dimensions of two, and even three beds brought to me—all on memory—with a precision not exceeded by the most expert workman, including the exact allowance of so many inches to be cut out for the bed-posts.

"I had occasion one evening, at Edinburgh, to send out one of these blind men with a mattress. I gave him the bill with it, that he might

receive payment. He returned with the account and the mattress too. 'I've brought baith back, ye see, sir,' said he. 'How so?' 'Indeed, sir, I didna like t'leave't yonder, else I'm sure we wad ne'er see the siller—there's no a stick of furnitur' within the door!' 'How do you come to know that?' 'Oh, sir, twa taps on the floor wi' my stick soon tell't me that!' Having to send the same man to Portobello, toward evening, I warned him (rather inadvertently!) that if he did not make haste it would get dark. 'My word, sir,' said he laughing, 'I wish I had a shillin' for ilka time I've been in Portobello i' the dark.'

"As a body, the blind are the most habitually cheerful of mankind. How it comes to be so I cannot tell, and I have no wish to theorise. I cannot designate the blind, as is almost universally done, 'the unhappy,' 'melancholy,' 'pitiable,' and so on. I know nothing more erroneous, or more opposed to the feelings of by far the greater majority." So says Mr. Anderson in his 'Observations on the Employment, Education, and Habits of the Blind,' and he was a man of large experience among them.

BLINDAGE (called also BLIND), is a term employed in military art to any temporary construction made to secure artillery against the effects of ricochet and vertical fire, or the troops against the effects of shells; it consists usually of stout timbers, covered with fascines, earth, and sodwork, and in fact is the temporary expedient for casemates.

In fortresses, when regular casemates have not been constructed for the protection of the ammunition and provisions, or of the soldiers while not employed in active duty, covered buildings of a temporary nature are formed for those purposes at, or previously to, the commencement of a siege. The simplest are such as are made against the side of some strong wall within the place, or, which is preferable, against the revetment of the counterscarp, in a dry ditch, on any of the fronts not exposed to the fire of the enemy. These inclined blindages consist, when timber is plentiful, of thick beams placed close together, and leaning against the wall at an angle of 45°, one extremity of each resting on a sleeper laid in the ground: in other cases the beams are placed at intervals from each other; over them are laid horizontal joists close together, and the whole is covered to the required thickness with fascines and sods when they can be procured; the entrance is at one extremity of the building. This kind of blindage is also constructed to cover the miner employed in piercing the escarp wall of a rampart when the breach is to be formed in it by the explosion of a mine.

A blindage is sometimes formed independently of any wall, by planting the timbers in the ground in inclined positions so that their upper extremities meet together in a ridge, when the building resembles the roof of a house, and the whole is covered with fascines and sods. But generally an area is enclosed by a wall made of strong palisades planted vertically in the ground, the roof being formed of timbers disposed horizontally and close together, above which comes the bed of fascines and earth. For a small magazine the inclosing wall may consist merely of gabions filled with earth; the area being covered as before.

A blindage is said to be bomb-proof, when, from the thickness of its roof, it is capable of resisting the shock of loaded shells; and splinter proof when merely capable of securing persons within it against the fragments resulting from the explosion of such shells.

The French give the name of blindage to any building already existing in a fortress, when a shell-proof covering has been made to it in place of its proper roof; this cover is obtained by placing girders over the interior, and overlaying them with joists and earth. And when the walls are not sufficiently strong they should be cut down to a convenient height, and covered as before. On the exterior of the building leaning blindages may be formed as above described, and sometimes the whole of the exterior walls are protected in the same manner, leaving only the entrances, which are generally opposite to the piers between the doors and windows, where some of the inclined timbers are omitted: but occasionally the walls and roof are merely strengthened and supported by shoars or inclined props firmly fixed below in the ground, and above resting against and supporting the extremities of the girders. For these kind of blindages such buildings should be selected as have their lengths in the probable direction of the enemy's fire, to avoid as much as possible their being exposed to direct fire.

To secure some of the artillery on the ramparts of a fortress against the effects of ricochet and vertical fire, shell-proof blindages are formed, by planting in the earth strong palisades vertically six feet on each side of the gun, extending from the interior slope of the parapet about 24 feet to the rear, across the terreplein or upper surface of the rampart; these carry a roof made with timbers, which extending forwards covers the embrasure as far as 9 or 10 feet from its neck, or interior extremity. These blindages are open towards the rear, and the guns fire through the embrasures as usual. The under side of the timbers of the roof is about 7 feet above the terreplein, and is covered with a double layer of fascines and earth above that to a thickness of about 5 feet. It has also been recommended to form the blindage in the thickness of the parapet itself, the roof being well covered with timbers, fascines, and earth, open to the rear, but the exterior closed by a number of stout timbers placed horizontally, so as

to make a wall 4 feet thick, through which the embrasures are cut, like the portholes of a ship.

In the attack of fortresses, when the trenches of the besiegers become subject to a plunging fire from the place, they are protected by blindages; these are formed by fixing rectangular frames of timber, commonly called great gallery frames [MINES], vertically along the two sides of the trench, and placing similar frames or any timbers across the trench on the top of these, to carry the roof which consists of fascines covered with earth or raw hides.

Blinded trenches of this kind were formerly much used by the besiegers to protect their descent into the ditches of fortified towns; one of this kind was executed by the French for that purpose when they besieged Danzig in 1813.

BLINDNESS. [EYE.]

BLISTER, a term used to express a bladder or vesicle raised upon the skin by the application of some external irritating substance, and also to denote the external application itself by which this effect is produced. The terms *vesicatory* and *epispastics* are also frequently given to the external application or other preparation. The substance usually employed as a vesicatory is the powder of the Spanish fly. [CANTHARIDES.] The powder of the cantharides is mixed with lard and wax, so as to produce a plaster of tolerably firm consistence, which is spread on leather and applied to the part for the space generally of from ten to twelve hours. The first effect of the application of the blister-plaster to the external skin is to produce a sense of tingling and heat; this is followed by redness, commonly attended with pain, and subsequently there takes place an elevation of the cuticle into a vesicle or bladder, which contains a fluid resembling the serum of the blood. On the effusion of this fluid the redness continues for some time; the serum gradually thickens, and at last is changed into a whitish curdly substance, under which new cuticle is formed, though occasionally the serum is converted into proper purulent matter, the blistered part successively contracting, until the whole wound is healed. Sometimes coagulable lymph is effused.

The effect of the application of a blister is the production of a true inflammation over the whole surface of the skin with which the plaster is in contact. The effusion of a serous fluid from the excited capillary vessels of the skin is one of the ordinary phenomena of inflammation. The formation of the bladder or vesicle is occasioned simply by the elevation of the cuticle from the true skin, by the fluid poured out from the cutaneous capillary vessels. The inflammation induced by the blister is the effect of a powerful stimulus applied to the cutaneous blood-vessels and nerves.

The extent of the inflammation is usually confined to the surface in actual contact with the blister; it is comparatively rare that any degree of irritation is communicated to the general system; and yet the relief afforded is often so great, that the effect appears disproportioned to the cause, a small external inflammation mitigating or removing an extensive and severe internal inflammation. Much discussion has taken place as to the principle on which this relief is afforded, and the real mode in which the blister produces the benefit observed to result from it is not clearly understood. It is certain that the chief benefit results in the state of what is termed local inflammation; that is, when the inflammatory action is confined to a single organ or to a part of an organ. In order to understand the true nature of the change effected in the part relieved, it is obviously necessary to understand the true nature of inflammation. [INFLAMMATION.] It may be here stated, that in inflammation artificially induced with a view of observing the phenomena that take place in this process, the blood-vessels of the part inflamed are seen to enlarge and to become preternaturally distended with blood, while the motion of the blood in such vessels is either very much retarded or ceases altogether. The knowledge of this fact enables us to understand, in some measure, the action of a blister. The application of a powerful stimulus, such as that caused by the Spanish fly, in the neighbourhood of vessels relaxed and over-distended with blood, relieves such vessels by depriving them of a portion of their blood, and by consequently removing the state of over-distention. For the stimulus applied to the skin determines a large quantity of blood to the cutaneous vessels under the influence of the vesicatory; this blood is derived from the blood-vessels of the parts in the immediate neighbourhood of the vesicated skin, from the blood-vessels of the inflamed part among the rest; and the blood-vessels of the inflamed part being relieved from the preternatural quantity of blood that distended them, return to their healthy action.

Another reason has also been assigned for the relief afforded by the application of blisters. It is observed, that when a morbid action exists in any part of the body, it may sometimes be removed by exciting a morbid action of a different kind in the same or in a neighbouring part. It is assumed that two morbid actions of different kinds cannot go on in the same part at the same time; hence the surgeon and physician, when they observe diseased action going on in a particular part of the body, induce, as near to that part as possible, another action of a different kind, frequently with the effect of lessening or altogether stopping the former morbid action. Now one of the instruments most commonly employed to excite this new action is the blister, and the excitement of such action, on the principle just stated, is conceived to be one mode in which the blister, as a general remedy, proves beneficial.

But whatever be their mode of operation, the fact is certain that blisters often prove more extensively beneficial than could have been anticipated from the limited surface on which they act, and from the very slight discharge they induce. Though, as already stated, they are most beneficial when the inflammation is seated in a particular organ or in part of an organ, yet they are by no means without advantage in cases in which the system is generally and deeply involved; but then benefit can only be obtained from them after bleeding, purging, and other evacuations have lessened or subdued the general action of the system. In this case they often complete and render permanent the benefit derived from the preceding remedies.

For the reason already assigned, they are most commonly employed (after remedies that act powerfully on the general system) in pneumonia (inflammation of the lung), in gastritis (inflammation of the stomach), in hepatitis (inflammation of the liver), in phrenitis (inflammation of the brain), and so on; but there are diseases of the nervous system in which they are decidedly useful, as in spasmodic affections attended with pain but without inflammation, in the paroxysms of angina pectoris and of spasmodic asthma, in epilepsy, catalepsy, hysteria, paralysis, &c.

Benefit is sometimes derived from the application of blisters through their immediate and direct action as stimulants, chiefly in full habits, in which languor is the consequence of over-distension. In these cases they excite the whole system, and produce an exhilarating effect. A gentleman once highly distinguished at the bar, and of brilliant convivial powers, always applied a blister when he wished to shine in either sphere, and the effect was produced as soon as the warmth in the part began. Many persons, even though they feel acutely the pain produced by blisters, declare that the relief from the previous languor counterbalances all their sufferings.

The application of a blister is sometimes successfully employed as a means of directly lessening pain. The excitement of one pain diminishes another: hence the relief afforded in tooth-ache and other painful affections. Although in general blisters relieve more pain than they give, yet in some irritable skins and in some irritable states of the system they produce occasionally extreme excitement and suffering. By the previous employment of the appropriate remedies for soothing the irritable state of the system, the beneficial effect of blisters may be obtained even in constitutions thus predisposed to irritation from the operation of this remedy, which constantly produces good or bad effects, just as its application is well or ill timed. One painful affection occasionally induced (strangury) is effectually relieved by an anodyne injection thrown into the rectum, consisting of four or six ounces of thin tepid gruel, with thirty or forty drops of laudanum.

BLOCK (German, *Blöcke*; Dutch, *Blokken*; Swedish, *Skepps-block*; French, *Poulie*; Italian, *Bozelli*; Spanish, *Motones*; Portuguese, *Moutões*; Russ, *Bloki*), an instrument generally made of wood, but sometimes of iron. It is much employed in the rigging of ships to give facility to the raising or lowering of the masts, yards, and sails, and for such other purposes as require and admit of the application of the pulley—a block, as used on board of ships, being simply a pulley in the greater part of its modifications. One description of blocks, to which the name of dead-eyes has been given, is not a pulley, being unprovided with sheaves. These dead-eyes are used for setting up and fastening the shrouds and other standing rigging of the ship, while sheaved blocks are used for the running rigging. The more usual form of blocks of both descriptions is that of an oval spheroid, flattened at opposite sides. Dead-eyes are made out of one piece of wood, pierced with the requisite number of holes, through which the standing rigging is passed. Single-sheaved blocks are made up of three distinct parts, namely, the shell, the sheave, and the pin which serves as an axis round which the sheave revolves. Some blocks are made with two, and others with three, and even four sheaves, which all revolve on the same pin or axis, and consequently parallel to each other, in separate chambers formed for that purpose in the shell of the block. Blocks in all their varieties are used also for the purpose of raising weights in every department of mechanics and constructive operations.

The construction of blocks would seem to be a very simple operation, such as any man accustomed to work in wood could perform with facility and accuracy; but this in practice is not found to be the case, as the parts must be fashioned and fitted together with the greatest possible accuracy, in order to insure their easy working when put together—a circumstance of considerable importance in the management of a ship. For this reason, block-making has long formed a substantive branch of manufacture, and is carried on either by itself, or in conjunction only with mast-making.

About 1801, Mr. Brunel succeeded in completing a perfect working model for constructing both the shells and sheaves of blocks. This model being submitted to the inspection of the Lords of the Admiralty, the invention was at once adopted by government, and Mr. Brunel was engaged to superintend the construction of the requisite machinery at Portsmouth, upon a scale sufficiently large for making blocks to supply the whole naval service of the country. The completion of this machinery occupied nearly six years, and was not brought into full operation until September, 1808; but similar machines are now in use at Chatham and elsewhere.

The assemblage of machines devised by his inventive genius for the

formation of the blocks employed in raising burdens, and particularly in the important service of moving the rigging of ships, contains so many ingenious processes for gaining the proposed ends with the utmost accuracy, and, at the same time, with the least possible labour, as to justify the opinion that it constitutes one of the noblest triumphs of mechanical skill; and, in this article, it is intended to give a brief description of the principal parts of which it is composed.

The machines may be said to consist of many saws and lathes; by these the work is performed, from the operation of cutting up a log of timber, to that of polishing the pins on which the pulleys turn; and motion is communicated to all of them by a single steam-engine.

A straight saw worked backwards and forwards, horizontally by the engine, cuts off in succession different portions transversely from the log of timber (elm) which, for this purpose, is made to rest on a table or low bench; the portions cut off being of the proper lengths for the dimensions of the intended blocks. For the smaller logs a circular saw is used; it cuts the tree transversely, and consequently its plane is perpendicular to the axis of the latter: the saw is capable of being raised vertically, or moved horizontally at pleasure, in order that it may be made to enter the wood above or below, or on either side.

After the log has been cut in slices, the latter are brought to what is called the ripping saw: this is circular; and its plane standing vertically, in part above the level of the table, it serves to cut the slices into rectangular parallelepipeds. In this state the wood is brought to the boring machine, which may be thus described (the lower figure representing the plan, and the upper a side elevation):—

The rectangle *ABCD* represents the surface of a strong table, on which is fixed an iron frame *E* having three legs; within these the parallelepiped *F* is placed between three screw-heads, two of which appear at *a a*, and it is rendered immoveable during the operation by means of the screw *b*; this last being turned by the iron bar *GH*. *cd* is one of the borers, which turns on its axis by means of the pulley *K*, the latter receiving motion from the engine: this borer rests on the frame *M N*, which is capable of being moved towards the frame *E* by pressing on the end *P* of the lever *PQ*, so as to turn it about the pivot *Q*. *hk* is another borer, which turns on its axis by means of the pulley *R*, the latter also receiving motion from the engine: this borer rests on the frame *S T*, which is capable of being moved towards the frame *E* by pressing on the handle *UV*, so as to turn it about the pivot *V*.

The former borer makes the hole for the pin on which the sheaves of the block are to turn; the other merely makes a perforation at a spot which is to form one extremity of the mortise intended to contain a sheave. If the block is to contain two or three sheaves, the borer is to make as many perforations, the frame *S T* being capable of moving in a direction parallel to *BD*, in order that the point of the borer may be placed where the required perforations are to be made.

A remarkably ingenious machine is employed to cut the mortises in which the pulleys are to turn; and it is hoped that the following cut and description will suffice to render the process intelligible. *AB* is a representation of the horizontal surface of the table or stage on which the block is placed; and the diagram above it exhibits a side elevation of the acting part of the machine, the pillars and braces which support it being omitted, as they would have concealed, in part, the apparatus. *aa* is a frame made to contain the block *b* which, in the diagram, has but one mortise; the block is tightly fitted in this frame by means of the screw *s* at one extremity, and the frame is capable of being moved along the stage from *s* towards *tt*, as much as the whole length of the intended mortise. The great screw *CD* is fixed at one extremity to

the frame which contains the block, and works in a concave screw, which is cut in the transverse piece *tt*, the latter being fixed to the table or stage.

EF is an axle which terminates with a crank at *E* and carries at the

opposite extremity the fly-wheel *GH*, the revolving motion being communicated from the engine by a strap passing over the cylinder *K*. The circular motion of the crank at *E* produces by means of the bent rod *L*, which turns on a joint at *d*, a reciprocating motion vertically in the rod *e* which passes through a collar at *f*: to the lower part of this rod is made fast the steel chisel *g* by which the mortise is to be cut; and it may be easily understood that, if two or three mortises are to be cut at the same time, as many chisels may be fixed, in line, parallel to one another, in a frame which is carried by the rod *e*. On the screw *CD* is a toothed wheel *h*, and below it is a small wheel *k* which can be turned round by means of the handle at *m*, and thus a small motion may be given to the frame *aa* in order to bring the hole previously bored in the block vertically under the chisel *g*. The axle *EF* carries an eccentric wheel *n* (seen edgewise), on the circumference of which rides one extremity *p* of a bent lever *pq*, the lower branch of which lies tangentially on the top of a ratchet wheel *r*: the inferior surface of this branch has a notch, the sides of which, by the movement of the eccentric wheel, are made to act on a tooth of the wheel *r*; and thus, the axle *CD* being turned, the frame *aa* is moved a little way towards the cross-piece *tt*. This movement always follows immediately after the chisel has made a descent, and thus there is presented a new part to be cut out from the block. Since the chisel goes quite through the block at each descent, and the movement is very rapid, the mortise is quickly made.

The extremity *q* of the bent lever *pq* rests upon a lever whose fulcrum is at *v*, and this rests at *w* on the bent lever *wxy*, whose fulcrum is at *x*, and when by the motion of the frame *aa* the notch at *y* falls over the extremity *z* of a projection on the side of the frame, the notch in the branch *q* is lifted above the top of the wheel *r*, and the mortise being completed, the frame with the block moves no further. The cylinder *K* is hollow, and within it, upon the axle *EF*, is a cone which, while it turns with the axle, is capable of being moved backwards or forwards on the latter by means of a lever not shown in the cut: when this cone is thrust as far as it can go into *K*, the friction is great enough to allow the axle to be turned with the fly-wheel and cylinder; but, on drawing the cone towards *E*, its surface is disengaged from the interior surface of *K*, so that the axle *EF* no longer moves with the fly-wheel. It is while the axle ceases to revolve that the mortise block is removed, and one on which the operation is to be performed is put in its place.

The block is subsequently submitted to the action of a circular saw, by which the corners are cut off, and it is made to assume the form of an octangular prism; in this state it is removed to what is called the shaping machine, in order to be reduced to the requisite figure.

The shaping machine consists of two wheels connected together and turning on the same horizontal axle; they carry between the interior surfaces of their rims ten blocks at equal distances from one another on the circumference; and at first the blocks are disposed so that the mortises in each are perpendicular to a plane passing through the common axis of the two wheels, the axes of the blocks remaining always parallel to that axis. The wheels are made to revolve by a strap passing over a cylinder on the axle; the cylinder being in connection with the steam-engine: the cutting tool is applied, on a level with the axis of the wheels, to a horizontal frame which has the form of a circular arc, the centre being in the middle of that axle; and while the edge of the tool is pressed against the block it is slowly

moved along the arc. Thus, the tool acting against the block during the revolution of the latter with the wheel, and being itself in motion horizontally, the face of the block is brought to the form of a segment of a sphere. Each block is then turned on its particular axis: first one quarter round, then another quarter, and finally a third quarter round: and in each of these positions an edge or side of the block is, by the tool, brought to a form similar to that which was given to the first face; the last of the four sides being completed after each block has been turned three quarters round on its own axis. The ten blocks are then removed and ten others put in their places, to be shaped in like manner.

The blocks are not turned on their several axes by hand, the machine containing an ingenious contrivance by which such revolutions are effected. In the following cut, *AB* is the axle of the double wheel, of which *AC*, *BD* represent two of the radii, and *E* one of the blocks at the circumference. A bevelled wheel *FG* is fitted on the axle of the double wheel, and, in the teeth of this, work as many pinions, *H*, *K*, &c., as there are blocks; each pinion has an axle *LM* in the direction of a radius of the great wheel, and extending as far as the circumference of the latter; near the extremity *M* is cut what is called a perpetual screw, whose threads work in the grooves of a pulley-shaped wheel *N*, on the axle of which is the block *E*.

During the process of shaping the blocks, the wheel *FG* revolves with the great wheel, carrying with it the pinions *H*, *K*, &c., and their axles *LM*, &c., the pinions not changing their places on the circumference of *FG*, and consequently the blocks having no movements on their particular axes. But when the first faces of the ten blocks have been shaped, the whole machine is detached from the engine, and the wheel *FG*, which is capable of turning freely on the axle of the great wheel, being held fast, the latter is turned round by hand; this causes the pinions *H*, *K*, &c. to move on the circumference of *FG*, and, at the same time to revolve on their own axes; thus the axles *LM*, &c. revolve, and, on account of their connection at *N*, &c., with the axles of the blocks, the latter revolve also on their axes. The numbers of the teeth are so proportioned that four revolutions of the great wheel, while *FG* is held fast, will cause each block to turn a quarter round on its own axle: this brings a new side of each block to the circumference of the wheel, and the whole machine being then re-connected with the steam-engine, the process with the tool is again carried on till the new side of the block is shaped; the machine is then released from the engine, the blocks turned as before another quarter round, and so on.

The part *ab* represents the shaping tool, which slides between the two plates *c* and *d* of a frame which is made to slide upon the circular arc *PQ* towards either of its extremities by moving the handle *R*; and while the tool is thus made to move slowly on the arc, it is kept close to the block by pressing on the handle *s*, which turns on a pivot at *e*, against a pin at *b*.

Lastly, the blocks are taken to what is called the scoring-machine, by which there are cut on each of the faces the two grooves intended to receive the rope by which the block is to be suspended when in use: this operation is performed by means of two cutting tools, with curved edges, fitted at the opposite extremities of a small brass wheel which revolves on an axle by the connection of the latter with the steam-engine: the block is fixed in a frame in an inclined position, so that the cutting tools form a groove which commences near the pin-hole of the block and deepens gradually towards either extremity.

The sheaves are made of lignum vitæ, and plates of the required thickness being cut from the tree, each of them has a circular form given to it by means of a trepanning, or crown saw, a cylinder of steel having teeth on one of its edges, and having on its axle a tool for boring the centre hole through which the pin is to pass; the plate of wood being fixed in its place, the workman by a lever presses the saw and centre-bit against it; and these by revolving rapidly, both give a circular form to the plate and bore the hole in its centre.

The sheave is then to be prepared to receive in its centre the metal *coak* or ring through which the pin is to pass; for this purpose it is laid horizontally on a plate, which may be kept at rest, or turned round on its axis, as may be required; a drill, or cutting tool, in a vertical position, is made to form in succession three semicircular excavations of small depth at equal distances from one another about the centre hole. During the cutting of each of these the plate carrying the sheave is fixed, but in each interval it is turned one-third part round, by which means the tool is enabled to enlarge the centre hole to a small depth, quite round the latter; thus the side of the sheave is countersunk about its centre in the form of a circle having three segments cut in its circumference: the like countersinking then takes place on the other side of the sheave. The *coak*, which is made of

gun-metal and of a form to fit the countersink, is in two parts, one of them having a barrel which is to enter the centre hole; the parts are then introduced and riveted to the sheave. The middle part of the coak is then broached out so as to form a hole perfectly cylindrical; and, lastly, by a lathe also connected with the engine, the rope is formed round the circumference of the sheave.

The pins, which are of iron, are turned by a lathe of great strength, and are highly polished by being drawn with a revolving motion between two plates.

Some details have been necessarily omitted in the foregoing description, but enough are given to make the operation of these engines sufficiently clear to the general reader.

BLOCKADE, LAW OF. Whenever a war takes place it affects in various ways all states which have any connection with the belligerent powers. A principal part, accordingly, of the science of international law is that which respects the rights of such neutral states. For obvious reasons this is also the most intricate part of the subject. There is here a general rule, namely, that the neutral ought not to be at all interfered with, conflicting with a great variety of exceptions, derived from what is conceived to be the right of each of the belligerents to prosecute the object of annoying its enemy, even though (within certain limits) it inflicts injury upon a third party. In the first place, there is to be settled the question of what these limits are. It evidently would not do to say that the belligerent shall not be justified in doing anything which may in any way inconvenience a neutral power; for such a principle would go high to tie up the hands of the belligerent altogether, inasmuch as almost any hostile act whatever might in this way be construed into an injury by neutral states. They might complain, for instance, that they suffered an inconvenience when a belligerent power seized upon the ships of its enemy that were on their way to supply other countries with the ordinary articles of commerce. On the other hand, there is a manifest expediency in restricting the exercise of the rights of war, for the sake of the protection of neutrals, to as great an extent as is compatible with the effectual pursuit of the end for which war is waged. Accordingly, it has been commonly laid down, that belligerents are not to do anything which shall have a greater tendency to incommode neutrals than to benefit themselves. It is evident however that this is a very vague rule, the application of which must give rise to many questions.

It is by this rule that publicists have endeavoured to determine the extent to which the right of blockade may properly be carried, and the manner in which it ought to be exercised. We can only notice the principal conclusions to which they have come, which, indeed, so far as they are generally admitted, are nothing more than a set of rules fashioned on positive international morality (that is, so much of positive morality as states in general agree in recognising) by judicial decision. Accordingly perhaps the most complete exposition of the modern doctrine of blockade may be collected from the admirable judgments delivered in the course of the war which closed in 1815 by Sir W. Scott, afterwards Lord Stowell, while presiding over the High Court of Admiralty,¹ as reported by Dr. Edwards and Sir Chr. Robinson. The extraordinary events of that time, and the extravagant decrees of the Emperor Napoleon, celebrated as the Berlin and Milan Decrees, and the ill-advised course of retaliation adopted by our government in the Orders in Council, to which specific reference will be made immediately, raised this point of international law into unusual, but in the circumstances not undeserved, importance. It engaged the attention of the British Parliament, and filled the political literature of the day. The various pamphlets and published speeches of Lord Erskine, Mr. Stephen, Mr. (now Lord) Brougham, Mr. Alexander Baring (afterwards Lord Ashburton), Lord Sheffield, and others, which appeared in the course of the controversy respecting the Orders in Council, may also be consulted with advantage. To these may be added various articles in volumes xi., xii., xiv., and xix. of the 'Edinburgh Review,' particularly one in volume xix., pp. 290-317, headed 'Disputes with America,' written immediately before the breaking out of the war with that country.

The first and the essential circumstance necessary to make a good blockade is, that there be actually stationed at the place a sufficient force to prevent the entry or exit of vessels. Sir William Scott has said (case of the *Vrow Judith*, Jan. 17, 1799), "a blockade is a sort of circumvallation round a place by which all foreign connection and correspondence is, as far as human power can effect it, to be entirely cut off." This is in perfect accordance with the language of the convention signed between Great Britain and Russia in 1801; it states, "that in order to determine what characterises a blockaded port, that denomination is given only where there is, by the disposition of the power which attacks it with ships, stationary or sufficiently near, an evident danger in entering." Such a restriction as this, it is evident, is absolutely necessary to prevent the greatest abuse of the right of blockade. The benefit accruing to a belligerent from blockading its enemy's ports, by which it claims the privilege of seizing any vessel that attempts to touch or has actually touched at such ports, and the inconveniences thereby inflicted upon neutrals, would both, without such a provision, be absolutely unlimited. In point of fact, belligerents have frequently affected, in their declarations of blockade, to overstep the boundaries thus set to the exercise of the right. France, as Lord Brougham showed in his speech delivered before the House of Com-

mons, 1st April, 1808, in support of the petitions of London, Liverpool, and other towns against the Orders in Council, has repeatedly done so both since and previous to the Revolution. She did so in 1739, and in 1756, and also in 1796, in 1797, and in 1800. But in none of these instances were her pretended blockades either submitted to by neutrals or even, to any considerable extent, attempted to be enforced by herself. There can be no doubt that no prize court would now condemn a vessel captured for the alleged violation of any such mere nominal blockade. Accordingly, the language of the British government on this point during the last war with Russia was definite and firm beyond a doubt. In the royal declaration of the 28th of March, 1854, by which the British crown waived the right of seizing enemy's goods on board a neutral ship, these words were added: "We must support the right of a belligerent to prevent neutrals from breaking any effective blockade which may be established with an adequate force against the enemy's forts, harbours, or coasts." And finally, on the 16th of April, 1856, the Powers who were parties to the treaty of Paris of the same year, while yet assembled at Paris, agreed and solemnly declared that blockades, in order to be binding, must be effective; that is to say, maintained by a force sufficient really to prevent access to the coast of the enemy. And it was further agreed to invite the accession of the other States of the world to this and the other principles of maritime law adopted by these Powers at the same time. It has however been decided that the blockade is good although the ships stationed at the place may have been for a short time removed to a little distance by a sudden change of wind, or any similar cause; and no doubt the doctrine would still be maintained in this country, and it is likely too in the United States. But French publicists, now taking to the other extreme from that formerly pursued by their government, contend that this doctrine has the effect of giving to the mere notification the independent force of an effective blockade.

The second and only other circumstance necessary to constitute a blockade such as the prize-courts will recognise is, that the party violating it shall be proved to have been aware of its existence. There are two species of blockade: the one by the simple fact only of the place being surrounded by an effective hostile force; the other by a notification accompanied with the fact. These are attended with a corresponding difference of consequences. The effect of a notification to any foreign government would clearly be to include all the individuals of that nation; and ignorance of the blockade, though it might be a ground of appeal to the offender's own government for indemnity, could be no defence in the courts of the belligerent nation. After this, the mere act of sailing for the blockaded place is sufficient to constitute the offence of breach of blockade, and this although the intention to enter was contingent on the actual raising of the blockade. There is this further difference between these species of blockade: that in the case of a blockade *de facto*, when the fact ceases otherwise than by accident or shifting of the wind, there is immediately an end of the blockade; but where the fact is accompanied by a public notification from the government of a belligerent country to a neutral government, *prima facie* the blockade must be presumed to exist till it has been publicly repealed. At the same time, it is always in the power of governments by treaty to modify the strict rights of war for a time, and to provide that vessels belonging to subjects of the treating powers and approaching the blockaded port shall be warned off and be suffered to retire with their cargoes, unless they have already had a previous warning and neglected it. Such a treaty was concluded between Great Britain and the United States in 1794.

With regard to neutral vessels lying at the place where the blockade commences, the rule is, that they may retire freely after the notification of the blockade, taking with them the cargoes with which they may be already laden; but they must not take in any new cargo.

The offence of violation is effected either by going into the place blockaded, or by coming out of it with a cargo taken in after the commencement of the blockade. Vessels must not even approach the place with the evident intention of entering if they can effect their object. It even appears that a vessel will render itself liable to seizure and condemnation if it can be proved to have set sail with that intention. In such cases, however, it must be always difficult for the captors to make out a satisfactory case.

After a ship has once violated a blockade, it is considered that the offence is not purged, in ordinary circumstances, until she shall have returned to the port from which she originally set out; that is to say, she may be seized at any moment up to the termination of her homeward voyage; and if she is chased, after such breach of blockade, by a belligerent vessel into her own or any other port, she continues liable to seizure on coming out again from that port. If the blockade, however, has been raised before the capture, the offence is held to be no longer punishable, and a judgment of restitution will be pronounced.

The effect of a violation of blockade to the offending party when captured, is the condemnation usually of both the ship and the cargo. If, however, it can be shown that the parties to whom the cargo belongs were not implicated in the offence committed by the master of the ship, the cargo will be restored. It has sometimes on the contrary, happened that the owners of the cargo have been found to be the only guilty parties, in which case the judgment has been for the condemnation of the cargo, and the restitution of the ship.

If a place, as generally happens in the case of maritime blockades, be

blockaded by sea only, a neutral may carry on commerce with it by inland communications. The neutral vessel may enter a neighbouring port not included in the blockade with goods destined to be carried thence over land into the blockaded place.

When a place has once been notified to be blockaded, a counter notice should always be given by the blockading power when the blockade has ceased. The observance of this formality is obviously conducive to the general convenience, but there are of course no means of punishing a belligerent for its neglect.

In this country a blockade is ordered and declared by the sovereign in council. It is held, however, that a commander of a queen's ship on a station so distant as to preclude the government at home from interfering with the expedition necessary to meet the change of circumstances, may have authority delegated to him to extend or vary the blockade on the line of coast on which he is stationed. But the courts will not recognise a blockade altered in this manner within the limits of Europe. It appears to be necessary for the sake of the public convenience that the power of declaring a blockade should, as far as possible, be exercised only by the sovereign power in a state; but it would perhaps be going too far to insist that it should in no circumstances be delegated to a subordinate authority. This would seem to be something very like interfering with the internal arrangements of states.

Some very important questions connected with the law of blockade were brought into discussion in the course of the French war by the Berlin decree of Bonaparte and the orders in council of the king of Great Britain.

The Berlin decree, which was issued on the 21st of Nov., 1806, declared the whole of the British islands in a state of blockade, and all vessels, of whatever country, trading to them, liable to be captured by the ships of France. It also shut out all British vessels and produce both from France and from all the other countries then subject to the authority of the French emperor. By a subsequent decree, issued soon after in aid of this, all neutral vessels were required to carry what were called letters or certificates of origin, that is, attestations from the French consuls of the ports from which they had set out, that no part of their cargo was British. This was the revival of an expedient which had been first resorted to by the Directory in 1796.

There can be no question as to the invalidity of this blockade, according to the recognised principles of the law of nations: the essential circumstance of a good blockade, namely, the presence of a force sufficient to maintain it, was here entirely wanting.

The first step in resistance to the Berlin decree was taken by Great Britain on the 7th of January, 1807, while the Whig ministry of which Mr. Fox had been the head was still in office, by an order in council subjecting to seizure all neutral vessels trading from one hostile port in Europe to another with property belonging to an enemy. This order however is said to have been extensively evaded; while, at the same time, new efforts began to be made by the French emperor to enforce the Berlin decree. It is admitted that in the course of the months of September and October, 1807, several neutral vessels were captured for violation of that decree; that a considerable alarm was excited among the mercantile classes in this country by these acts of violence; that the premium of insurance rose; and that some suspension of trade took place. (See 'Edin. Rev.' vol. xiv. p. 442, &c.) It was contended by the supporters of the British orders in council, that the effect of the Berlin decree upon the commerce of this country during the months of August, September, and October in particular, was most severely felt. (See Mr. Stephen's 'Speech'.)

In these circumstances the British government, at the head of which Mr. Perceval now was, issued further orders in council, dated the 11th and 21st of November, 1807. These new orders declared France and all its tributary states to be in a state of blockade, and all vessels subject to seizure which were either found to have certificates of origin on board, or which should attempt to trade with any of the parts of the world thus blockaded. All neutral vessels, intended for France or any other hostile country, were ordered in all cases to touch first at some British port, and to pay custom dues there, after which they were, in certain cases, to be allowed to depart to their destination. In all cases, in like manner, vessels clearing out from a hostile port were, before proceeding farther on their voyage, to touch at a British port.

The predicament in which neutral countries were placed by this war of edicts was sufficiently embarrassing. The effect of the British orders in council is thus distinctly stated by a writer in the 'Edinburgh Review,' vol. xii. p. 229: "Taken in combination with the Berlin decree, they interdict the whole foreign trade of all neutral nations; they prohibit everything which that decree had allowed; and they enjoin those very things which are there made a ground of confiscation."

By a subsequent decree, issued by Bonaparte from Milan on the 27th of December, 1807, the British dominions in all quarters of the world were declared to be in a state of blockade, and all countries were prohibited from trading with each other in any articles produced or manufactured in the parts of the earth thus put under a ban. Various additional orders in council were also promulgated from time to time, in explanation or slight modification of those last mentioned.

It is asserted by the opponents of this policy of the British government, that the result was a diminution in the course of the following

year of the foreign trade of this country to the extent of fourteen millions sterling. It is even contended that, but for some counter-acting causes which happened to operate at the same time, the falling off would have been nearly twice as great. (See 'Edin. Rev.' vol. xiv. p. 442, &c.)

The principal branch of trade affected was that with America, which was at this time the only great neutral power in existence; and which in that capacity had, previous to the Berlin decree, been an annual purchaser of British manufactures to a large amount, partly for home consumption, but to a much larger extent for the supply of the continent. Both the Americans, therefore, and the various parties in this country interested in this export trade, exclaimed loudly against the edicts of the two belligerent powers. It appears that the American government, on application to that of France, obtained an assurance, which was deemed satisfactory, though not in an official form, that the Berlin decree would not be put in force against American vessels; but when this was urged as a sufficient reason for the revocation of the English orders in council, the English government refused to pay any attention to it, maintaining that America should insist upon a public renunciation of the obnoxious French decree.

The subject was brought before parliament in March, 1808, by motions made in both houses asserting the illegality of the orders in council. On the 1st of April the merchants of London, Liverpool, and other towns, who had petitioned for the repeal of the orders, on the ground of their injurious operation upon the commercial interests of the country, were heard at the bar by their counsel, Mr. Brougham, whose speech, as has been already mentioned, was afterwards published. The result was, that ministers consented to the institution of an inquiry into the effect of the orders, in the course of which many witnesses were brought forward both by the petitioners and by the ministers in support of their respective views. But no immediate result followed, either from this inquiry, or from a motion made in the House of Commons on the 6th of March, 1809, by Mr. Whitbread, declaratory of the expediency of acquiescing in the propositions made by the government of the United States.

On the 26th of April however a new order in council was issued, which, it was contended by the opponents of the policy hitherto pursued, did in fact amount to an abandonment of the whole principle of that policy. On the pretext that the state of circumstances, so far as the Continent was concerned, had undergone a complete change by the insurrection of the Spaniards, the blockade, which had formerly extended to all the countries under the authority of France, was now confined to France itself, to Holland, to part of Germany, and to the north of Italy; and the order which condemned vessels for having certificates of origin on board was rescinded. On the other hand, the interdict against trading with the blockaded ports was apparently made more strict and severe by the revocation of the liberty formerly given, in certain cases, to neutral vessels to sail for an enemy's port after having first touched at one in Great Britain. Upon this point however some important modifications were made by subsequent orders. A system was introduced of licensing certain vessels to proceed to hostile ports after having first touched and paid custom-dues at a British port; and this was eventually carried so far, that at last the number of such licences granted is said to have exceeded 16,000.

The position however in which America was still placed was such as almost to force her to go to war either with England or France. In this state of things, in the spring of 1812 a vigorous effort was again made by the opposition in parliament to obtain the entire removal of the orders in council. In the Lords, a motion was made by the Marquis of Lansdowne on the 28th of February, for a select committee of inquiry into the effect of the orders, but was negatived by a majority of 135 to 71. On the 3rd of March a similar motion made in the Commons by Mr. Brougham was also rejected by a majority of 216 to 144. On the 3rd of April however an order of the prince regent in council appeared in the 'Gazette,' revoking entirely the former orders in so far as regarded America, but only on the condition that the government of the United States should also revoke an order by which it had some time previously excluded British armed vessels from its ports, while it admitted those of France. This conditional revocation being still considered unsatisfactory, Lord Stanley, on the 28th of April, moved in the Commons for a committee of inquiry into the subject generally, and the discussion ended by ministers giving their assent to the motion. Many witnesses were in consequence examined, both by this committee and by another of the Lords, which sat at the same time, having been obtained on the 5th of May on the motion of Earl Fitzwilliam. When the examinations had been brought to a close, Mr. Brougham, on the 16th of June, moved in the Commons, that the crown should be addressed to recall or suspend the orders unconditionally. At the termination of this discussion ministers intimated that they were prepared to concede the question; and accordingly, on the 23rd of the same month, an unconditional suspension of the orders, in so far as America was concerned, appeared in the 'Gazette.' By this time however the government of the United States had declared war, on the ground, as is well known, not only of the orders in council, but of other alleged acts of injustice on the part of the British government.

The policy of the British government in issuing the orders in council of November, 1807, was maintained by its opponents to be wrong, on

the double ground that it was both inexpedient and not warranted by the principles of the law of nations. On the latter ground they will no doubt be found in company with all jurists of any name; the text writers on the law of nations at this day are unanimous in their favour. But upon the former, the inexpediency of such a course as was pursued by our government on that occasion, there is not now a dissentient opinion throughout the United Kingdom. It is universally condemned as impolitic and short-sighted.

BLOCKADE. This consists in surrounding a fortified place by a cordon of troops, in order to prevent supplies of provisions or warlike stores from entering, and to compel the garrison to surrender from famine or the failure of their ammunition. The generality of the ancient sieges were blockades, and two of the most memorable in Grecian history were those of Plataea and Pydna. The former lasted two years, and is remarkable for being the first of which any connected details have been given. Pydna, in which city Olympias had taken refuge, was closely invested by Cassander both by sea and land, and did not surrender till the garrison had suffered the utmost extremity of famine.

When fortresses are situated on rocky eminences, whose sides are nearly inaccessible by nature, or have been made so by human labour; when they are approachable only by narrow passes, and the surrounding country is unfavourable for the execution of the works required in carrying on a regular siege; or when the besieging army is inadequately supplied with siege matériel, their reduction is most conveniently effected by a blockade, because they can be masked by a corps of troops not so numerous as to diminish materially the strength of the army in the field; and their garrisons, being necessarily small, are unable to attempt any serious enterprise.

In Europe, however, nearly all the old fortresses of this kind have been suffered to go to ruin, the smallness of their garrisons rendering them wholly useless; and therefore, since the end of the 17th century, blockades have been much less frequent than they were before that time. During the continuance of the war which was carried on by the Germans and Venetians against the Turks, and which ended with the peace of Carlowitz in 1698, several places were taken from the Turks after having been long invested; it was thus that, in Hungary, the fort of Agria and the towns of Mongatz and Great Waradin were taken by the Imperialists, and that in the Morea, the Venetian general obtained possession of Napoli di Malvasia.

Fortified towns may be blockaded when means are wanting to execute trenches and ricochet batteries; and when besides the place is known to be incompletely furnished with the necessary stores, and to contain a numerous or disaffected population within its walls. In such circumstances it may reasonably be expected that the place will in time be surrendered, particularly if it be the seat of an extensive commerce, or if the inhabitants should be disaffected to their government. The loss occasioned by the stoppage of the usual channels of trade; the discomfort arising from being confined within the fortifications; and, chiefly, the distress brought on by the scarcity and high price of the necessaries of life, never fail to produce dissatisfaction and even tumult among the citizens; and in the end the commander of the place is generally compelled by clamour, or induced by solicitation, to comply with the wishes of the people, and to deliver up his charge to the enemy.

In the establishment of a blockade, the outposts of the garrison are first driven as near as possible to the place, and the inhabitants prevented leaving; bodies of troops are disposed in convenient situations before all the accessible fronts; these are also strengthened at intervals by redoubts containing artillery, and if the place is on the sea-coast, a naval armament watches it on that side. Corps of cavalry and infantry occupy any villages on the several roads by which it may be attempted to throw supplies into the place; small advanced posts also watch the town closely, and maintain the communications between the different divisions of the blockading corps, by which means any movement of the garrison may be immediately discovered.

The blockading corps should also be supported by a reserve, established at a greater distance from the place, to seize any convoy approaching with succours for the garrison, or repulse any relieving force which may attempt to throw supplies into the place, or send assistance to any portion of the blockading army which, being attacked by a sortie in force, may require aid.

On the other hand, in order to counteract as much as possible the efforts of the enemy, all persons who cannot be rendered serviceable in the defence, or who cannot lay in a sufficient supply of provisions for their support during the probable continuance of the blockade, are sent out of the town; the necessary quantities of provisions and military stores are provided, and secured in casemates or shell-proof blindages, if a bombardment is apprehended, and the consumption of every article is carefully economised. The garrison should keep the field as long as possible, disputing with the enemy every spot which he may endeavour to occupy, driving in all cattle, and laying waste the country, and destroying everything which may afford him cover: sorties should be made whenever a hope of success presents itself without

risking the loss of many men; and every other means should be taken as long as possible to prevent the enemy from establishing his posts, or forming redoubts about the place.

In 1757 the King of Prussia blockaded Prague, a populous city, and garrisoned by 60,000 soldiers; the investment continued six weeks, during which time all the avenues were occupied, and several engagements took place. The history of the late Peninsular war affords, however, one of the best examples of reducing a fortified town by a blockade, in that which the Duke, then the Marquis, of Wellington, caused to be established about Pampeluna in 1813. This town had a garrison consisting of more than 4000 men, while the British army could spare neither troops nor artillery sufficient to ensure its surrender by a siege. Nine strong redoubts, each capable of containing a garrison of 200 or 300 men, with some field-pieces, were constructed on commanding heights, at from 1200 to 1500 yards from the place, and served to repel every sortie from thence, while the rest of the blockading force was quartered in the neighbouring villages, or bivouacked beyond the range of the artillery of the fortress. Buildings near the latter were barricaded, and formed strong advanced posts; the roads were blocked up as usual, and small field-works covered the guards of the army. The blockade continued three months; and when Marshal Soult advanced to the relief of the town, notwithstanding that the British troops in concentrating themselves to oppose him were necessarily drawn away from the posts which they occupied, yet the precautions used were such, that no communication could take place between the garrison and the French army, though the latter was almost within sight of the ramparts.

(See Lallemand, *Traité des Opérations Secondaires de la Guerre*; Jomini, *Traité des grandes Opérations Militaires*; Colonel Sir J. T. Jones, *Journals of Sieges in Spain*.)

BLOCKHOUSE (also written **BLOCKHAUS**), among military edifices is, as the name implies, a building constructed chiefly of timber; if alone, it constitutes an independent fort; if formed in the interior of a field-work, it becomes a retrenchment or reduit, and serves to protect the defenders from the inclemency of the weather when the work is occupied during a considerable time, or to prolong the defence when the work is attacked; and, after it is taken, serves as an interior retrenchment which may prevent the enemy holding the works or enable the garrison to obtain a capitulation. Blockhouses have been principally employed in America, where from the abundance of wood they could easily be constructed. They are either one or two storied, but generally the former.

When the blockhouse is to be employed only as a retrenchment, its plan is generally a simple rectangle, and its walls consist of a single row of piles or timbers, placed upright in the ground, or, as generally made in America, of strong upright timbers at the angles, with walls of horizontal timbers, halved and notched into one another at the angles, where they overlap about six inches; these are pierced with loop-holes, at the distance of three feet from each other, in order that the building may be defended by a fire of musketry from within. The roof is formed by laying timbers horizontally across the inclosed area, and covering them with fascines and earth, or earth only. The covering materials, when the work is intended to be bomb-proof, must be at least four feet thick, since the shells fired from field-howitzers penetrate into earth nearly to that depth. The entrances, when formed in the walls, are protected by inclined blindages, or by palisades, planted close together in their front, and pierced with loop-holes; but occasionally the entrances are in the roof, and access to them is then obtained by means of ladders.

The interior breadth of the building should be about eighteen feet, in order to allow a passage between the two rows of bedsteads: these are placed with their heads to the side walls, and serve as banquettes on which the men may stand to fire through the loop-holes when the latter are much elevated above the floor, which they should be to prevent the enemy firing in through them.

Two-storied blockhouses are constructed usually by making an ordinary rectangular blockhouse with walls sufficiently strong to support an upper story of the same construction, which is put on askew, or with its sides parallel to the diagonals of the lower one. By this means a fire is obtained in front of the salients or along the capitals of the lower story, and the portions of the upper story which necessarily project over the lower one, being pierced with loop-holes downwards, act as a machicolis and supply the want of a flanking fire. These, however, can only be used advantageously in situations where they will not be exposed to artillery fire.

Reduits of this kind are nearly indispensable in situations commanded by heights; when consequently the interior of the principal work is so subject to the plunging fires of the enemy, that the defenders could not otherwise find shelter, and then the side-walls should be thick enough to resist a fire of artillery. In other circumstances it would be advisable that the parapets of the principal work should conceal the reduit from the view of the enemy: for which purpose the roof of the latter should be kept as low as possible; and, in this case, in order to afford sufficient height in the interior, which should not be less than eight feet, it may be necessary to sink the floor below the natural level of the ground.

In a mountainous country the blockhouse possesses great advantages over an ordinary field-fort, inasmuch as the interior of the latter would

be incessantly ploughed up by the fire of artillery directed into it by the enemy from the surrounding heights. Here then the blockhouse may with propriety be constructed as an independent work; its plan may have re-entering angles, or be in the form of a cross, in order to allow the faces to be defended by flanking fires of musketry from within; and the walls may be thick enough to resist the shot from light or mountain artillery. For this purpose they must be made by planting parallel to each other, at the distance of three or four feet, two rows of strong piles, those in each row being close together, and the interval between the rows being filled with earth up to the height of the loop-holes, which should now be immediately under the roof of the building. The roof must be made shell-proof as before; but it has been recommended, when the work is not overlooked by the enemy, and when its breadth will permit, to have the piles forming the side-walls long enough to rise above the roof, and, either alone, or with a mass of earth behind them, to serve as a parapet.

To prevent the enemy from setting fire to the blockhouse, it should be surrounded by a ditch; part of the earth obtained from thence should be raised against the building as high as the loop-holes, in order to strengthen it exteriorly, and the rest may be thrown beyond the counterscarp to form there what is called a reverse glacis.

Any area inclosed for the purposes of defence by piles or palisades, or by logs of timber horizontally disposed, but without a roof, and defended by loop-holes and machicolations, is sometimes called a blockhouse: more generally, however, such constructions are called stockades, under which word they will be described.

BLOCKING-COURSE. [ENTABLATURE.]

BLOW-PIPE. The instrument to which this name has been applied was originally employed by jewellers and others in the soldering of metals on the small scale, whence it derives its name in the German language, "Löthrohr," from the two words "löthen," to solder, and "rohr," a tube or pipe. When used for such purposes it is constructed of a simple metallic tube seven or eight inches in length, the bore of which at the larger extremity is about one-fourth of an inch in diameter, and gradually contracts as it approaches the other, where it terminates in an almost capillary orifice; and the instrument is formed by simply bending this tube at a right angle at an inch or an inch and a half from its finer extremity. In this form it is used by the workman to direct the flame of a lamp on the portion of solder to be employed, by which he is enabled to bring it readily and without loss of time into a state of fusion; the solder is placed on a fragment of charcoal, which he holds in his left hand, and upon which the flame is made to play by blowing a gentle current of air against it by means of the pipe.

Such was its sole use until the year 1738, when, as we are informed by Bergman, Antony Swab, a Swedish bergrath, or counsellor of mines, and a man of very considerable knowledge for his time, introduced it to the notice of the scientific world, by employing it in determining the nature of the metals in the various ores and minerals which came under his notice. Swab however wrote no work on the subject, nor does it appear to have received any particular attention from any one until Cronstedt proposed his system of mineralogy, in which the arrangement is dependent on the chemical composition of the minerals. It thus became to him of vital importance for the general adoption of his system—we may almost say for its very existence—to possess some ready and simple means of determining the constituents of mineral bodies, as it was evident that those offered by the slow and laborious operations of chemical analysis could not be generally employed by mineralogists. This he found in the blow-pipe; and by the employment of fluxes in the experiments performed with this instrument, he may be considered as the founder of a new department of the chemical science. His results are to be found in his 'System of Mineralogy,' the first edition of which was published in 1758, and was translated into English by Von Engeström in 1765; also in an essay by the latter, published in London in 1770 under the title of 'An Essay towards a System of Mineralogy,' by Cronstedt, translated from the Swedish by Von Engeström, revised and corrected by Mendez da Costa, London, 1770.

The employment of the blow-pipe in detecting the constituents of minerals being thus brought into notice, excited the attention of the chemists and mineralogists to the cultivation of this branch of chemistry, and its application to chemical analysis and to the determination of the mineralogical species. In Sweden however it still appears to have been studied with the greatest success; and it is to the chemists and mineralogists of Sweden that we are indebted for the greater portion of the information which has been received on this subject, and more particularly to Bergman, Gahn, and Berzelius. Bergman, after extending its limits by a series of original researches, in which he investigated the properties of most of the then known species of minerals, and by a more general application to chemical analysis, published the results of his observations in a treatise written in the Latin language, which appeared at Vienna in 1779, under the following title: 'De Tubo Ferruminatorio, ejusdemque usu in explorandis Corporibus, presertim Mineralibus.' A translation of the above into English will be found in the second volume of Bergman's 'Chemical and Physical Essays,' by

Dr. Cullen, London, 1788. Gahn, though indefatigable in his observations and experiments with the blow-pipe, and though far exceeding any of his predecessors both in the conception and execution of his experiments, has however left no work on the subject. As an instance of his power of detecting the presence of metallic bodies, we are told by Berzelius that he has often seen him extract from the ashes of a quarter of a sheet of paper distinct portions of copper, and that too before the knowledge of the occurrence of this metal in vegetables was known, and therefore before he could have been led from this circumstance to suspect its presence in paper.

Although we cannot but feel regret at having received no work from a man so eminently qualified to instruct on this subject as Gahn, still we must consider ourselves most happy that under such circumstances the loss of the knowledge and experience of so long and laborious a life is not also to be lamented. Fortunately for science, accident, as it were, made Berzelius the medium through which this information was to be communicated to the world; and while his good fortune in thus having it in his power to add another to the many benefits he has bestowed on mankind cannot but be envied, it must be universally felt and acknowledged that if he was favoured by fortune he proved himself one of the most worthy of her favour by the manner in which he fulfilled the task assigned to him. The assiduity of Gahn in this study, together with the circumstances to which we are indebted for the preservation of his labours, cannot be better told than in the words of Berzelius himself. "Gahn," says he, "was never without his blow-pipe, not even during his shortest journeys. Every new substance, or any thing with which he was not previously acquainted, was immediately submitted to an examination before the blow-pipe; and it was indeed an interesting sight to observe with what astonishing rapidity and certainty he was thus enabled to determine the nature of a body, which from its appearance and exterior properties could not have been recognised. Through this constant habit of using the blow-pipe he was led to invent many improvements, and to make many conveniences, which he could have at hand whether at home or abroad. He examined the action of a number of reagents, for the purpose of finding new methods of recognising bodies; and this he did in such detail, and conducted his operations with such accuracy, that all his results may be relied upon with the greatest confidence. Nevertheless it never occurred to him to give a written description of his new or improved methods: he gave himself however all possible trouble to instruct all who were willing to learn, and many foreign men of science, who passed some time with him, have made known his great dexterity in this subject; but no one has communicated a perfect knowledge of his methods.

"I had the good fortune, during the last ten years of the life of this in many respects most remarkable man, to enjoy his most intimate acquaintance. He spared himself no trouble to communicate to me all the results of his experience, and I have consequently held it as a sacred duty to allow nothing of this experience and of his labours to be lost."

Such then is the origin of Berzelius's treatise, a work which must be considered as a very high authority on this subject; and as there are translations in the English, French, and German languages, we cannot too highly recommend it to the study of those desirous of obtaining a more intimate acquaintance with the uses to which the blow-pipe may be applied. The use of the blow-pipe has also been of late years much extended and simplified by Professor Plattner, whose work on this instrument is now doubtless the best extant. An English translation by Muspratt has recently placed this excellent treatise within the reach of all students.

As our limits will not allow of our entering into a very minute description of the phenomena presented by the different chemical elements and minerals when experimented on by the blow-pipe, we must confine ourselves chiefly to a general description of the nature of the experiments performed by this instrument, and the conclusions to which it leads in determining the chemical constitution of a mineral, and consequently in recognising to what species it belongs. For this purpose it may be convenient to class the experiments under four heads:—

1. The characteristic changes produced on bodies when exposed to a high temperature.
2. The deoxidising effect of the flame, and the reduction of metals from their ores.
3. The oxidising effect, or the changes produced by the oxygen of the air on the body.
4. The action produced by the application of fluxes or reagents.

The first three classes are dependent on the unaided action of the blow-pipe flame; and as the total effect is produced by properties peculiar to particular parts of the flame even in the cases where fluxes are employed, it becomes a matter of great importance to possess a good knowledge of the flame itself, a description of which will therefore be first given. If a burning lamp or candle be carefully observed, it will be found that the flame may be divided into four parts, which may readily be distinguished from each other. First, on the lower extremity of the flame, where it is in contact with the wick, will be seen a blue portion, which extends from the wick and terminates at the points *c*, fig. 1, where the boundaries of the flame assume a vertical direction. The second most striking part of the flame is the bright

intensely luminous portion *b*, which rising as it were from out of the cup produced by the blue, ascends in the form of a cone. In close connection with this cone will be observed a smaller one (*a*) contained within it, of a dark colour, and rising from the upper extremity of the

Fig. 1.

Fig. 2.

wick; and by a very careful examination it will be found that the outer surface of the luminous cone is bounded by a thin coating of a slightly luminous flame (*c b*), which forms the continuation of the blue ring, and increases a little in thickness as it approaches the upper extremity.

The three cones thus enveloping each other differ not only in their appearance, but also in their temperature and chemical condition. Flame, as was shown by Sir Humphry Davy in the course of his beautiful and philosophical inquiries into its nature, which terminated with the discovery of his safety-lamp, is gaseous matter heated to whiteness: its most striking properties are evidently its power of communicating light and heat, and however closely these may appear to be connected, the circumstances by which the one may be developed to its greatest extent in a flame are unfavourable to the production of the other. The explanation of this is simple and obvious: the heat depends on the rapidity and energy of the chemical combinations taking place; the light, on the contrary, on the quantity of the matter kept at the white heat, and on the length of time it remains in that state. If therefore into a stream of burning gas (to take a particular case, let it be coal gas) a jet of oxygen be conducted, the combustion will be immediately rendered more rapid, the temperature of the flame will consequently rise, while its illuminating power diminishes, as will probably have been observed by many who have seen the oxyhydrogen flames, where the light is derived only from the strongly heated chalk, not from the burning gases. On applying these views to the common flame, the existence of the three concentric cones will be readily understood: in the exterior cone, the inflammable gases arising from the decomposition of the burning material come in direct contact with the atmosphere, are well supplied with oxygen, and they consequently here undergo a more rapid combustion than the interior enclosed portions: here therefore will be found the hottest points of the flame. That such is really the fact may be proved experimentally, by holding a fine iron or platinum wire across the flame, when it will be found to glow most strongly in the points of its emergence from the luminous cone, and by holding the wire at different elevations in the flame, it will be found that the portion of the outer cone immediately above *c*, the upper ridge of the blue cup, is the point of greatest heat. In the most luminous cone the combustion is slower, and in the interior darker portion the gases have not yet come into contact with the air, and are still unchanged.

If a fine current of air be now directed into the flame by means of the blow-pipe, it will assume the appearance seen in *fig. 2*: in the centre of the flame, and immediately proceeding from the orifice of the tube, a long and thin blue portion in the position *d e* of the figure will be seen; this corresponds with the blue cup of the natural flame. But it was in the upper edge of this cup, in which were found the points of greatest heat, and the same is true here also, with this difference however, that while in the natural flame these points were spread over a considerable circle, *c c*, in the blow-pipe flame they are all collected into the one point *e*, where their united effect is of course proportionably great. The reason therefore of the high temperature which may be produced by the blow-pipe is the result of the concentration of the hottest points of the flame into a focus; and another circumstance tends also to heighten this effect, that while in the natural flame the points of greatest heat are on its outer boundaries, and are therefore rapidly robbed of their temperature, they here occur encased by the luminous flame which thus protects them against the loss of temperature from this cause.

The blow-pipe employed by the workman in the soldering of metals, and constructed as was first described, cannot be employed in these operations, owing to the collection of the water from the condensed moisture of the breath on continuing the blast any time. This incon-

venience is avoided by making the blow-pipe of two pieces, and by interposing between these a receptacle for retaining the water, which is thus prevented from entering into the finer part of the pipe where it would obstruct the current of air. In using the blow-pipe the operator must not employ his lungs in producing the current of air, as it would not only be detrimental to his health, but he would be unable to sustain the blast a sufficient length of time to ensure the necessary effects: it is produced by inflating the mouth with air, which is then forced through the tube by contracting the muscles of the cheeks, and by a little practice the blast may be thus sustained for a considerable time, the process of respiration being unaffected, the only inconvenience arising from the fatigue of the muscles of the cheeks from their unusual exercise. The power of being able to perform this depends on the individual being able to keep his mouth inflated while he respires. After this has been learnt, some little experience will be required to enable the operator to regulate the strength of the blast, so as to produce the most powerful heat, as it must be neither too strong nor too weak; in the first case the heat is diminished in its action by an excess of air, and in the second too feeble a flame is produced.

We now proceed to the experiments themselves to which the blow-pipe may be applied, and we commence with those which fall under the first class: The changes produced on a body when exposed to a high temperature. Of these, four are particularly worthy of notice:—

Its fusibility.

The changes produced in its colour.

The volatilisation of the substance under examination.

The volatilisation of one or more of its component parts.

When the various elements or their compounds, which occur in a solid form at the usual temperature, for these alone can here be considered, are exposed to heat, there is always evidence of a force tending to overcome that cohesion of their particles to which they owe their solid form, and it is believed that by a sufficient degree of temperature any body whatever might be made to pass to the state of vapour, either immediately or through the intermediate stage of fluidity. However this may be, it is well known that the temperature at which such changes are effected, varies with each element, and the point which the blow-pipe first informs us upon is, whether the body is one of those which are unchanged or not at the degree of heat capable of being produced by means of it; and according to the result we know among what class of bodies the one under consideration will be found. Nor is this mere fact the sole guide to the knowledge of the body under examination; the facility or difficulty with which the change is effected, the characters of the substance in its changed form, the appearance it assumes on being again allowed to cool, open to us new sources of information, and each must be carefully observed. Thus, in some minerals the fusion is produced with ease; in others again, it can only be effected slowly, and by the strongest heat we can produce; while in a third case, our efforts will only be sufficient to round off the sharp edge of a fine fragment.

But these are by no means the most important changes, the relations of the elements to oxygen gas being decidedly more interesting and instructive. When any substance combines with oxygen gas it is said to be oxidised, and when a compound of oxygen with any base loses oxygen, it is said to be deoxidised, or reduced to a lower state of oxidation, according as it has lost the whole or a part of its oxygen. Most bodies, and particularly all the metals, are capable of undergoing the one or the other of these changes; and as by means of the blow-pipe we have it in our power to produce at pleasure the conditions under which a metal is liable to be oxidised, as well as those which are favourable to its reduction, should it be present in the form of an oxide; and as these changes are usually accompanied with striking and characteristic phenomena, the blow-pipe is thus the most powerful instrument in detecting the presence of metals, which may in many cases be extracted in their perfect metallic form from the smallest fragment of their ore.

The oxidation will be produced by holding the body before the outer extremity of the flame, where the elements being heated in contact with the oxygen of the air, are placed in the most favourable circumstances for combining with it. This takes place the more readily the further the assay is held from the flame, provided a sufficient temperature is at the same time obtained; nor is it necessary that this should be very great, since too great a heat is disadvantageous, particularly when the support is of charcoal. This process will be best performed with a pipe of comparatively large orifice, and when the material is kept at a low red heat.

The deoxidation or reduction requires a small orifice, and the substance under examination should be as much as possible surrounded by the luminous flame, by which means it is cut off from contact with the atmospheric oxygen, and is surrounded with a glowing combustible gas, by which it is deprived of its oxygen. In performing this operation, which is infinitely more difficult than that of oxidation, particular attention must be paid to keep the assay constantly in the luminous flame, as the action is but little assisted by the charcoal on which the substance rests. Berzelius recommends the beginner to practise himself in the reduction of metals by fusing small grains of tin on charcoal, and to endeavour to keep it in that state without allowing its surface to lose the metallic glance, which it does owing to the formation of the oxide, the instant it is removed from the deoxidising flame. This

operation should first be attempted on very small fragments, as the difficulty increases with the size of the tin grains.

We now come to speak of the experiments in which fluxes are employed, the most important of which and their uses will be briefly described. They are, carbonate of soda, borate of soda, the double phosphate of soda and ammonia, saltpetre, boracic acid, bisulphate of potash, gypsum, fluor-spar, nitrate of cobalt, tin, iron, lead. Of these the first three only are of general use, while the others are employed to test the presence of particular bodies; we shall confine our attention therefore to the former, as to touch upon the particular cases in which the others may be advantageous would not only lead us too much into detail, but belongs more particularly to the chemical description of the properties of these bodies.

Care should be taken that the carbonate of soda employed for these experiments be free from any impurities, particularly from the sulphate. The purest which can be purchased is the bicarbonate of commerce; if this cannot be obtained, a saturated solution of the ordinary carbonate should be taken, through which a current of carbonic acid must be transmitted, when the bicarbonate will be precipitated in the form of fine grains, which must be washed with cold water and then dried. It may be tested for sulphuric acid by means of the blow-pipe itself in the following manner: Let a glass be formed by fusing a portion of the carbonate of soda with a small quantity of pure silica, and let the resulting glass be well acted on by the deoxidising flame. If on cooling it retains its colourless condition, the soda may be considered free from sulphuric acid, the presence of which would be indicated by the glass assuming a yellow passing into a hyacinth-red colour, owing to the presence of the liver of sulphur. The application of carbonate of soda answers two purposes; to determine whether the body is fusible, in it as a flux, and to assist in the reduction of metals. The carbonate of soda is best applied by mixing it in powder with the substance to be examined, which should also be in powder; the mixture is formed into a paste by the addition of a little water, a small portion of which must then be placed on the charcoal, where, after drying, it must be brought into a state of fusion. It is usual for the carbonate of soda, as soon as it is fused, to be entirely absorbed by the charcoal, but it is not on that account less active; a continued effervescence is observed on the substance under examination, and its fusibility is indicated by the formation of a glass globule.

But the greatest use of carbonate of soda is decidedly in promoting the reduction of metals, which it does in a most unaccountable manner. If a small quantity of the oxide of tin be placed on the charcoal, a dexterous blower, at some expense of time and trouble, will be able to obtain from it a small globule of metallic tin. If, however, a little carbonate of soda be added to the oxide of tin, the reduction is effected with ease and rapidity.

The influence of the carbonate of soda in this operation is not understood, but its action is constant; and Gahn has given the following process, by which the metals platinum, gold, silver, molybdenum, tungsten, antimony, tellurium, bismuth, tin, lead, copper, nickel, cobalt, and iron may be obtained, and consequently their presence detected, whenever they occur in any ore:—

The assay is reduced to powder, and formed as before into a paste with the moistened carbonate of soda; this must then be placed on the charcoal, and submitted to the action of a good reducing flame. After some time an additional quantity of soda salt must be added, and the blast must be again renewed, and this process must be repeated until the whole of the assay is absorbed by the charcoal. When this is entirely effected, those portions of the charcoal which have thus become saturated with carbonate of soda, must be moistened by a few drops of water; and they must then be carefully removed with a knife and reduced to powder in an agate mortar. This must then be washed, by which the fine and light particles of charcoal may be readily removed from the metallic particles, which, if any be present, will be found in a pure metallic form in the mortar. The form in which the metal will be found depends on its fusibility and malleability; should it possess these properties, it will be formed into small thin leaves; if not, it will be found as a metallic powder. By this process the operator should be aware that the metals antimony, bismuth, and tellurium may have escaped his observation, from having been volatilised as soon as reduced, which is also always the case with selenium, arsenic, cadmium, zinc, and mercury, which can only be obtained by sublimation.

The borate of soda of commerce is never sufficiently pure for these purposes, but it may readily be obtained fit for use by solution in pure water and re-crystallisation. It may be employed either in the form of small grains, or of powder, or it may be first fused to free it from its water of crystallisation. The advantages of its use in the blow-pipe are dependent on its forming a most powerful flux, by which a number of otherwise refractory substances may readily be brought into a state of fusion. It is usual, in the first place, to endeavour to fuse a small fragment of the assay; as, if this process be successful, we are able to observe the phenomena taking place during the fusion better than when it is applied in the form of a powder; and what is the most important, we see whether the assay is partially or entirely fusible in this flux. The principal facts to be observed are, whether the fusion is accompanied with effervescence, or whether it takes place tranquilly; to examine the colour of the glass when obtained, and the changes it undergoes according as it is acted on by the oxidising or reducing

flame, and also to observe whether any change takes place either in the colour or transparency of the glass as it cools.

The microcosmic salt, to use the term by which it is usually designated in works on this subject, is a double salt of phosphoric acid, ammonia, and soda. It is best prepared, according to Berzelius, by adding to a solution of 16 parts of chloride of ammonium in a small quantity of boiling water 100 parts of crystallised phosphate of soda: this latter must then be brought also to a state of solution over the fire, after which the solution must be immediately filtered, and then be allowed to cool slowly, when the double salt will be deposited as crystals. It may be considered as pure if the crystals when fused give a glass which does not become opaque on cooling. The object of this salt is to enable us to try the action of a free and strong acid on the assay, which is best obtained by this means, as on heating the ammonia is driven off, and the acid with which it was combined is then at liberty to exercise its influence on the body tested. It is therefore a powerful agent in proving the presence of the metallic oxides, with which it frequently forms characteristic coloured salts; and it is also a good test for determining the presence of silica in minerals, the phosphoric acid depriving it of the bases with which it was combined, and presenting it in the form of a gelatinous substance.

In subjecting metallic oxides to qualitative examination before the blow-pipe with the above-mentioned reagents, which fuse at the temperature employed, a stout platinum wire is bent in the form of an ear, of about one-sixth of an inch in diameter, around the tapering nozzle of the blow-pipe. Such a loop is then heated red hot, and plunged into the powdered flux which is to be used. The particles of flux which thus become attached to the wire, are again heated and made to take up some more of the flux, until enough of the latter is attached to form a bead filling the entire ear. Borax, microcosmic salt, and saltpetre give in this way transparent beads; carbonate of soda, and a mixture of this with nitre give a milky enamel; in all cases the bead so formed must be colourless.

The following table taken from Plattner's elaborate treatise on the blow-pipe, gives the reactions of the principal metallic oxides when heated in the oxidising and reducing blow-pipe flames, respectively with borax and microcosmic salt:—

The alkalis, when heated by themselves in either of the blow-pipe flames, impart a colour to the flame which is probably the colour of

the vapour of the volatilised alkali. Potash colours the flame violet; lithia, red; and soda, yellow. The colouring power of soda being much greater than that of potash, a mixture of the two shows the reaction for soda. But if such a flame be looked at through a violet-coloured glass, the yellow light of the soda flame is absorbed, and the violet colour of the potassium is seen, even if only a small quantity of the latter metal be present.

Metallic tin is employed with difficultly reducible metals; its easy fusibility brings it in contact with the metallic oxides, and assists in their reduction.

Nitrate of potash is used to effect the oxidation of those metals, whose higher oxides furnish characteristic compounds with the alkalis. Thus an oxide of chromium heated with nitrate of potash before the blow-pipe, yields chromate of potash; a yellow salt in which the chromic acid can be easily detected. Manganese furnishes, when heated with nitrate of potash and carbonate of soda, a characteristically green-coloured manganate of soda.

BLOWING-MACHINES are contrivances for producing a current of air for the purpose of exciting the requisite intensity of combustion for metallurgical and other operations which require great heat. The simpler kinds are described under BELLOWS; but the larger and more complex varieties are here noticed.

It will be remembered that the familiar implement, bellows, consists of an air-tight chamber of variable dimensions, having one aperture closed by a valve which can only open inwards, and another, which is connected either directly or indirectly with the nozzle, or pipe for the exit of the current of air, closed by a valve which can only open outwards. When, by the application of mechanical force, this chamber is distended or enlarged, the pressure of the external air opens the valve which opens inwards, and consequently the chamber becomes filled with air; but when, by an altered application of power, the chamber is compressed so as to reduce its capacity, the condensation of the included air causes the valve by which it entered to close, and that which opens outwards to open, so that the air escapes by the nozzle, with a degree of force and rapidity proportionate to the pressure employed in compressing the chamber. The leathern bag of the musical instrument called a bagpipe is an example of such a variable, or expansible and compressible, chamber, and would therefore, if fitted with a nozzle, form a substitute for the common domestic bellows; but the same effect is produced, in a much more convenient way, by the use of a chamber formed of two boards, the edges of which are connected by pieces of leather laid in folds in such a manner that the upper board may be raised or depressed at pleasure, while the lower board remains stationary.

The blast produced by such a machine as has been described is intermittent, and also variable in intensity. The first of these defects may be remedied by employing two separate bellows or pairs of bellows, worked alternately, so that the one may be expelling air while the other is drawing in a fresh supply. While, however, the blast thus produced is continuous, it is by no means equable in force. To remedy this defect the air expelled from the chamber already described should be forced into a second chamber, like it, of variable dimensions, but compressed by a weight so as to produce a constant steady pressure; and the nozzle should be made to open into the second chamber. In forge-bellows of this construction there are three boards, connected by leather sides which are kept in regular folds by hoops of cane. The middle board is fixed in a horizontal position, and has the nozzle attached to it, while the upper and lower boards are moveable, and are loaded with weights; the effect of which is that when the machine is at rest the chamber formed between the upper and the middle boards is collapsed, while that between the middle and the lower boards is distended and full of air. When in use the lower board is raised by means of a lever and chain, and the air enclosed between it and the middle board is forced through a valve into the upper chamber; and by the rapid repetition of this action the upper chamber is filled with air more rapidly than the nozzle can carry it off, so that the upper board rises. The working of the bellows may then be suspended for a time; seeing that a continuous and equable blast will be maintained by the pressure of the loaded upper board until it has, by the complete expulsion of the air, descended to its original position. It should be remembered that this perfect equability of blast is only maintained while the working of the bellows is suspended, because during that time the blast is produced solely by the pressure of the loaded board; while, during the working of the bellows, the pressure alternates between that and the superior pressure produced by the influx of air from the lower chamber, thereby causing the upper board to rise and fall with each stroke. Many smiths' bellows are made of the pear-shaped form common to hand-bellows, and have the boards, or at least the lower and middle boards, united by a kind of hinge-joint; but the superior machines of this description have the boards circular, and the working apparatus so arranged as to make their action parallel; and in some cases, as for portable forges, helical springs are applied to the boards in lieu of weights.

Beckmann ('History of Inventions') observes that large bellows, such as were formerly used in smelting-houses, when made with leather, were attended with many inconveniences. They require careful management and expensive repairs, and wear out after a few years' use; the leather needs to be frequently greased or oiled, in

order, if it be thin, to prevent the enclosed air from passing through it, or, if thick, to keep the leather soft and pliable, and prevent it from cracking in the folds. These defects led to the invention, apparently in Germany, in the 16th or 17th century, of bellows formed entirely (excepting the nozzle and hinge-joint) of wood; these were long used in metallurgic operations on the Continent, and appear, from what Beckmann says as to their efficiency, to be well adapted for use where more perfect machines are unattainable. The annexed cut, representing a side elevation of such an apparatus, will sufficiently explain the structure of wooden bellows. In this figure *a* represents a wooden box of an oblong square form, the upper edge of which is indicated by dotted lines. It is open at the top, and from one end of it proceeds the nozzle *b*, which, as well as the bottom board of the box, is supplied with a flap-valve, like common bellows. This box is fixed in a horizontal position, and is covered by the box *c*, which is open at the bottom, and is so much larger than *a* as to allow its sides to slide up

and down outside the sides of the lower box without actual contact. The two boxes are united at the nozzle end by a hinge-joint formed by the bolt *d*, and the upper box is capable of being worked up and down by the projecting handle *e*. Great friction would be occasioned if an attempt were made to obtain a close fit by the accurate adjustment of the boxes one to the other; and it would be impossible, in consequence of the shrinking and warping of the wood, to make the machine air-tight; but this difficulty is obviated by attaching thin slips of wood to the inner sides of the box *c* in such a manner as to fill up the space between the two boxes: such slips being rendered very flexible by cutting them nearly through with a saw at intervals of fifteen or eighteen inches, and by being pressed into close contact with the sides of the box *a* by small metal springs. The same object might be readily effected by slips of leather. Wooden bellows of this construction are both cheap and exceedingly durable, the slips or laths which render them air-tight being the only part liable to wear; and these are easily replaced. Though we find no notice of such a modification of them, a very trifling exercise of ingenuity would be sufficient to form double bellows of this simple character. The Rev. John Williams, when serving his life of usefulness as a missionary in the South Sea Islands, taught the natives how to make a blowing-machine. This apparatus, invented by him in the absence of any available information respecting such contrivances, consisted of two square boxes containing pistons that were alternately raised by levers, and suffered to fall by their weight, aided by a load of stones; the whole forming a rude imitation—rather of the cylinder blowing-engines now used in iron-works, than of common bellows.

A very different kind of blowing-machine, which appears to be of French origin, and has been much used for blast-furnaces on the Continent, and also, we believe, in the United States of North America, though it does not appear to have been much adopted in this country, is the water blowing-engine, otherwise called *trombe* or *trompe*, in which water is allowed to fall in a minutely divided stream by passing through a colander, or by some other contrivance, down a large tube in the sides of which, near the upper end, are several apertures for the admission of air. In so falling the water draws with it a great quantity of air, which passes with it into a vessel at the bottom of the pipe, where the water dashes upon a pedestal which disperses it through the vessel. By this action the separation of the air and water appears to be facilitated; and consequently the air collects in the upper part of the vessel, whence it is conducted by a pipe to the furnace; while the water escapes by apertures provided for the purpose in the lower part of the vessel. The action of this kind of blowing-engine, which is represented in several different forms, has been variously explained by different writers; the powerful current of air produced by it has been compared to the wind which accompanies violent showers of rain. It is worthy of remark, as probably indicative of the origin of its name, if not also of the invention of this apparatus, that its French name *trombe* is the same as that of the meteorological phenomenon which we call a water-spout.

The great improvements which have been effected in the iron manufacture within the last century are, in a great measure, due to the introduction of very powerful blowing-machines, in which the air is alternately drawn into and expelled from large cylinders, resembling those of a steam-engine, by the action of pistons impelled by a connection with water-wheels or steam-engines. The first blowing-machines or force-pumps of this character on a large scale were those of the Carron foundry, constructed by Smeaton, and set to work in the year 1760. The arrangement of the piston and valves is so similar to that of a steam-engine cylinder as to need no detailed description. In

some cases, where steam is the moving power, the piston-rod of a double-acting blowing-cylinder (in which a blast is produced by every stroke, whether upwards or downwards), is connected directly with the vibrating beam of a steam-engine; in others the motion is transmitted through a series of cranks, so that two, three, or four blowing-cylinders may be worked in succession. These generally force the air into an air-chest of large dimensions, which is usually formed of iron, but sometimes of masonry, and from which it is conducted to the blast-pipes, which are called *tuyeres* or *tweers*. Barlow, in his 'Treatise on Machinery and Manufactures,' part of the 'Encyclopædia Metropolitana,' described a very powerful blowing-machine at Woolwich Dockyard, in which four cylinders supplied air, at a pressure of a quarter of a pound to the square inch, to a large air-chest from which pipes extended to all the forges and fires in the smithy, the pipes being supplied with cocks by which the blast could be turned off or on at pleasure. To ensure equability of pressure, a regulating cylinder, with a piston loaded to the required pressure, was used; and whenever the pressure exceeded the required amount, it raised the piston, and the air escaped like steam from a safety-valve. Owing to the using of sliding instead of clack or flap-valves in the blowing-cylinders, this machine worked very quietly. Another mode of regulating the blast is to throw the air from the cylinders into a large iron box inverted in a cistern of water, and somewhat resembling a gasometer, but so fixed as to be incapable of motion. The effect therefore of the condensation of air in the box is to force some of the water out; and the difference between the level of the water within and without the box forms a measure of the degree of condensation or pressure. In using such an apparatus care must be taken to conduct the air-pipes at so high a level as to render the forcing of water into the furnace impossible. The blast thus produced is exceedingly cold, which is a great disadvantage in a smelting-furnace. For a notice of the advantages of a hot blast see IRON MANUFACTURE.

The *water-bellows* is a simple kind of blowing-machine the invention of which we have seen attributed to Hornblower, one of the early English improvers of the steam-engine. It consists of two iron boxes, or hollow vessels with their under sides open, suspended from the opposite ends of a vibrating beam, resembling that of a steam-engine. The lower edges of these vessels dip into two cisterns of water, within which, rising above the surface of the water, are pipes connected with the blast or air chamber. When, by the motion of the beam, one of the vessels is forced down into the cistern, it compresses the air enclosed between it and the surface of the water, and consequently forces it along the blast-pipe. The other vessel, meanwhile, as it rises admits a fresh supply of air through a valve which opens inwards; and this air is forced into the blast-pipe in like way when the action of the beam is reversed. Another machine of similar character, but still more simple, consists of a cask or cask-like vessel suspended on an axle in a horizontal position, so as to be capable of an oscillating motion. This cask is divided longitudinally by a vertical partition, reaching from the top very nearly to the bottom, and is about half filled with water. When the cask is turned a little upon its axis, as the water retains its level, the air at one side of the partition is condensed, and escapes through a valve into a pipe which conducts to the air-chamber or reservoir; while, owing to the enlargement of the space on the opposite side of the partition, air enters it through a valve opening inwards. On reversing the inclination of the cask, the case is reversed, and the air which entered before is expelled, while a fresh supply is drawn in on the opposite side of the partition. This is the most simple form of the apparatus, but far more perfect and more complicated machines are constructed on the same principle.

Barlow, in the 'Treatise' above cited, described a simple and powerful blowing-machine used at Sharp and Roberts's engine manufactory, at Manchester, which may be compared to an Archimedean screw, excepting that, instead of raising water, its object is to impel air. It is partly immersed in a reservoir of water, and is turned by a steam-engine. Vaughan's blowing-machine is a well-contrived substitute for a cylinder and piston engine, in which the required effect is produced by the backwards and forwards motion of square pistons in two oblong boxes, placed side by side, each of which may be compared to a double-acting cylinder. This contrivance is based upon the rude bellows used by Chinese smiths. Blowing-machines in which the current is produced by means of fanners are noticed in BELLOWS; and their application to steam-carriage furnaces is alluded to in STEAM-CARRIAGE.

BLUBBER. [WHALE FISHING.]

BLUE, as a pigment. The substances used for this purpose are of very different natures, and derived from various sources: they are all compound bodies, some are natural and others artificial. They are derived almost entirely from the vegetable and mineral kingdoms, though the first which we shall describe is partly prepared from animal matter, namely:—

Prussian Blue.—This beautiful pigment was discovered by accident in 1710, by Diesbach, a manufacturer of Berlin; but the method of preparing it was first described by Woodward in the 'Philosophical Transactions' of 1724. The first step in the operation is to calcine a mixture of potash or its carbonate, with animal matter that contains nitrogen, as blood, hoofs, or horns, in an iron vessel, till it ceases to burn with flame. The residual matter is then suffered to cool, the

soluble portion of it dissolved in water, and the solution, when sufficiently concentrated, yields fine yellow crystals on cooling. This salt, commonly called ferrocyanide of potassium, or prussiate of potash, is a double cyanide of potassium and iron, consisting of

2 Equivalents cyanide of potassium	129.9
1 Equivalent cyanide of iron	54.0
3 Equivalents water	27.0
	210.9

When a solution of this salt is poured into one of protosulphate of iron, a perfectly white precipitate is formed, provided no persulphate be present; but if the latter salt be present, then the precipitate is of a bluish-gray colour; in both cases it becomes, by exposure to the air, of a fine blue, and is then washed and dried for use. The chemical change by which the white precipitate is produced may be thus expressed:

And on exposure to air, the white precipitate becomes oxidised and converted into ferrocyanide of potassium, which dissolves, and basic Prussian blue. Neglecting the ferrocyanide of potassium, this change may be thus expressed:

The action of strong acids removes the sesquioxide of iron (Fe_2O_3), leaving ordinary Prussian blue ($\text{Fe}_7\text{Cy}_9 = 2\text{Fe}_2\text{Cy}_3 + 3\text{FeCy}$).

Very commonly the solution of cyanide of potassium and iron, procured from the residue of the calcination, is not put to crystallise, but is added at once to the solution of sulphate of iron. In this case, on account of the excess of potash which it contains, a portion of iron in a state of oxide is precipitated uncombined with the colouring matter; in order to prevent this from injuring the colour of the pigment, either dilute sulphuric acid is added, which dissolves it without acting on the Prussian blue; or alum is mixed with the sulphate of iron, and the uncombined potash uniting with its sulphuric acid, alumina is precipitated instead of oxide of iron, which merely dilutes without otherwise injuring the colour of the product. When a solution of a persalt of iron, such as the nitrate, is used, the precipitate is immediately obtained of a fine blue; but this process does not answer in manufacturing.

Prussian blue is inodorous, tasteless, insoluble in water, alcohol, ether, and oils. It is hygrometric, attracting water strongly from the air, which it retains until heated to nearly 280° . Diluted acids do not act upon this substance; but strong sulphuric acid dissolves it, forming a white compound similar to that of starch and water in appearance. On the addition of water the blue colour is restored. Nitric acid and hydrochloric acid, when concentrated, both decompose it, and the same effect is produced by the alkalies and alkaline earths, but with different results. It is also decomposed by a strong heat. Prussian blue is employed both as a water colour and in oil; in the latter case, on account of the deficiency of what is termed *body*, it is usually mixed with white lead, and it will bear admixture with a large portion of this, on account of the intensity of its colour. Its stability is very considerable, and it is not only used as a pigment but also as a dye. According to Berzelius, it was used in Sweden instead of smalt, to give writing-paper a blue tint, but the paper was found to acquire a disagreeable greenish hue.

Indigo.—This fine blue is extracted from different species of *indigofera* in the East Indies and Guatemala in South America. For the methods of procuring the colour from the plant, and the various substances with which it is mixed, we refer to the article INDIGO, here merely stating the properties of the blue pigment usually met with by that name in small cubic pieces. The colour is extremely deep, the fracture is earthy, but becomes brilliant and of a copper-red colour when rubbed by a hard body, and according to the degree to which this effect is produced, the better is the indigo reckoned. Even in this state, however, it is mixed with some foreign matters, which may generally be separated by water, alcohol, solution of potash and dilute acid, in all of which pure indigo is insoluble. It may also be purified by sublimation, but the process is difficult of management, for if the heat be rather greater than necessary, the indigo is decomposed. Another method of procuring pure indigo is to take the solution of indigo prepared by dyers, and agitate it in contact with atmospheric air. This solution is prepared by mixing blue indigo in powder with lime and a solution of protosulphate of iron; the lime decomposes the sulphate of iron, precipitating its protoxide; this acting upon the indigo, in the presence of water causes it to combine with hydrogen, by which it is rendered colourless and also soluble in water; if this solution be agitated with atmospheric air, the indigo, becoming dehydrogenised and regaining its colour, is precipitated, and when washed with a little dilute hydrochloric acid and dried, it is pure. Indigo, except when used as a water-colour, requires white lead to give it body; it is a colour of considerable permanency. Strong nitric acid decomposes it, but it

differs from most vegetable products, and especially vegetable colours, in being perfectly soluble in concentrated sulphuric acid. The colour is most intense, and this solution is employed in dyeing what is called Saxon blue. Several compounds are here formed, which will be described under the head of INDIGO.

The colour of indigo is entirely destroyed by chlorine, and also by chromic acid and oxidising agents in general.

Blue Verditer.—This pigment is used as a water-colour, and chiefly in the manufacture of paper-hangings. It is a gritty powder of a very fine light blue, and consists of carbonate of copper united with water. It is prepared by precipitation from the solution of nitrate of copper which results from the refining of silver by precipitating the silver with copper. The exact mode of operating is not generally known, and success probably depends upon some minute circumstance in the manipulation.

This colour is readily acted upon by the acids even in their dilute state; they evolve its carbonic acid, and dissolve the oxide of copper; the alkalis, potash and soda, and lime-water, combine with the carbonic acid, and separate oxide of copper; it is blackened by sulphuretted hydrogen, and it is decomposed at a high temperature. It ought, therefore, not to be used by artists.

Ultra-marine.—This splendid and permanent blue pigment was originally, and indeed until within a few years exclusively, prepared from a mineral called Azure Stone, or Lapis Lazuli, the finest kinds of which are brought from China, Persia, and Great Bucharía. In the 89th vol. of the 'Annales de Chimie,' M. Tassaert has noticed the accidental formation of ultra-marine in a furnace used for the manufacture of soda; and about the year 1828, M. Gmelin of Tübingen, and M. Guimet of Lyons, both succeeded in forming this colour artificially, and it is now prepared in large quantity, of quality equal to the natural product. The former of these chemists has given the following process for making this pigment, and he asserts that it will infallibly succeed: Prepare hydrate of silica and alumina, the first by fusing powdered quartz with four times its weight of carbonate of potash, dissolving the fused mass in water and precipitating the silica by hydrochloric acid; the second by decomposing a solution of alum with ammonia. Wash these two earths carefully with boiling water; and by drying portions of the moist precipitates, ascertain the quantity of dry earths which they contain. Then dissolve as much of the hydrate of silica as a solution of soda will take up, and determine the quantity. Lastly, for 72 parts of anhydrous silica take 70 parts of dry alumina, add them to the alkaline solution of silica, and evaporate, constantly stirring till the residue is nearly dry: this is the basis of the colour.

Put into a Hessian crucible, which has a cover that fits closely, a mixture of two parts of sulphur and one part of anhydrous carbonate of soda; cover and heat the mixture moderately till it fuses; then gradually throw in small portions of the mixture above described, waiting till the effervescence is over before a fresh portion is added. Keep the mixture at a moderate red heat for an hour. If there be an excess of sulphur it is to be expelled by a moderate heat, and if all parts should not be equally coloured, the finer portion after powdering may be separated by washing with water, 'Annales de Chimie et de Physique,' 37, 409. According to the author of this process, sulphuret of sodium is the colouring principle of the lapis lazuli, and of course of the artificial as well as the natural ultramarine.

This pigment loses its colour totally by being put into an acid, and although there is no perceptible effervescence, a slight smell of sulphuretted hydrogen gas is recognised; the residue is of a dirty white colour; the alkalis do not act upon this colour, nor is it destroyed by exposure to a red heat.

It was formerly, on account of its high price, used almost exclusively by artists, both as a water-colour and in oil; but the reduced charge at which it is now made has caused it to be extensively employed by paper-stainers and calico-printers.

Thenard's Blue.—This was proposed as a substitute for ultra-marine before the invention above described had rendered this latter colour easily obtainable at a moderate price. According to Thenard ('*Traité de Chimie*, tome i.) this pigment, the base of which is either a phosphate or arseniate of cobalt, is prepared by adding a solution of phosphate of soda to one of nitrate of cobalt; the precipitated phosphate of cobalt, after due washing, is to be mixed with moist hydrate of alumina, the proportions being one of the phosphate to eight parts of the hydrate; or half the quantity of arseniate of cobalt may be substituted for the phosphate.

These substances are to be thoroughly mixed and then dried in a stove, and when the mass has become brittle it is to be calcined in a covered crucible at a cherry-red heat for half an hour.

This colour is one of great permanence, but is not so fine as the ultramarine, and is not now much used.

Small is a blue colour also prepared from cobalt, but is generally used rather to diminish the yellow tint of writing paper and of linen, and to give a bluish colour to starch, than strictly speaking as a pigment; it is merely glass rendered blue by oxide of cobalt, and this when reduced to a very fine powder is commonly called *powder-blue*.

[COBALT.]

BLUE, PRUSSIAN. [BLUE.]

BLUE VITRIOL. [COPPER, SULPHATE OF.]

BLUNDERBUSS. [ARMS.]

BOARD, a word used to denote, in their collective capacity, certain persons to whom is intrusted the management of some office or department, usually of a public or corporate character. Thus, the lords of the treasury and admiralty, the commissioners of customs, the lords of the committee of the privy council for the affairs of trade, &c., are, when met together for the transaction of the business of their respective offices, styled the Board of Treasury, the Board of Admiralty, the Board of Customs, the Board of Trade, the Poor-Law Board, &c. The same word is used to designate the persons chosen from among the proprietors to manage the operations of any joint-stock association, who are styled the Board of Directors. In parochial government the guardians of the poor, &c., are called the Board of Guardians, &c. The word *bureau* in France is an equivalent expression.

BOAT. [GUN-BOAT, LIFE-BOAT, MORTAR-BOAT, &c.]

BOATSWAIN, a warrant officer in a ship of war who has the care of the rigging, cables, cordage, anchors, sails, boats, flags, colours, and other stores, which are committed to his charge by indenture from the surveyor of the navy. One of the chief duties which devolve upon this officer is to attend to the rigging of the vessel, which he is charged to inspect every morning; not only to observe that everything is properly fitted and arranged in its place, but to see that all things are in good condition, to remove whatever may be judged unfit for service, and to supply whatever may be deficient. He cannot however cut up or otherwise appropriate any cordage or canvas for the public uses of the ship without a written order from the captain, and under the inspection of the master. His instructions inculcate the utmost frugality in the use of the stores intrusted to him; and at the end of a voyage he must present to the surveyor of the navy minute accounts, previously audited and vouched by the captain and master, of the purposes to which all the stores in his department have been applied, or of the circumstances under which they may have been lost, stolen, misapplied, or returned to the dock-yard. He cannot receive his pay till his accounts have been approved.

In this department the boatswain is much under the control of the master; his more exclusive function is that superintendence and control which he exercises over the men. He summons the crew to their duty, assists with his mates in the necessary business of the ship, and relieves the watch when its time expires. His calls on the crew are made by a silver whistle of a peculiar construction, well-known as the "boatswain's call." He must observe that the men attend when called, and that they properly perform their duties; and he is enjoined to observe, "that the working of the ship be performed with as little noise and confusion as possible." The boatswain is a sort of provost-marshal in the ship, inflicting such punishments as may be awarded by the captain or by court-martial. These latter functions he performs through his mate, whose office is perhaps the most unpopular in the navy. The boatswain is the examiner of seamen and boys before they attain higher ratings, and is indeed considered in all things to be a thoroughly practical and finished seaman. His influence in a ship is immense, and the discipline of the crew and the comfort of the ship depend greatly on his tact and temper, his firmness and judicious forbearance. Hence his position (together with that of the other warrant officers) is attracting the attention of the authorities, and measures are already in contemplation to restore his position which, till 1844, was next in rank below second masters, and also his pension, which was discontinued in 1830. Boatswains and the other warrant officers [WARRANT OFFICERS] frequently at sea keep a lieutenant's watch, and henceforward they will, for highly meritorious conduct, be allowed to hold commissions in her Majesty's fleet if competent to pass a certain examination, and the Admiralty allows the sum of 100*l.* to cover the expense of outfit on such occasions. The sea pay of a boatswain varies from 4*s.* 9*d.* to 6*s.* 7*d.* per day, according to his class and rate of ship. The number of his mates varies from four to one, according to the size of the vessel, and their pay is that of a chief petty officer.

(*Regulations and Instructions relating to her Majesty's Sea Service; Harris's Lexicon Technicum: Table of Naval Allowances, &c.*)

BOBBEN-NET AND LACE. [LACE.]

BOCLAND, land held by book or charter. The two great distinctions of lands in the Anglo-Saxon times were those of boc-land and folc-land. The former means land which had been severed from the folc-land, and converted into an estate of perpetual inheritance. Folc-land, on the other hand, was the property of the community. Sir Henry Spelman describes folc-land as "*terra popularis, quæ jure communi possidetur—sine scripto.*" ('*Glossar.*' v. Folcland.) In another place (v. Bocland) he says, "*Prædia Saxones duplici titulo possidebant: vel scripti autoritate, quod Bocland vocabant—vel populi testimonio, quod Folcland dixerent.*" Folcland might be held in severalty or occupied in common, but could not be alienated in perpetuity. Where held in severalty it was probably granted by the folcgemot or district court, or bestowed as a reward for some public service, and was subjected to certain burdens beyond the military service and the maintenance of fortresses, bridges, and roads, exacted from all landed possessions, such as repairing the royal vills, furnishing carriages and horses to the sovereign and other great men on their journey, receiving travellers, &c. (Lapenberg's '*Geschichte von England*;' J. M. Kemble's '*Saxons in England*;' and his '*Codex Diplomaticus Ævi Saxonici*,' Introduction.)

The author of 'A Dissertation on the Folclande and Boclande of the Saxons,' 4to., Lond. 1777, says, "the Boclande and Folclande are first discovered in an ordinance of Æthelbert, which informs us that the country was divided into two portions, one of them more immediately appertaining to the King and his Thains, the other under the jurisdiction of the Earl, who was annually elected by the freemen of every shire, and was denominated Eorl, Ealdorman, or Gerefa, and in latter times Greve, or Reve; he it was that convened the Folcmote, which was composed of the possessors of Folclande, and together with the bishop administered the oath of allegiance to the freemen, over whom he presided when they sat in their judicial capacity, and whose decrees it was his duty to enforce."

Mr. Allen, in his 'Inquiry into the Rise and Growth of the Royal Prerogative in England,' 8vo. Lond., 1830, goes more at length into this subject: he says that Bocland might belong to the church, to the king, or to a subject. It might be alienable and devisable at the will of the proprietor. It might be limited in its descent, without any power of alienation in the possessor. It was often granted for a single life or for more lives than one, with remainder in perpetuity to the church. It was forfeited for various delinquencies to the state. Bocland, moreover, was released from all services to the public, except those which were comprised in the phrase "trinoda necessitas," which were said to be incumbent on all persons: these were the contributing to military expeditions, and to the reparation of castles and bridges. Bocland also might be held by freemen of all ranks and degrees. A ceorl might possess bocland and perform for it military service to the state. If he had five hides of bocland, with the other requisites demanded by law, he was entitled to the privileges of a Thegn. (Wilkin's 'Leg. Anglo-Sax.' pp. 70, 71.) Gesiths (companions or partners) might receive grants of bocland. (Hickes, 'Gramm. Anglo-Sax.' p. 139; Bedæ, 'Hist. Eccl.' cura Smith, p. 786.) Thegns might also possess bocland. But the estate of a thegn in bocland must not be confounded with the thegn-lands which he held, by a beneficiary tenure from the king or from a private lord, for military service. Thegn-lands held of the king or state are repeatedly mentioned in Domesday; and the Saxon laws carefully distinguish the bocland possessed by a thegn, from the land given him by his hlaforð (or lord). ('Leg. Can.' p. 75.) It is probable that thegn-lands were originally granted for life, as beneficiary lands were on the Continent; but before the end of the Saxon period, the possessions given to a man by his hlaforð descended in certain cases to his children. (Ibid.) The estates of the higher nobility consisted chiefly of bocland. Bishops and abbots might have bocland of their own, in addition to what they held in right of the church. The Anglo-Saxon kings had private estates of bocland; and these estates did not merge in the crown, but were devisable by will, alienable by gift, or sale, and transmissible by inheritance in the same manner as bocland held by a subject.

When bocland was created, it was released from the burthens to which folcland was subjected, and the proprietor, unless fettered by the original grant, or by a subsequent settlement of the estate, appears to have had an unlimited power to dispose of it as he chose (Somner's 'Gavelkynd'); in the exercise of that power he might transfer it by grant or bequeath it by will, in such quantities, for such periods, and on such conditions as he was pleased to appoint. If conveyed by a written instrument, whatever might be the stipulations annexed to the grant, the land was still denominated bocland. (See Heming's 'Chartul.' and Smith's 'Bede.') When once severed from the folcland, or property of the community, an estate retained the name of bocland, whatever were the burthens and services imposed on it, provided it was alienated by deed. When transferred on condition of reversion, it seems to have been called *lænland*. This appears from a transaction recorded in the Chartulary of Worcester. (Heming, p. 158; see also *ibid.* pp. 204, 205.) We are there told that Archbishop Oswald granted to Ælfsige a tenement in Worcester, with the croft attached to it, for three lives, to be held as amply in the form of bocland as it had been held before in the form of *lænland*. *Lænland* might be an estate for life, or it might be held at will; and if the possessor was convicted of felony it reverted to the donor. (Lappenberg and Kemble.)

Bocland, says Mr. Allen, when alienated by grant or will, might be free, or in the seignory of some church, manor, or individual. It might be subjected to a variety of conditions, but it must be conveyed by a written instrument, though the delivery was symbolised by a staff, an arrow, a drinking horn, &c.; and a great part of the charters in the 'Codex Diplomaticus Ævi Saxonici' relate to the changing of folcland into bocland. Tenants of bocland might be persons of the same description with the lowest and most dependent of the occupiers of folcland. The only difference between them seems to have been, that the tenants of folcland held their lands directly from the public authorities of the state, while the others held their land of some proprietor, to whom it had been previously granted as a private inheritance. The villain of later times and the copyholder of the present day are not derived from the one more than from the other.

Bocland might be forfeited for various offences, and when forfeited, it escheated to the king, as the representative of the state. ('Leges Æthelredi Regis,' 2; 'Leg. Cnuti,' 12, 75; 'Text. Roff.' pp. 44, 136; Hickes, 'Diss. Ep.') Land held of a subject, when forfeited for the same delinquency, escheated to the lord. ('Leg. Cnuti.') When bocland was granted on lives, it was usual to insert a clause in the charter,

ARTS AND SCI. DIV. VOL. II.

declaring that whatever offence the tenant might commit, his land should revert without forfeiture to the grantor. ('Monasticon Angl.' vol. iii.)

From the view that has been taken of the distinction between folcland and bocland, it follows that the folcland, or land of the community, like the fisc of the Continental nations, was the fund out of which the boclands, possessions or estates of inheritance, were carved. At what time the folcland, or land of the public, began to be converted into bocland we are not informed. It was probably soon after the establishment of the Saxons in England; for though a more rude and uncultivated people than the nations which had enjoyed greater opportunities of intercourse with the Romans, they must have found private property in land among the Britons whom they expelled or subdued, and could not long remain insensible to the advantages arising from it. Certain it is, that in one of the earliest charters giving land to the Church, it is implied, though not expressly asserted in the grant, that the land contained in the donation had been previously the private property of the donor. (Between A.D. 665 and 694, see Smith's 'Bede,' p. 748.) But though commenced at an early period, the conversion of folcland into bocland seems to have been slowly and gradually effected. Every charter creating bocland is a proof that the land had formerly been folcland. A charter of Archbishop Wilfred, who died about 830, asserts in direct terms, that the land which he gives away had never been any man's bocland before it became his, and appeals to general practice, whether a proprietor of bocland might not sell it or dispose of it as he pleased. (Somner's 'Gavelkynd'.)

Folcland being the property of the community, could not be converted into bocland except by an act of government. In early times this was probably done in the gemot or public assembly of the tribe, as temporary allotments to individuals were made in the gemot or assembly of the district. But when the king came to be considered as the representative of the state, all charters of bocland ran in his name, and appeared to emanate from his bounty. The power of creating allodial property, by which was meant an estate of inheritance, is enumerated in the 'Textus Roffensis,' cap. xxvii., among the prerogatives of the crown. But though bocland could not be created without the authority of the king, it was not in his power to convert folcland into bocland without the consent of his witan, principes, seniores, optimates, magnates, or other persons, by whatever name they were called, who assisted him in the administration of his kingdom. There is hardly a Saxon charter creating bocland which is not said to have been granted by the king with consent and leave of his nobles and great men. If that consent was withheld, his grant was invalid.

When the king became the representative of the state, the folcland, or land of the public, began to be called and considered his property. It was his land in the same sense that the servants of the public were his servants, the laws his laws, and the army his army. In his politic capacity he was the state, and whatever belonged to the state belonged to him. If folcland was assigned to any one for life, or for a shorter term, it was given by his authority, and apparently for his service. When it was converted by charter into bocland, or land of inheritance, the deed was executed in his name, and though the grant was of no validity without the concurrence of his witan, the donation seemed in form the spontaneous act of his munificence.

In fact, there seems but little doubt that the folcland of our Saxon ancestors, which, in contradistinction to bocland, has so long puzzled English antiquaries, was no other than the public land, which in the lapse of time ultimately received another appellation, that of Terra Regis, or crown land. The term Bocland, as has been already noticed, was appropriated to such portions as from time to time had been severed from it, and granted out by written instrument. These severances increased rapidly towards the close of the Anglo-Saxon period. Mr. Kemble says, "I should imagine nearly every acre of land in England had become bocland." As in many cases, particularly in grants to the Church, even the usual burthens for military defence were remitted, it evidently enfeebled the nation, and in some degree accounts for the successes of the Danes and Normans in their invasions.

It is remarkable that in the Domesday Survey the term *Bocheland* occurs but once in its proper acceptation ('Domesd.' tom. i. fol. 11 b.): though as the name of a place it frequently occurs. (See Ellis's 'General Introd. to Domesd. Book,' vol. i. p. 230, note.) Mr. Allen, 'Inquiry, &c.' observes that numerous entries in Domesday distinguish lands which in Saxon times must have been bocland into free lands and lands in seignory. (See 'Domesd.' tom. i. fol. 72 a, col. 2, 80 a, col. 1, 84 b, col. 2, &c.)

BODLEYAN, or BODLEIAN LIBRARY. The public library of the University of Oxford was founded in 1597 by Sir Thomas Bodley, in the year in which he retired altogether from public employment [BODLEY, SIR THOMAS, in BIOG. DIV.]

The first public library in Oxford was established in what was then called Durham (since Trinity) College, by Richard de Bury, or Aungerville, bishop of Durham and lord treasurer of England, in the time of Edward III. He died in 1345, and left his books to the students of Durham College, who preserved them in chests, until the time that Thomas de Hatfield, his successor in the see of Durham, built the library in 1370. Chalmers, however, in his 'History of the Colleges, Halls, and Public Buildings of Oxford,' vol. ii. p. 458, says, it is not

very clear whether this was a public library in the usual meaning of the term, or one restricted to the use of the monks of Durham College only.

The next we read of was called Cobham's Library, which would have been the first, if Thomas Cobham, bishop of Worcester, had lived to have executed his own purpose. About the year 1320, he began to make some preparations for a library over the old Congregation-House, in the North Churchyard of St. Mary's; but dying soon after, little progress was made in the work till 1367, when his books were deposited in it, and the scholars permitted to consult them on certain conditions. But the property of the site being contended between the University and Oriel College, the dispute was not finally determined till 1409, when the room was fitted up with desks, windows, &c., by the benefactions of King Henry IV., of his four sons, Henry, Thomas, John, and Humphrey, of Thomas Arundel archbishop of Canterbury, Philip Repindon bishop of Lincoln, Edmund earl of March, and Richard Courtney chancellor of the University, in whose time it was completed about the year 1411. This appears to have been the first public library, and continued in use until 1480, when the books were added to Duke Humphrey's collection, for the reception of which a library-room had been completed.

Humphrey, surnamed the Good Duke of Gloucester, was the real founder of the library which was restored and refounded by Sir Thomas Bodley. The number of books given by Duke Humphrey is variously represented. Wood ('Hist. and Antiq. of the Univ. of Oxford,' vol. ii. pt. ii. 4to, Oxf. 1796, p. 715) says the different treatises amounted to six hundred; only one specimen at present remains, a manuscript in folio of Valerius Maximus, enriched with the most elegant decorations, and written in Duke Humphrey's age, evidently with the design of being placed in his sumptuous collection. The rest of the books, which, like this, being highly ornamented, and looking like missals, were supposed to convey ideas of Popish superstition, were destroyed or removed by the visitors of the university in the time of Edward VI., whose zeal was equalled only by their ignorance. A manuscript commentary on Genesis, by John Capgrave, belonging to Duke Humphrey's library, is still preserved in that of Oriel College, Oxford; and one, if not more manuscripts, formerly belonging to the collection, are in the British Museum; most of them, at the end, had usually this inscription written in the duke's own hand, "C'est livre est a moy Humfrey Duc de Gloucestre." Before the year 1555 the Duke of Gloucester's Library was totally despoiled of its contents, and the desks and benches ordered to be sold: the room continued empty until restored by Sir Thomas Bodley.

It was in 1597 that Sir Thomas Bodley set himself the task of restoring the public library. With this view he sent a letter from London to the vice-chancellor Dr. Ravis, dean of Christ Church, offering to restore the building, and settle a fund for the purchase of books, as well as the maintenance of proper officers. This offer being gladly accepted, he commenced his undertaking by presenting a large collection of books purchased on the Continent, and valued at 10,000*l*. Other collections and contributions were sent in, by his example and persuasions, from various noblemen, clergymen, and others, to such an amount, that the old building was no longer sufficient to contain them. He then proposed to enlarge the building; and the first stone of the new foundation was laid with great solemnity on the 17th of July, 1610, and so amply promoted by his liberality, as well as by the benefactions of many eminent persons, that the University was enabled to add three other sides, forming the quadrangle and rooms for the schools, &c. Bodley did not however live to see even the wing he had commenced finished, having died in 1612, the year before its completion.

When Sir Thomas had succeeded in enriching his collection, probably far beyond his expectation, he drew up a body of statutes, which have been since incorporated with those of the university. According to them, the librarian is to be a graduate, unmarried, and without cure of souls; and to be allowed deputies or assistants. One or two points in these regulations have been since altered; the librarian is allowed to marry, and he can hold parochial preferment with his librarianship. The revenues for the maintenance of the library are intrusted to the vice-chancellor and proctors for the time being; and the vice-chancellor and proctors, the three professors of divinity, law, and physic, and the two regius professors of Greek and Hebrew, are appointed visitors.

The first catalogue of the printed books of the Bodleian was published in 4to, in 1605, by Dr. Thomas James, Sir Thomas Bodley's first librarian. It was dedicated to Henry Prince of Wales; and the books were classed in four faculties, divinity, medicine, jurisprudence, and arts, completed by an index of authors' names. A more extensive catalogue, in an alphabetical form, was published by Dr. James in 4to, Oxford, 1625; and another catalogue, which had been compiled by him, of works in the Bodleian, printed and manuscript, in interpretation of the Scriptures, was printed in a thin 4to at Oxford in 1635. 'A Nomenclator of such Tracts and Sermons as have been printed or translated into English upon any place or books of Holy Scripture; now to be had in the most famous Library of Sir Thomas Bodley in Oxford,' was also printed in 18mo in 1642, by John Veneuil.

In 1674 a new catalogue of the printed books of the Bodleian was published in a folio volume, under the care of Dr. Thomas Hyde;

and another, of the manuscripts, distinguishing the different collections, was inserted in the general Catalogue of the Manuscripts of England, folio, 1697. A still more extensive catalogue of the printed books was published in two volumes, folio, in 1738, which was thought so sufficiently perfect in its day, that almost every college library in the university had a copy interleaved, to mark off the books in the catalogue which they themselves possessed, and to insert additions. This is the last general catalogue which has been published of the books in the Bodleian Library; but from the immense increase of the collection it has become but of little use. Another was undertaken some years ago, and had proceeded, under the direction of the present librarian, Dr. Bandinel, to some extent in the printing; but the publication was eventually abandoned.

A few catalogues of particular portions of the Bodleian collections have been published at different times. Dr. Uri printed the first part of a catalogue of the Oriental manuscripts in folio, in 1787; which was continued in 1821, in a catalogue of the Arabic manuscripts, prepared by Mr., afterwards Dr. Alexander Nicol. After the acquisitions made at the Pinelli and some other sales, a small octavo volume, entitled 'Notitia Editionum quoad libros Hebr. Gr. et Lat. quæ vel primariæ, vel Sæc. xv. impressæ, vel Aldinæ, in Bibliotheca Bodleiana adservantur,' was published in 1795: another catalogue, entitled 'Codices Manuscripti et Impressi, cum Notis Manuscriptis, olim D'Orvilliani, qui in Bibliotheca Bodleiana adservantur,' was printed by Mr. Gaisford, afterwards dean of Christ Church, in 4to, 1806; and the first part of another catalogue, of the manuscripts collected in the East by Dr. E. D. Clarke, and purchased from him for the Bodleian, was published also by Mr. Gaisford in 4to, 1812; followed by a second part in 1815, containing the Oriental MSS., edited by Mr. Nicol. In 1814, a catalogue of the books relating to British (including Welsh, Scottish, and Irish) topography, and Saxon and northern literature, bequeathed by Richard Gough, Esq., was printed at the Clarendon press by Dr. Bandinel. The curators of the Bodleian have for many years published, or rather printed and distributed, annual alphabetical catalogues of its acquisitions in the department of printed books, for the information of the university.

A catalogue of the coins in the cabinet of the Bodleian was published by Mr. Francis Wise in 1750, in folio, illustrated by numerous plates, under the title of 'Catalogus Nummorum Antiquorum in Scriniis Bodleianis reconditorum cum Commentario.'

An annual speech in praise of Sir Thomas Bodley was founded in 1681, by Dr. John Morris, canon of Christ Church; the speaker to be nominated by the dean of Christ Church, and confirmed by the vice-chancellor. These speeches are delivered at the visitation-day of the library, November the 8th.

It would be impossible to enumerate here the many important additions, in books and manuscripts, made to this library by its numerous benefactors, or to give even a superficial sketch of its ample contents in every branch of science and learning. Among the earliest benefactors were Robert Devereux Earl of Essex, Thomas Sackville Lord Buckhurst and Earl of Dorset, Robert Sidney Lord Sidney of Penshurst, Viscount Lisle and Earl of Leicester, George Carey Lord Hunsdon, William Gent, Esq., Anthony Browne Viscount Montacute, John Lord Lumley, Philip Scudamore of London, Esq., and Lawrence Bodley, younger brother to the founder. The contributions of all these persons were made before the year 1600.

In 1601, collections of books and manuscripts were presented by Thomas Allen, some time fellow of Trinity College, Thomas James, the first librarian, Herbert Westphaling, bishop of Hereford, Sir John Fortescue, knight, Alexander Nowell, dean of St. Paul's, John Croke, recorder of London and chief-justice of the Common Pleas, and Nicholas Bond, D.D., president of Magdalen College.

The most extensive and important collections however are those of the Earl of Pembroke, the celebrated John Selden, Archbishop Laud, Sir Thomas Roe, Sir Kenelm Digby, General Fairfax, Dr. Marshall, Dr. Barlow, bishop of Lincoln, Dr. Richard Rawlinson, Mr. St. Amand, Bishop Tanner, Browne Willis, Thomas Hearne, Mr. Nathaniel Crynes, and Mr. Godwin. The library bequeathed by Richard Gough, Esq., which came to the Bodleian in 1812 (the catalogue of which has been already noticed), is one of the most perfect series of English topographical works ever formed, and is particularly rich in topographical manuscripts, prints, drawings, and books illustrated by the manuscript notes of eminent antiquaries. The last collections of great importance bequeathed to the Bodleian have been those of Edmond Malone, Esq., in 1812, and of Francis Douce, Esq., in 1834, but it is continually being added to by smaller bequests and donations.

The Bodleian Library was first opened to the public on November 8th, 1602, and by the charter of mortmain obtained of King James, Sir Thomas, then lately knighted by him, was declared founder; and, in 1605, Lord Buckhurst, earl of Dorset and chancellor of the University, placed the bust of Sir Thomas in the library. Since the year 1786 a fund of more than 400*l*. a year has been established for the purchase of books. This arises from a small addition to the matriculation fees, and a moderate contribution annually from such members of the university as are admitted to the use of the library, or on their taking their first degrees; to which is to be added the privilege of claiming as a matter of right under the copyright act, a copy of every book printed in Great Britain and Ireland.

The principal librarians since the foundation by Sir Thomas Bodley, have been,—1. Thomas James, fellow of New College, 1598; 2. John Rouse, fellow of Oriel, 1620; 3. Thomas Barlow, fellow, afterwards provost of Queen's, bishop of Lincoln, 1653; 4. Thomas Lockey, student, and afterwards canon of Christ Church, 1660; 5. Thomas Hyde, of Queen's College, afterwards Laudian professor of Arabic, regius professor of Hebrew, and canon of Christ Church, 1665; 6. John Hudson, of Queen's, afterwards principal of St. Mary Hall, 1701; 7. Joseph Bowles, fellow of Oriel, 1719; 8. Robert Fysher, fellow of Oriel, 1726; 9. Humphrey Owen, fellow and afterwards principal of Jesus College, 1747; 10. John Price, B.D., of Jesus College, afterwards of Trinity, 1768; 11. Bulkeley Bandinel, D.D., late fellow of New College, 1813, the present librarian.

All members of the university who have taken a degree are admitted to study in the library: no books have ever been suffered to be taken from it. Literary persons, either native or foreign, are also allowed, on being properly recommended, to read and take extracts from the books in this collection. The library is open between Lady-day and Michaelmas from nine in the morning till four in the afternoon; and during the other half-year from ten till three. It is closed on Sundays and state holidays; from Christmas-eve to the 1st of January inclusively; on the feast of the Epiphany; from Good Friday to Easter Tuesday inclusively; on the days of Encænæ and Commemoration; seven days immediately following the 1st of September, and eight days preceding the visitation of the library, which takes place on the 1st of November. On all other holidays it is opened immediately after the university-sermon.

BOHEIC ACID. An astringent acid said to be contained in black tea. Its existence is, however, very doubtful.

BOHEMIANS. [GIPSIES.]

BOIL, called also phlegmon and furunculus, from *furo*, to rage, on account of the violence of the heat and inflammation attending it. A boil is a tumour of an inflammatory nature seated in the skin and in the cellular tissue beneath it. It may occur on any part of the external surface of the body, and it is of various sizes from the bulk of a pea to that of a pigeon's egg, which latter it seldom exceeds. The tumour is circumscribed, prominent, hard, of a conical figure, the base of the cone being broad, deep, and intensely red. The whole surface of the tumour is exquisitely tender, and is commonly attended with a very painful sense of burning and throbbing. Its natural termination is in suppuration, that is, in the formation of the matter called pus, but the progress is always slow and the process itself imperfect, the pus formed being generally scanty and never healthy. Only a few drops of purulent matter, commonly mixed with blood, flow from the most prominent or pointed part of the tumour, while there remains behind the germ, or what is commonly called the *core*, a purulent sloughy substance, so thick and tenacious that it appears like a solid body. When this core is discharged, the pain entirely ceases and the opening heals spontaneously, but the removal of this is indispensable to the cure of the disease.

The complaint is never attended with danger, and seldom accompanied with fever, excepting when the tumour is seated over some peculiarly sensitive part, or when (as occasionally happens) several tumours occur at the same time in several places. Under such circumstances, in adults of irritable habits, and almost always in children, a good deal of constitutional disturbance is excited.

The disease, though local in its seat, is constitutional in its origin, and affords a good example of a class of maladies, a very large one, which are limited in their seat to a small spot, perhaps on the external surface of the body, but which have their source in the disturbance of some internal organ or of the system in general.

The internal organs, the derangement of which most commonly produces this external disease, are those which belong either to the digestive or to the excrementitious systems, or to both. In consequence of the disordered state of these organs, either perfectly pure chyle is not eliminated, or the blood is not properly depurated, or excrementitious matter is re-absorbed into it, the circulating fluids become contaminated, and the result is the irritation and inflammation of the surface.

The rational and successful treatment of this disease must therefore combine two objects,—the removal of the local malady, and the correction of the disordered state of the system in which it has its origin. The first intention is accomplished by assisting the process of suppuration, which, as already stated, is always tardy and imperfect, but must be rendered complete before the malady can be removed. The proper external applications are repeated emollient poultices, as those made of linseed meal, which may be mixed, when the pain is violent, with conium, hyoscyamus, or opium. The suppuration is so imperfect that even the diligent use of poultices seldom causes the tumour to burst spontaneously with an aperture sufficiently large to allow of the discharge of the pus, together with the sloughy cellular substance that forms the core. As soon as any matter can be per-

ceived in the tumour a free opening should therefore be made into it with a lancet, and as much of the matter and slough as can be forced out of it by tolerably firm pressure should be removed.

While recourse is had to these external applications, it is indispensable to correct the disordered state of the organs. This may be effected by a course of mild alterative medicines: the bowels should always be freely opened at first, and then *regulated* by gentle unirritating laxatives. At the same time strict attention should be paid to the diet, which should be of the plainest and simplest nature, nutritive but not stimulating, consisting of a moderate portion of plainly cooked animal food, without fermented liquors, without pastry, and without fruit.

BOILER is the general name applied to vessels, whether close or open, in which fluids are exposed to heat for the purpose of ebullition or evaporation; but the term is most commonly applied to the close vessels used for the generation of steam. Such boilers, to lessen the danger of explosion, are almost invariably made of wrought metal, which, if burst, will tear rather than fly to pieces, as cast metal would do; and the plates made for the purpose are formed of the best and toughest metal, and rolled or wrought with peculiar care. Engineers differ as to the comparative merits of iron and copper as a material for steam-engine boilers. Most however admit that iron, when of good quality, has the greatest cohesive strength, although the greater uniformity of texture in sheet-copper renders it safe to construct copper boilers of less thickness than those of iron, to withstand a given pressure. Further than this, supposing an explosion to occur with a copper boiler, it is likely only to produce a rent or tear in the metal, while an iron boiler, even though wholly of wrought plates, is frequently blown to pieces. The cost of copper is about four times that of iron, but as, owing to its far more rapid transmission of heat, a copper boiler may be made considerably smaller than an iron one to produce the same quantity of steam, and may therefore be still further reduced in thickness and weight without impairing its strength; the cost of a copper boiler is nearer twice than four times that of an iron boiler of equal evaporating power; and, as a set-off to this increased expenditure, the value of the old copper, when the boiler is worn out, is equal to three-fourths of its original cost, while an old iron boiler is worth little more than the cost of removal.

The various kinds of boiler employed in manufacturing operations will be treated of under the heads of the different purposes for which they are employed; as STEAM-ENGINE, STEAM-CARRIAGE, STEAM-VESSEL, SUGAR BOILING, WARMING AND VENTILATION, &c.

BOILING OF LIQUIDS. A liquid is said to boil when bubbles of the vapour of the liquid are formed, and, by reason of their lightness, rise to its surface and escape. The circumstances conditioning the formation of such bubbles are four:—1. The nature of the liquid in respect to chemical constitution. 2. The temperature to which it is exposed. 3. The pressure upon its surface, and consequently throughout its mass. 4. The magnitude of the force of adhesion between the liquid and the substance with which it is in contact.

An example will illustrate this. A glass basin containing boiled distilled water may be gradually heated to 216° Fahr. without the water boiling. We have then the four above-named conditions in the following state:—

1. Oxygen and hydrogen, in the proportion of 8 to 1 (HO).
2. A temperature of 216° Fahr.
3. The existing pressure of the atmosphere (say 15 lbs. per square inch).
4. The adhesion between water and glass.

By altering any one of these conditions, boiling or ebullition may be produced. Thus: 1, if ether, (C_4H_6O), be substituted for water, the ether will boil; 2 if, the temperature be raised a few degrees the water will boil; 3, if, the basin being put under the air-pump, the air be exhausted, the pressure of the atmosphere being thereby diminished, the water will boil; 4, if the glass basin be replaced by a copper one, the water will boil.

Again, respecting the above-mentioned four conditions: 1, two or more chemically dissimilar liquids may boil at the same temperature, under the same pressure, and in the same vessels; 2, one and the same liquid cannot boil at two different temperatures under the same pressure and in the same vessel; 3, one and the same liquid cannot boil at the same temperature under two different pressures in the same vessel; 4, it is probable, although not certain, that one and the same liquid cannot boil at the same temperature and under the same pressure in two vessels whose internal surfaces so differ in texture or constitution as to possess different adhesion to the liquid. But as both physical texture and chemical constitution affect the boiling of a liquid independently, it follows that the same liquid may boil at the same temperature and under the same pressure in vessels of unlike chemical constitution, provided that their surfaces are so unlike in texture also as to counterbalance their chemical dissimilarity. Thus, water boils at a lower temperature in metallic vessels than in glass ones. It boils also in vessels whose internal surfaces are rough at a lower temperature than in smooth ones. Hence, in a smooth metallic vessel it may boil at the same temperature and under the same pressure as it does in a rough glass one.

We must examine one by one the above-mentioned four circumstances which determine the boiling of a liquid, bearing in mind that

ebullition is *affected* by the chemical nature of the liquid (but the law according to which such chemical constitution is connected with the boiling has been established in only a comparatively few cases), and that it is *induced* by increase of temperature, diminution of pressure, and diminution of adhesion between the boiling liquid and the substance with which it is in contact.

A liquid is said to be perfectly volatile when it can be boiled away without chemical change. If heat be applied to a vessel containing a single such volatile liquid, its temperature will gradually rise until it reaches a certain point (dependent upon the four conditions) at which boiling commences; that is, at which the pressure of the air is overcome by the expansive force of the vapour of the liquid. If the heat be continually applied after this point is reached, the liquid is boiled off in the form of vapour, but to the last it retains the same temperature as that at which it commenced boiling,—a temperature which the vapour of the liquid also assumes. After the boiling has once commenced the external heat is expended, not in effecting a rise of temperature, but in converting the liquid into a vapour. Hence, the temperature at which one and the same volatile liquid boils is constant (the other two conditions being also constant), and that temperature is called the *boiling point* of the liquid under those conditions.

A liquid which is boiled in an open vessel is exposed to the pressure of the atmosphere, and its boiling is induced or retarded according as this pressure is less or greater. Thus, when the atmospheric pressure is small [BAROMETER], water boils at a lower temperature and in a smoother vessel than when it is great. Hence, in determining the temperature at which a liquid boils in an open vessel of fixed nature, reference must be had to the existing atmospheric pressure. Conversely, from the temperature at which a simple volatile liquid boils in an open vessel of fixed nature, the atmospheric pressure may be determined.

It follows from the above, that if exact comparison has to be made of the temperatures at which chemically different liquids boil, the determinations must be made when the liquids are subjected to the same atmospheric pressure, or the effect of change of pressure on the boiling point must be ascertained, and the corresponding correction made.

In the following table are found the boiling points of various liquids in contact with platinum wire, at the mean barometric pressure of 29.92 inches (760 millimètres). The temperatures are given on the Fahrenheit scale.

Substance.	Chemical Composition.	Boiling Point.
Protoxide of nitrogen	NO	— 157
Carbonic acid	CO ₂	— 108
Cyanogen	C ₂ N	— 7
Sulphurous acid	SO ₂	+ 12
Chloride of ethyl	C ₂ H ₅ Cl	+ 52
Ether	(C ₂ H ₅ O) ₂	92
Formate of methyl	C ₂ H ₃ OC ₂ HO ₃	97
Bisulphide of carbon	CS ₂	117
Acetate of methyl	C ₂ H ₃ OC ₄ H ₃ O ₃	131
Formate of ethyl	C ₄ H ₅ OC ₂ HO ₃	
Methylic alcohol	C ₂ H ₅ OHO	138
Propionate of methyl	C ₂ H ₃ OC ₆ H ₅ O ₃	167
Acetate of ethyl	C ₄ H ₅ OC ₄ H ₃ O ₃	
Formate of propyl	C ₆ H ₇ OC ₂ HO ₃	172
Ethylic alcohol	C ₄ H ₅ OHO	
Benzol	C ₁₂ H ₆ H	176
Butyrate of methyl	C ₂ H ₃ OC ₈ H ₇ O ₃	199
Propionate of ethyl	C ₄ H ₅ OC ₆ H ₅ O ₃	
Acetate of propyl	C ₆ H ₇ OC ₄ H ₃ O ₃	
Formate of butyl	C ₈ H ₉ OC ₂ HO ₃	
Propylic alcohol	C ₆ H ₇ OHO	207
Formic acid	C ₂ HO ₃ HO	210
Water	HO	212
Toluol	C ₁₀ H ₇ H	219
Butylic alcohol	C ₈ H ₉ OHO	241
Acetic acid	C ₄ H ₃ O ₃ HO	244
Xylol	C ₁₀ H ₈ H	262
Bibromide of ethylene	C ₂ H ₄ Br ₂	266
Amylic alcohol	C ₁₀ H ₁₁ OHO	275
Propionic acid	C ₆ H ₅ O ₃ HO	279
Bibromide of propylene	C ₃ H ₆ Br ₂	293
Cumol	C ₁₀ H ₁₁ H	306
Butyric acid	C ₈ H ₇ O ₃ HO	311
Oil of turpentine	C ₂₀ H ₁₅ H	315
Bibromide of butylene	C ₄ H ₈ Br ₂	320
Valerianic acid	C ₁₀ H ₉ O ₃ HO	347
Cymol	C ₂₀ H ₁₃ H	349
Sulphur	S	608
Sulphuric acid	SO ₃ HO	619
Mercury	Hg	680

An examination of this table points out the existence of a certain relation between the chemical constitution of some liquids and their boiling points at the same pressure. When two liquids, belonging to the same chemical type, so differ from one another that the one contains a molecule more of C₂H₂ than the other, the boiling point of the first is often 34°·2 Fahr. above that of the second. Thus the boiling points of formic, acetic, propionic, butyric, and valerianic acids increase by the successive increment of 34°·2 Fahr., as do those of

their corresponding alcohols, namely, methylic, ethylic, propylic, butylic, and amylic. Moreover the compounds resulting from the union of the above acids with the radicals of the various alcohols follow the same law. For not only are the boiling points of butyrate of methyl, propionate of ethyl, acetate of propyl, and formate of butyl, the same (the increase of 34°·2 Fahr. due to the additional C₂H₂ in the radical being exactly counterbalanced by the removal of C₂H₂ from the acid), but the bodies just named boil 34°·2 higher than propionate of methyl, acetate of ethyl, and formate of propyl: which again boil 34°·2 higher than acetate of methyl and formate of ethyl; while these latter boil 34°·2 above formate of methyl.

In the benzol series, however, this increment of C₂H₂ effects an elevation of 43°·2, while in the bromethylene series the increase is only 27°.

When an alcohol is converted into an acid by the exchange of two equivalents of hydrogen for two of oxygen, the boiling point is thereby raised 72°.

The above are the most perfectly developed of Kopp's laws relating to the connection between boiling point and chemical constitution. Although bodies belonging to the same chemical series have boiling points higher or lower according to their position in that series, yet liquids belonging to different series may have boiling points which, as far as experiment shows, perfectly coincide.

There appears to be no relation between the specific gravity of a liquid and its boiling point.

The chemically combined water in a liquid seems to have great influence upon its boiling point. This may be connected with the high latent heat of steam. Thus those alcohols whose boiling points are below 212° (ethylic) furnish, by the loss of water, ethers whose boiling points are still lower; while an alcohol which boils above 212° gives rise to an ether of higher boiling point than itself (amylic alcohol).

The following tables show the relation between the boiling points of various bodies and the pressures to which they are subjected: in other words they give the tension of the vapours of the bodies at different temperatures. (From Buff, Zammerer, and Kopp's 'Lehrbuch der physikalischen und theoretischen Chemie.') *t*° denotes the temperature Fahrenheit of the substance, and *h* the height of the column of mercury, in inches, which the vapour will support.

Formulae have been proposed to correct the pressure and the boiling point, and thus to serve to derive new values by interpolation. But all such formulae are more or less empirical, and cannot be relied on when the values sought are far from actually observed ones.

Contact with foreign bodies, as before stated, influences the boiling point of a liquid to some extent. Hence in comparing the boiling points of liquids, the latter must all be in contact with the same substance, generally platinum wire. When two liquids are perfectly miscible, the initial boiling point of their mixture is always above that of the liquid which has the lowest boiling point, and during the boiling it rises (more or less suddenly, according as the respective boiling points of the separate liquids are further apart or nearer), until the higher boiling point is reached, or nearly reached. But in a volatile liquid which, though not miscible with—still may be wetted by—water, the presence of water depresses the boiling point of the liquid, although the latter when dry would boil below 212° Fahr. This effect is probably due to the small quantity of disseminated water diminishing the cohesion of the liquid.

It is found that when two substances affect the boiling point of a liquid unequally, and both are present in it, the liquid will boil at the temperature due to the substance which depresses its boiling point most. Hence, in practice, in determining the boiling point of liquids,

instead of employing platinum vessels it is sufficient to introduce a piece of platinum into the liquid which is in a glass vessel.

On ascending mountains, by the consequent diminution of atmospheric pressure, and in proportion to it, water is found to boil at a lower temperature. Thus, on the summit of Mont Blanc, which is 15,650 feet above the level of the sea, Saussure found water to boil at 185°·8 of Fahrenheit. M. Wisse has recently determined the boiling point on Mount Pichincha, at an altitude of 15,940 feet, to be 185°·27 Fahr., whilst the barometer stood at 17·208 inches.

The effect of diminished pressure in lowering the boiling point may be readily exhibited: remove some boiling water from the fire, and ebullition soon ceases, but it is renewed by placing it under the receiver of an air-pump and quickly exhausting the air. Another and very simple method of producing the same effect is, to boil some water in a Florence flask, cork it while boiling, remove it immediately from the fire, and immerse it almost entirely in cold water, when the ebullition will recommence. This is occasioned by the sudden condensation of the steam which occupied the upper part of the flask, and the consequent formation of a vacuum; the existence of which is proved by the rush of air into the flask on removing the cork.

According to the Rev. Mr. Wollaston ('Phil. Trans.,' 1817), an elevation of 530 feet causes a diminution of 1° of Fahrenheit in the temperature of boiling water; but it will be observed that this determination, which is probably an accurate one, does not agree with the stated height of Mont Blanc, or the temperature at which water boils on its summit.

The Rev. Mr. Wollaston contrived an apparatus for determining elevations by the temperature of boiling water. It has been improved

and introduced under the name of the *Barometrical Thermometer*, made by Negretti and Zambra, to meet the requirements of travellers under circumstances where the mercurial barometer cannot be conveniently employed. The instrument is very portable, and consists of a very delicate thermometer, about 12 inches long, with a scale ranging from 180° to 212°, each degree being subdivided so as to show distinctly 0·1. There is also a copper boiler *c* attached to a small tripod stand; from the top of the boiler proceeds a three-draw telescopic tube, open at the top; this tube is surrounded by a second, similarly constructed, and screwed at the top of the boiler; the outer tube has two openings, one at the top through which the thermometer is inserted, passing down to within an inch of the water in the boiler, and supported by means of a cork or India-rubber washer; the second opening, forming an outlet for the steam, is shown at *g*. The object of the double tube is to ensure a steady boiling-point, which cannot well be obtained in open air experiments, where only a single tube is employed. *A* is a metallic spirit-lamp, surrounded with wire-gauze, to prevent the flame from being extinguished when experimenting in the open air. Each instrument is furnished with a carefully computed set of tables, from which may be obtained, by an easy calculation, the elevation corresponding to any observed boiling-point, between the temperatures of 180° and 212°. In using the apparatus, a sufficient quantity of water is poured into the boiler, through the small opening *f*, to fill it about one-third, when it is closed by means of a screw; the spirit-lamp is then applied, and when the water boils, the steam rises, surrounds the bulb and tube, descends between the two tubes, and issues from the opening at *g*. After a few seconds the mercury in the thermometer will rise and become stationary;

the degree indicated by it must then be noted, when, by reference to the tables, the elevation of the spot where the experiment has been performed may be obtained. The temperature of the air should be observed by a common thermometer at the same time.

Professor Robison states that fluids boil in vacuo at 140° lower than under atmospheric pressure; consequently, water so circumstanced will boil at 72°. Dr. Thomson informs us that he has seen water boiling briskly at 98° in Mr. Barry's apparatus for distilling oils in vacuo.

We have now described the circumstances under which the boiling point of water is lowered by diminishing the pressure; and we shall proceed to show how, by increasing the pressure, the boiling point is raised.

When water is heated in vessels from which the vapour cannot escape except by overcoming pressure, its boiling point becomes very much raised. This experiment may be made in *Papin's digester*, which is a strong iron or copper vessel, with a tight-fitting lid screwed down, and provided with a safety-valve, loaded with any proper quantity of

weights. In this way water may be heated to upwards of 400°; indeed, according to Muschenbroek, the temperature of water can be raised so as to melt tin, which fuses at 442°. A more convenient apparatus for this purpose was invented by the late Dr. Marcet. In this, the pressure is indicated by the height to which the steam raises a column of mercury, and the temperature is shown by a thermometer. It is represented in most treatises on Heat, but we may refer to Professor Miller's 'Chemistry,' vol. i. p. 227.

It should be observed that the temperature of the steam is always equal to that of the water from which it is generated. When however what is termed *high-pressure* steam is suffered to escape into the atmosphere, its temperature is greatly reduced, not merely on account of the cold air with which it comes into contact, but from the great expansion which it undergoes, and the consequent conversion of sensible into latent heat. In this case, it is so far from scalding like atmospheric steam, that it may be received upon the hand without feeling unpleasantly hot. When water is boiled in vessels which are not furnished with safety valves, or when from any accident they do not act or are overloaded, the strongest boilers burst with a tremendous explosion.

There are several circumstances which influence the boiling point of water besides those already noticed, though not to so great a degree. M. Gay Lussac found that water boiled exactly at 212° in a vessel made of tin plate, while in a glass one it acquired 214°; and he concluded that the boiling point varies according to the nature of the different vessels, and the state of their surfaces, in which the ebullition takes place, and consequently depends on their conducting power and the polish. It has been since ascertained that adhesion of the fluid to the surface of the vessel is the chief circumstance concerned in raising the boiling point. Thus, water may boil at 214° in a glass vessel, but if a pinch of iron filings be allowed to fall in, the adhesion will be diminished, and the temperature will sink to 212°. If the inner surface of the vessel be varnished with shell-lac, the temperature of 221° may be attained before the water boils; but the temperature of each gush of vapour is not more than 212°. The presence of a small quantity of oil in water has the effect of raising its boiling point 3° or 4°. The presence of air in liquids diminishes the adhesion, and greatly assists the evolution of vapour. By long boiling, so as to get rid of the whole of the air, Donny was able to raise its temperature in an open glass vessel as high as 360° Fahr., when it suddenly exploded into vapour with a loud report.

Dr. Bostock also found ('Annals of Philosophy,' vol. xxv. p. 196) that the boiling point of water is materially influenced by the presence of extraneous bodies. A saturated solution of common salt was placed over a lamp, and gradually heated up to 222°, when it boiled strongly; a test tube, containing water deprived of air by boiling, was plunged into the heated brine, and in a second or two it began to boil; the lamp was then withdrawn, and the brine soon ceased to boil, but the ebullition continued in the water for some time longer; it subsided at about 218° or 217°, but was constantly renewed by dropping in pieces of cedar wood. The brine was again placed over the lamp, and a test tube was plunged into it, containing a portion of water, together with a thermometer. The water in the tube did not begin to boil until the thermometer had risen to between 216° and 217°, when ebullition first commenced; the fragments of wood were then dropped in, and as usual very much increased the ebullition; and it was found that the water, kept at this temperature, had its ebullition promoted or suspended, according to the presence or absence of the extraneous bodies. Dr. Bostock concludes that in water the difference of boiling point occasioned by the circumstances described amounts to 4° or 5°, but in ether occasionally to 50° or more.

BOLE, ARMENIAN. [BOLE, in NAT. HIST. DIV.]

BOLETIC ACID. [FUMARIC ACID.]

BOLETUS, MEDICAL USES OF. Several different species, all confounded under the name *B. igniarius*, furnished the means of stanching the flow of blood from wounds. They were supposed to do this by an astringent property; and, being erroneously referred to the genus *Agaricus*, were termed *agaric*, which word is often used as synonymous with *styptic*. Boletus possesses, however, no peculiar power of arresting the flow of blood, but acts mechanically like a sponge, and favours the formation of a clot. It is now almost entirely disused by British surgeons, but in some cases it merits a preference over other means of closing a bleeding vessel. When it is to be used, it must be rubbed firmly between the hands, doubled, and applied over the orifice whence the blood proceeds, and bound down by a compress. It should not be removed till after twenty-four hours, and the clot should be softened with *cold*, not warm water. Though the German tinder seems to offer a convenient substitute for the prepared agaric in case of an emergency, it would be very improper to employ it, as the nitrate of potass or saltpetre in which it is steeped would irritate and inflame the edges of the wound. [AMADOU, in NAT. HIST. DIV.] The German tinder, however, forms a very excellent moxa. The different kinds of Boleti used as styptics were formerly designated *Agaricus chirurgorum*.

It is less on account of their uses than of their peculiar habitudes, that the Boleti merit our notice. In chemical composition, odour, and habitudes, they resemble animals more than vegetables. When cut into, some of them exhibit almost a muscular structure (*B. hepaticus*, or *Fistulina hepatica*), hence called by the French *langue de bœuf*. The

Boletus igniarius, when divided, has been stated by Professor Eaton to heal like a flesh-wound by the *first intention*, or complete reunion of its divided edges, scarcely exhibiting a cicatrix or trace of the injury. (Silliman's 'Journal,' vol. vi.) Nitrogen enters into their composition; and in regard to their relations with the atmosphere, they inhale oxygen, and exhale carbonic acid gas. The *Boletus luridus* has been ascertained to abstract twelve per cent. of oxygen from the atmosphere in twelve hours. ('Inquiry into the Changes which the Atmosphere undergoes when in Contact with certain Vegetables which are destitute of Green Leaves,' by M. F. Marcet; Jameson's 'Edin. New. Phil. Journal,' October, 1835.)

Boleti consist largely of *fungin*, with some boletic acid. Unlike most fungi, which grow rapidly and perish quickly, most of the Boleti grow very slowly, acquire a firm texture, and last perhaps 100 years if not exposed to much moisture. According to Sir William Jones, the *B. igniarius* is found in India, and used in nearly the same manner as in Europe. (Ainslie's 'Materia Medica Indica,' vol. i. p. 6.)

Boletus edulis (esculent Boletus, called in France Ceps) is not only extremely nutritious, but esteemed by the French an exquisite luxury. It is as susceptible of cultivation as the common mushroom. (See Dr. Badham, 'On the Esculent Mushrooms of England;' and Mrs. Hussey's 'British Mycology'.)

BOLOGNESE SCHOOL OF PAINTING. The historians of the fine arts employ the word school, as it is often used in reference to other pursuits, only to denote a similarity of opinion, aim, or practice among many individuals; but the term is so far true to its literal import, that the similarity of taste alluded to does not so much arise from the accidental coincidence of independent modes of thinking, as from some common influence, and generally from the example of one powerful mind. Nor does this always involve a defect of originality: in the complicated art of painting the advances to perfection were of necessity very gradual; the greatest masters were largely indebted to the labours of their predecessors, and each of them may thus be said to have sprung from a school as certainly as that he founded one. But when excellence was once approximated, originality seemed only compatible with a difference in the mode, since a difference of degree appeared to be no longer possible; and while the desire of novelty sometimes degenerated to caprice, and imitation ended in insipidity, the most plausible ambition seemed to be that which aimed at combining excellences not hitherto united in any one school. This was at least the professed object of the Caracci, the most celebrated among the Bolognese masters. It happens that this new effort took place in a school which had not before distinguished itself so greatly as the rest. The most brilliant epochs of art, south of the Alps, concur; the greatest masters having been contemporary with each other in the beginning of the 16th century. To this rule, which applies to Venice, Parma, Florence, and Rome, the Bolognese school is an exception, since it attained its comparative perfection nearly a century after the production of the finest works of Italian art.

The merits of the most distinguished later masters of the Bolognese school have been done ample justice to by many historians and biographers, but it must be confessed that the Florentine Vasari, who was naturally anxious to extol the genius of the Tuscan artists, sometimes betrays a disposition to undervalue or to vilify the earlier Bolognese painters whom he notices in his work, and he did not live to see the revolution which the Caracci produced. The chief historian of the Bolognese school, Malvasia (Felsina Pittrice), on the other hand, in his eagerness to defend his countrymen, has not unfrequently exaggerated their merits, and the two should be compared with the more impartial opinions of recent writers, among whom Lanzi, though again perhaps disposed to exalt his own Florence, will be found the most rational.

The arts of design were kept alive during the middle ages by mosaics and by illuminated manuscripts; the former were commoner at Rome and Ravenna than in the other Italian cities, but the art of missal-painting, which was practised wherever there was a monastery, seems to have attained some perfection at Bologna at an early period. The Franco Bolognese mentioned by Dante ('Purgatorio,' canto 11) as superior in this art to his master, Oderigi di Agubbio, it appears sometimes painted in larger dimensions, and the recorded dates of still earlier painters might enable Bologna to contend for the palm of antiquity not only with Florence but with Siena and Pisa. Franco, who has been called the Giotto of his school, is the supposed founder of the style of the Bolognese painters of the 14th century. Many of their now fading works exist in the church di Mezzaratta, a gallery, as it were, of ancient specimens which, as Lanzi remarks, is to this era of the Bolognese school what the Campo Santo at Pisa is to that of the early Florentines. In order, however, that this comparison should be just, it would be necessary to select corresponding dates; some of the works in the Campo Santo, as for instance those of Benozzo, were executed after the middle of the 15th century.

About 1400 the most prominent name is Lippo Dalmasio, called, from the subjects to which he almost confined himself, Lippo delle Madonne; some of his works remain, and Malvasia relates, with reference to one in the church of S. Procolo, that he heard Guido extol its purity and grandeur of expression, and assert that, notwithstanding the subsequent advancement of the art, no modern painter could infuse so holy a feeling into similar subjects. In this early epoch of

the school the predilection for the style of the Greek paintings, the common prototypes of Italian art, seems to have been more decided, and to have lasted longer than any other. It may be here observed that the modes of representation to which the Byzantine painters and their Italian followers adhered were in many cases consecrated by tradition, but independently of this the works themselves, rude as they were, often exhibited a solemnity of treatment which may in some degree account for the veneration in which they were held. The Florentines who visited Bologna and painted there left no permanent impression; a native artist, Marco Zoppo, who studied at Padua (where he was the rival of Mantegna) and afterwards at Venice, introduced the arrangement of the Venetian altar-pieces in some works subsequently done by him in Bologna; but the early simplicity or severity was preferred perhaps as fitter for religious subjects, and was rather confirmed than discarded by the greatest painter of the first epoch, Francesco Francia. This artist, who was contemporary with Raffaele, and survived him some years, according to Malvasia, was celebrated as a goldsmith and engraver of medals before he betook himself to the pencil at a comparatively advanced age. Vasari says that he was born in 1450, and that his first picture was dated 1490; but he had probably attained some celebrity before then, as in that year he was employed to paint the altar-piece of the Bentivogli chapel, and on other works of importance—though on the altar-piece just mentioned he is said by Lanzi to have signed Franciscus Franci, Aurifex, thus implying that he still regarded himself as much a goldsmith as a painter. Francia is celebrated as a painter who succeeded beyond most others in giving an expression of sanctity and purity to his Madonnas, and a letter of Raffaele's is extant in which this merit is particularly alluded to. Francia, who, in that middle style which the Italians have called *antico-moderno*, ranks with Perugino and Bellini, should, like them, have preceded the highest development of the art in a Raffaele or a Titian; but it is precisely in this highest corresponding point that the Bolognese school is wanting, and the eulogists of Francia have in vain endeavoured to exalt him to a level with the painters of the first rank with whom he happens nearly to coincide in date. Vasari relates that when the St. Cecilia of Raffaele made its appearance in Bologna, according to him in 1518, Francia, to whose care it had been consigned by the great painter himself, was so amazed at its vast superiority to his own efforts that he soon after died of mortification. Francia, it has recently been proved (Calvi, 'Memorie della Vita e delle Opere di Francisco Raibolini, detto il Francia') did in fact die in the beginning of that year, but Vasari's story has received no other confirmation, and its accuracy may well be doubted: he was in his 68th year at the time of his death. The school of Francia presents no distinguished names. The summit of the art had been already reached elsewhere, and his followers, who were inferior to him, were eclipsed by the disciples of Raffaele.

These introduced a more or less servile imitation of the style of their great model into Bologna; the best were Ramenghi called Bagnacavallo, and Innocenza da Imola. It is in the account of Bagnacavallo (which includes a notice of Innocenza, Aspertini, and Girolamo da Cotignola) that Vasari speaks so contemptuously of the Bolognese school. Bagnacavallo was however occasionally original, and some of his productions were considered worthy of the particular attention and study of succeeding masters. Three distinguished names precede the epoch of the Caracci: Primaticcio, Niccolò dell' Abate, and Pellegrino Tibaldi. Niccolò dell' Abate belongs strictly to the school of Modena, but he is associated with the Bolognese painters by some works at Bologna, by his joint labours with Primaticcio at Fontainebleau, and by the extravagant compliment paid to him in a sonnet by Agostino Caracci, in which he is said to unite all the excellences of all the great masters. Primaticcio and Tibaldi began their studies, though at very different times, under Bagnacavallo; the first, who was the elder by many years, assisted Giulio Romano at Mantua, and under his direction acquired a facility and a classic taste which he afterwards displayed in a series of designs for the ceilings of Fontainebleau, where he was employed by Francis I. and his successors. The frescoes painted from these designs, and which are now no longer in existence, were chiefly executed by Niccolò dell' Abate. Pellegrino Tibaldi soon left Ramenghi for Rome and Michael Angelo, to whose style he devoted himself; his successful imitation of the great Florentine master, whose powerful design he sometimes blended with the excellences of other schools, places him in a relation to his prototype similar to that which Bagnacavallo holds to Raffaele, and the Caracci honoured him with the appellation of "the Reformed Michael Angelo." Tibaldi was employed in Milan, and afterwards in Spain, and thus the three greatest masters of this intermediate period were absent from Bologna a great part of their lives.

The name of Prospero Fontana stands at the head of those who, living from the earlier to the latter part of the 16th century, and inheriting but little of the genius of the great masters, survived their own slender reputation to witness the rising fame of the Caracci. In the same class may be mentioned Passerotti, as the latest Bolognese painter alluded to by Vasari. The others may be passed over, with the exception of Denis Calvart, a native of Antwerp, who, after settling in Bologna, where he opened a school, not only had the honour of partly instructing Guido, Domenichino, and other celebrated Bolognese painters, but also of introducing that elevated style of landscape-

painting which afterwards added a new lustre to the school in the hands of the Caracci, Domenichino, Grimaldi, and others.

Thus the imitation of the two great Florentine and Roman masters lasted with no other change than that of increasing mannerism or insipidity, till beyond the middle of the 16th century, about which time the followers of the elder Zuccaro in Rome and those of Bronzino in Florence may be ranked with the Fontanas and the Passerottis of Bologna. The characteristic excellence of the Venetian school had been occasionally blended with the other styles, but in general the influence of each was separate and exclusive: meanwhile, owing to the ascendancy of the two first, the imitation of Correggio can hardly be said to have extended uninterruptedly beyond his own date, since Parmigiano, who indeed rather holds the rank of an original master, survived him but a very few years. Baroccio may therefore be considered to have led the way, about 1565, not only in including Correggio among the great models proposed for imitation, but even in preferring him to the rest. The example thus set to the Roman school was followed soon after by Cigoli in Florence, namely about 1580, a period which immediately precedes the dawning influence and fame of the Caracci. They too, from whatever cause, partook of the new admiration, and in their attempt to unite the excellences of the different schools, it was natural that a style, which had been hitherto in a great measure overlooked, should form a chief element of that eclectic perfection which was proposed as the object of attainment. Accordingly, the imitation of Correggio preponderates in the first works of these masters; and Annibale Caracci's letters from Parma prove that, like many other painters of the day, he considered the excellence of Correggio as a new discovery.

Lodovico Caracci, who had studied in Venice, Florence, and Parma, conceived the plan of introducing a new style, according to his biographers, when alone and unassisted, and it is said that he persuaded his younger cousins Agostino and Annibale to devote themselves to painting in order to aid him in effecting his purpose. He sent them, after well-grounded elementary studies, to Parma and Venice, from the latter of which schools it may be observed the Bolognese painters seem to have borrowed least. The first work of importance done after their return to Bologna was a series of compositions, representing the story of Jason, in an apartment of the Palazzo Fava: Lodovico himself assisted, but the greater part was the work of Annibale. The severe criticisms and opposition which this performance excited induced the Caracci to strengthen their party, and the famous school was opened which shortly attracted most of the rising painters who were studying with Denis Calvart, Cesi, and Fontana:—ample details as to the mode of study in the school of the Caracci may be found in Malvasia. The fame of these masters was soon after firmly established by their works; and Agostino, as an engraver as well as a painter, contributed to spread and sustain their name: but the enmity of the abettors of the old style was not completely silenced till the frescoes in the Palazzo Magnani were executed. Denis Calvart was the last to fall in with the general approbation; and it appears from Malvasia that his chief objection to the new mode of study was the constant reference to nature which was now deemed indispensable: from this objection the previous state of the schools and the manner of the painters of Bologna may be inferred.

Annibale Caracci repaired to Rome about or shortly before 1600, and painted in various churches; but his great work, the monument of his powers, and the specimen of the school most frequently quoted, although not perhaps the most characteristic, is the series of frescoes in the Farnese palace. In this work Agostino among others assisted: the Cephalus and the Galatea, according to Bellori, were painted entirely by him. The admirers of the antique and of the Roman school prefer this work even to Lodovico's performances in Bologna: Poussin and other painters, who visited Rome early in the 17th century, gave it the highest praise.

The followers of Lodovico at Bologna were, however, true to the founder of the school: posterity seems to have confirmed the opinion, and to have decided that this great painter, with less academic power than Annibale, is more original in style. Sir Joshua Reynolds thus speaks of Lodovico Caracci: "His unaffected breadth of light and shadow, the simplicity of his colouring, which, holding its proper rank, does not draw aside the least part of the attention from the subject, and the solemn effect of that twilight which seems diffused over his pictures, appear to me to correspond with grave and dignified subjects better than the more artificial brilliancy of sunshine which enlightens the pictures of Titian." (Discourse II.)

The principles and practice of the Caracci and their scholars superseded for a time every other style in Italy; yet it may be remarked that the efforts of Lodovico can hardly be considered so spontaneous and independent as the historians of art have commonly asserted. It has been already shown that a new impulse had manifested itself in the Roman and Florentine schools, even previously to the revolution which the Caracci effected; and whatever may have been the origin of that impulse, the sudden rise of various and powerful talents in Bologna may be considered a symptom rather than the cause of general improvement.

Among the numerous scholars of the Caracci, Domenichino holds the first rank; but the merit of this painter was long unnoticed in Rome, where he resided some time, owing in some degree to the

intrigues of his rivals. Poussin had the honour of bringing some of his best works into notice, and declared him to be, in his opinion, the greatest painter after Raffaele. By some modern critics, too, he has been preferred to the Caracci themselves: his chief excellence, and that in which he approaches Raffaele, is his expression. The graceful Albani, who left the school of Calvart for that of the Caracci, perhaps like Domenichino imbibed his taste in landscape from the Fleming: he communicated it to Francesco and Giovanni Battista Mola, who often suffered it to predominate in their own historical works, and who occasionally painted the landscape backgrounds to the figures of Albani: these consisted frequently of females and children in subjects connected with poetry or allegory, and he excelled in them perhaps more than in sacred subjects. The more brilliant talents of Guido excited the jealousy of the Caracci from the beginning. Lodovico encouraged Guercino as a rival to him, and Domenichino was put forward, it is said, for no other reason, by Annibale in Rome. The light and silvery tone which is observable in some of Guido's best works is said to have been owing to an accidental expression of Annibale Caracci, who at a time when the dark style of Caravaggio excited general attention, and was imitated among others by Guido himself, remarked that the opposite treatment, with appropriate subjects, would perhaps be still more attractive. Caravaggio, who was born in the Milanese, and painted in Rome, Naples, and elsewhere, cannot be placed in the Bolognese school, which however he greatly influenced: he belongs to the successful innovators who, at the close of the 16th century, sought to oppose literal and unselected nature to the insipid imitation of the purer styles, and may be considered the chief representative of a class of painters called by the Italians the *Naturalisti* and the *Tenebrosi*. Among the painters of the Bolognese school, Guercino, born at Cento, seems to have been most smitten with the vigorous effects of Caravaggio, although in his latest practice he acknowledged the charms of Guido's style, by attempting to unite it, perhaps with little success, to his own. His dark pictures are generally his best, and he sometimes united the higher qualities of expression and of form with the magic of his relief. Both Caravaggio and Guercino studied in Venice, and the former particularly aimed at the style of Giorgione; yet their works, however admirable, present but few traces of Venetian principles, and this is to be accounted for by the spirit of innovation which manifested itself in every branch of the art, and which took the opposite of the vices of the day. The negative and somewhat heavy colour of the two masters alluded to was opposed to a florid and weak imitation of the colourists, the excesses of which are ridiculed by Boschini in his 'Carta del Navegar Pittresco.'

Lanfranco, born at Parma, was another distinguished scholar of the Caracci, and assisted Annibale in the Farnese palace in Rome: his own great work, the cupola of St. Andrea della Valle in the same city, is the best specimen of his powers, and it is here that as a machinist (the term applied by the Italians to painters of large compositions on ceilings and in galleries) he aimed at the grandeur of manner and boldness of foreshortening which he had long studied in the works of Correggio at Parma.

Of the remaining disciples of the Caracci it may be sufficient to mention the names of Tiarini, Lionello Spada, and Cavedone. All the more noted scholars before mentioned had numerous followers, and perhaps none more than Guido. In these the manner of the respective masters naturally degenerated, and no new talent arose. The taste in landscape which the Caracci introduced or improved was inherited and almost exclusively practised by Giovanni Battista Viola, the Grimaldi, and others: the most perfect specimens of this branch of art, as practised in the school, are however to be sought in the works of Domenichino and Annibale Caracci.

About the year 1700 the greatest name was Carlo Cignani, a painter of considerable reputation in his day, and who so far revived the principles of the school that he professed to unite the anatomical science of Annibale Caracci with the more attractive qualities of Correggio. Under his auspices the Clementine Academy of Bologna was instituted, to preserve as much as possible the acknowledged principles of the art, and to point out the best models for imitation. But while the impulse which the Caracci and their scholars had communicated to the school was gradually exhausting itself, a pernicious and in many respects opposite tendency had been gaining ground. The specious facility and consequent popularity of the machinists, who imitated Vasari in Florence and the Zuccari and Arpino in Rome, had been with difficulty opposed by the united efforts of the Caracci, and appear to have been the chief causes of the neglect of Domenichino. This empty facility, no longer contrasted with such distinguished talents, was naturally considered the highest proof of ability, and by degrees almost extinguished the taste for well-studied imitation. A Bolognese writer and painter, Zanotti, who was long professor of the Clementine Academy, was one of the first to raise his voice against this destructive mannerism, and to recommend a more frequent reference to nature. He has been considered to have led the way to opinions far more decided than his own as to the necessity of returning to the first principles of imitation, and indeed to the methods of the earliest masters. These notions have been openly expressed in Germany, where the writers on art, allowing for some exaggeration in their views, have had the merit of directing the attention of the world of taste to the simple but impressive productions of the older Italian painters,

from whom Raffaele caught the feeling which aided him in his study of nature; and they have been, to a certain extent, adopted by the band of young painters in this country who assumed the designation of Pre-Raphaelite Brethren.

To recapitulate, the school of the Caracci has been often described as merely imitative, but perhaps this has arisen rather from the well-known and professed object of its institutors and followers than from a particular evidence of that object in their productions. If a certain resemblance of manner, whatever it be derived from, characterise the masters, it may be admitted that no school presents so much variety as is to be met with in the works of their disciples. This, it must be confessed, cannot be said of the followers of Michael Angelo and Raffaele. The example of an eclectic style may thus lead to a more original style, whereas the example of an original style, if it cannot be surpassed, can only end in a weaker copy. Yet assuming that the Caracci were as independent of the spirit of their age and as free to choose their path as their biographers would lead us to suppose, had they endeavoured to follow up the feeling of Francia (not to return to Lippo Dalmasio or to Giotto), they might have succeeded in connecting the highest effort of the school with that earlier, national, or local style, which, as we have seen, was nipped in its growth before it was fully developed, partly perhaps because Francia devoted himself so late in life to the art, and thus still adhered to the incomplete and, as it were, preparatory mode of imitation when the perfect one had already been introduced. The merit of this painter, as one of the characteristic Italian masters, should not however be forgotten, and his style is not the less interesting from being connected with that original school of Umbria, distinct from the Florentine, which was remarkable for purity of expression, and which had so much influence on the education and genius of Raffaele.

We will only add that our National Gallery contains the following works of painters of the Bolognese school, taken in their chronological order:—Of the 15th century, there are by Marco Zoppo (who painted from 1471 to 1498) 'St. Dominic as the Institutor of the Rosary' (a good example of the mystical tendency which Rio terms the distinctive feature of the early school of Bologna); and by Francia (1450-1518), 'The Virgin with the Infant Christ and St. Anne enthroned, surrounded by Saints,' and a 'Pieta' (or 'Virgin and two Angels weeping over the dead body of Christ'), which served as the lunette to the former, the two pictures together forming the altar-piece of the Buonvisi chapel in the church of San Fridiano at Lucca. Of the 16th century, there are by Lodovico Caracci (1555-1619) an 'Entombment of Christ,' and 'Susannah and the Two Elders;' by Agostino Caracci (1559-1602) two cartoons, 'Cephalus and Aurora,' and 'Galatea;' and by Annibale Caracci, no fewer than eight paintings, 'Christ appearing to Peter after his Resurrection,' 'St. John in the Wilderness,' 'The Temptation of St. Anthony in the Desert,' 'Silenus gathering Grapes,' 'Pan teaching Apollo to play on the Pipes,' 'Erminia takes refuge with the Shepherds,' and two landscapes. Of the 17th century, by Domenichino (1581-1641), 'The Stoning of St. Stephen,' 'St. Jerome and the Angel,' and two landscapes; by Guido (1575-1642), 'Lot and his Daughters leaving Sodom,' 'The youthful Christ embracing St. Peter,' 'Ecce Homo,' 'The Magdalen,' 'The Coronation of the Virgin,' 'Susannah and the Elders,' 'St. Jerome,' 'Perseus and Andromeda,' 'Venus attired by the Hours;' by Guercino (1592-1666), 'Angels weeping over the Dead Body of Christ;' and by Pietro Francesco Mola (1612-1668), 'St. John Preaching in the Wilderness,' and 'The Repose of the Holy Family.' (Ample descriptions of these pictures will be found in the excellent 'Catalogue of the National Gallery,' by R. N. Wornum.)

BOLOGNIAN PHOSPHORUS. [BARIUM; *Baryta, Sulphate of.*]

BOLORETINE ($C_{40}H_{32}O_6$?) is the name of one of four resinous compounds found in the peat of Denmark, on the remains of pine trees. It is a fusible compound, but not crystalline.

BOLSOVER STONE. The yellow limestone of Bolsover in Derbyshire has been used in the construction of the new Houses of Parliament. It was selected for its durability, strength, fitness for ornamental work, and colour. It is a combination of carbonate of magnesia with carbonate of lime, in small granular crystals, without the slightest trace of organisation, flinty nodules, or other blemishes. It was subjected to various and severe mechanical pressures, chemical reagents, &c., and sustained them with credit; but experience has shown that it cannot withstand the atmosphere of London any more than the Bath and Portland oolites.

BOLTHEAD, a chemical vessel, usually of green glass, and of a globular form, with a narrow neck. It is chiefly employed in the processes of ebullition and sublimation.

BOMB, the original name of what is now called a shell, is a hollow globe of iron, which, when charged with a certain quantity of gunpowder, is projected from a mortar or howitzer, generally at a considerable angle with the horizon; in order that, by the momentum acquired in its descent, it may crush through the roof, and, by exploding, destroy any building on which it may fall. The name is thought to have been given as an expression of the sound produced either in the explosion, or at its discharge from the piece of artillery employed to project it.

It is said by Strada, in his account of the wars in the Low Countries, that bombs were employed for the first time in 1588 by Ernest, the father of Charles, Count of Mansfeldt, at the siege of Wachtendonk, a

town near Gelders. He adds that they were invented, a few days before that siege commenced, by an inhabitant of Venlo; and it is stated that the people of this city, wishing to exhibit the invention in presence of the Duke of Cleves, discharged a bomb, which falling on one of the houses set fire to it, and, the flames spreading, three-fourths of the town were destroyed before they could be extinguished. (Père Daniel, 'Histoire de la Milice Française,' liv. vii. chap. 6.) But Grose relates that a French translation, made in 1555, of a work by Valturinus, was accompanied by a print representing a cannon just fired, with a ball in the air and another on the ground, both of which were burning at the vent. A title to the print denoted that this was a contrivance for firing a ball filled with powder; and as the first edition of Valturinus is dated 1472, it appears from thence that bombs must have been invented about the middle of the 15th century. Blondel, however, in his treatise entitled 'L'Art de Jetter les Bombes,' remarks that bombs were used by the French for the first time in 1634, at the siege of La Mothe, under the direction of one Malthus, an English engineer, who was invited from Holland by Louis XIII., and was afterwards killed at the siege of Gravelines.

In 1688, there was cast in France an enormous bomb, which is said to have been in the form of an egg, and to have been capable of containing 7000 or 8000 pounds of powder; it was nine feet long and five feet in diameter, and the iron was six inches thick. The bomb was to have been discharged against the Algerines, and the ship in which it was embarked was to have been blown up with it. It was not however employed, probably in consequence of an opinion that it would not have had the intended effect, and no attempt has since been made to project such an immense mass of metal. While the Citadel of Antwerp was besieged by the French army in 1832, shells twenty-four inches in diameter were thrown from the largest mortar which has been employed in modern warfare; the shell or bomb was capable of containing ninety-nine pounds of powder, and when charged weighed 1015 pounds.

The word bomb being now nearly superseded, except as a component in those which express the subjects of the three following articles, and in the term bombardier, which is applied to the soldier whose duty it is to serve the ordnance from which shells are projected, the description of this missile will with most propriety be introduced under the words which denote the different species at present in use: as **CARCASS**, **CASE-SHOT**, **GRENADE**, and **SHELL**.

BOMB-PROOF. This name is given to a military magazine, or other building, when its roof has sufficient thickness to resist the shock of shells from mortars falling on it. Under the word **BLINDAGE** is given the construction of such buildings of timber as are intended to secure troops or artillery from the effects of what is called vertical fire; and under the word **CASEMATE** is shown that of the vaults which are formed in the masses of ramparts to serve for the like purposes. A bomb-proof however is generally understood to signify an isolated building, rectangular on the plan, formed of brick or stone, and covered with a vaulted roof of the same material. The intrados, or interior line, in a vertical and transverse section of the vault, is sometimes a semicircle, but now more generally a parabola; and the exterior surface of the roof is formed by two inclined planes meeting in a ridge which is parallel to the sides of the building and over the middle of its breadth. By this construction, the greatest thickness is given to the crown, or centre part, where a falling shot or shell would be most injurious to the stability of the arch of the vault. It is intended to serve as a powder- or store-magazine, an hospital, or to cover a battery of guns or mortars; and when constructed in a fortress for the first of these purposes, it should not only be isolated, but should also be situated in some spot at a distance from the fronts likely to be attacked, and secured as much as possible against accidents.

As the details of the construction and uses of such buildings are given under **MAGAZINE**, it is only necessary to observe here, that the span, or interior width of a bomb-proof vault, is usually about eighteen feet, and the thickness of the arch three feet at the hances or sides. But the extrados, or exterior of the vault, should be covered with a bed of earth about five feet deep, to deaden the concussion produced by the shells which may strike it; this earth should be renewed as fast as it is blown away by the explosions, to prevent the shell from falling on the naked vault; for, as each shell would tear off the masonry to the depth of two or three inches, it is evident that the building would be totally destroyed after a few successive shocks.

BOMB-VESSEL. What was, till recently, called a "bomb-vessel," was a ship of about 350 tons burthen, intended to co-operate with a fleet or squadron, in throwing shells from mortars of large dimensions, such shells being 13-inch or 10-inch: they were in addition armed with light carronades. A greater beam or breadth was generally given to these vessels, and their heavy mortars worked on traversing platforms so as to command a wide horizontal range. Great changes, however, are taking place in this class of vessel, and in this arm of naval service—mainly due to the invention of Sir William Armstrong. These will be described under the word **MORTAR-BOAT**.

BOMBARDIER, a non-commissioned officer of the royal regiment of artillery, whose duty it used to be to load shells, grenades, &c.; to make and fix the fuses, and who was particularly appointed to the service of mortars and howitzers. At present the term is merely applied to the non-commissioned officer who holds the same rank as a

lance corporal in the line. There are a certain number of bombardiers to each company of artillery.

BOMBARDMENT. This is the action of throwing shells, carcasses, and shot into an enemy's town in order to destroy the buildings, and chiefly the military magazines; for which purpose mortar, howitzer, and gun-batteries are constructed in convenient situations, generally opposite to the most densely inhabited quarters. If the town is a seaport, bomb-vessels also are moored along the shore, and the firing is kept up simultaneously on the land and sea-sides of the place.

When an army invests a fortress, whether it proceed against it by the operations of a regular siege, or simply keep it in a state of blockade, a bombardment is one of the means resorted to in order to accelerate the surrender, by rendering its occupation dangerous to the citizens, and ruining the buildings in which the ammunition is secured, or in which the garrison while not on duty find repose.

Among civilised nations it has become a principle to spare as much as possible the lives and property of individuals who are not actually engaged in the military service of the state against which an army is employed; since, besides the cruelty of acting otherwise, the object in view, which is the final termination of hostilities, is not in the smallest degree advanced. The practice of besieging fortresses is now so far reduced to a regular process that the time of their surrender may be confidently anticipated by so employing the artillery that, while it effectually dismounts that of the enemy, and lays the rampart in ruins in the ditch, it scarcely produces the smallest injury to any but the defenders of the works: hence the simple bombardment of towns occurs so much less frequently now than in former times, and no circumstance is considered as a justification of the measure except the absolute inability to reduce a place by other means.

When a town is, from the fate of war, about to become subject to a bombardment, the garrison should endeavour to retard the calamity by the erection of advanced works about the place, or by keeping troops in the suburbs and neighbouring villages as long as possible. By this measure provisions, materials, and even workmen will be obtained in abundance for the service of the defenders; the inhabitants of the fortress also, finding that the garrison is not shut up within the walls, will be inspired with confidence in its protecting power, and thus induced to suffer less unwillingly the privations and dangers to which they must inevitably become exposed. The enemy moreover will be compelled either to abstain from constructing a line of *counter-vallation*, as it is called, to prevent the sorties of the garrison; or, if such is attempted, the line must be so extensive as to require a long time for its formation, and the works constituting it must be so far asunder as to render it impossible to watch the avenues of the place with sufficient care to prevent all communication between the town and country. The power of acting offensively may thus be not wholly taken away from the garrison, and the enemy may be kept at such a distance as to lessen materially the effect of the bombardment. What has been said must not be understood to imply that any village, suburb, or building, which by falling into the power of the enemy might facilitate his operations, is not to be destroyed before he can get possession of it; but it is evident that the object in view, which is the preservation of the place, and of its docks and arsenals, if it be a naval station, will be most effectually obtained by keeping the enemy as long as possible at a distance from them beyond the range of his artillery.

The garrison must of course employ a fire of the heaviest artillery to destroy the enemy's batteries as soon as they are formed. The casemates and blindages in the town should be repaired and multiplied; and the ammunition should be kept in small quantities in each, in order to avoid the loss and damage which would be occasioned by the explosion of a large, and full magazine; for which reason also, it should be disposed in the quarters least subject to the fire of the enemy. Wells and cisterns should be protected by shell-proof blindages, the fire-engines carefully secured, and companies of men formed whose duty should be to proceed immediately with the engines to any spot where a fire may have broken out. The utmost intrepidity is required in men employed on this service, which is rendered particularly dangerous, because the enemy always continues to direct his fire towards any spot at which flames are seen to rise, in order to prevent if possible the defenders from extinguishing them. When red-hot shot are thrown into a town, men should always be appointed to seek them and, by pincers or otherwise, remove them to places where they can do no harm.

A strict police is to be maintained, and every precaution used to prevent conspiracies among the citizens for delivering up the place. For now, since the loss of a town does not, as in ancient warfare, entail upon the inhabitants the loss of life or liberty, it is easy to conceive that their interest in their property must unavoidably lead them to desire the cessation of the bombardment, though at the price of the transfer of the town to the enemies of their country; and it must be expected that they will use every means in their power, whether of persuasion or force, to compel the commander to surrender.

The most celebrated bombardments mentioned in history are those of Gibraltar, Copenhagen, Algiers, and Sebastopol. The first of these places was invested on the land-side by a Spanish army, which was afterwards united to that of France, and on the sea-side by the com-

bined fleets of the two nations. The investment took place in 1779, but no remarkable actions occurred till 1782. The town was twice distressed for want of provisions; the highest works of the fortress, though 1340 feet above the level of the enemy's batteries, were destroyed by shells from the latter several times; attempts were also made by the besiegers both to fire the ships in the harbour and to annoy the British army by gun-boats.

On the other hand, the garrison was employed in strengthening the old fortifications and adding new batteries, and in making occasional sorties against the Spanish lines. In the last-mentioned year, however, the besiegers converted some of their large ships into floating batteries, which, on September 13, commenced a tremendous fire on the town, while the land-batteries cannonaded the works in flank and rear; the garrison, in return, paying little attention to these, poured on the ships a fire of carcasses, shells, and red-hot balls. This work of destruction continued on both sides till about seven or eight P.M., when it nearly ceased. The utmost confusion and distress by this time prevailed in the fleet of the besiegers; several of their largest ships had caught fire, and two of them blew up with tremendous explosion. The general peace, which was made in the beginning of the next year, put an end to this memorable siege after it had been carried on nearly four years.

The bombardment of Copenhagen took place in 1807, and was effected by a British army under Lord Cathcart, which closely invested the city on the land side, while the fleet under Admiral Gambier blockaded the harbour. The fire from the land-batteries and bomb-vessels opened on the evening of September 2, and continued till the night of September 4, when a capitulation took place. In this bombardment the rockets invented by Sir William Congreve were used for the first time; and it is said that the cathedral, with above 300 houses, was destroyed by the shot and shells which were thrown into the town. Another action of this nature occurred in 1816, when the united fleets of England and Holland, consisting of fifteen ships of war, besides gun-boats, under the command of Lord Exmouth, bombarded Algiers. The firing continued during twelve hours, in which time all the enemy's ships in the harbour were destroyed and great part of the town.

The last bombardment was that of Sebastopol, which can perhaps hardly be strictly termed a bombardment, as though a good deal of the fire was directed on the town, the principal part was on the works. The following is a return of the shot and shell expended by the English alone in the six successive bombardments:—In the first bombardment, commencing October 17th, 1854, 72 siege guns were employed, and they fired 21,881 rounds. In the second, commencing April 9th, 123 guns fired 30,633 rounds. In the third, commencing June 6th, 155 guns fired 32,883 rounds. In the fourth, commencing June 17th, 166 guns fired 22,684 rounds. In the fifth, commencing August 17th, 196 guns fired 26,270 rounds. And in the sixth and final bombardment of the 8th of September, 207 guns and mortars fired 28,476 rounds. In addition to this, 88,640 rounds were fired at different times, between the regular bombardments, and 405 rounds of *carcasses* and *light-balls*, giving a total of 251,872 rounds of shot and shell fired during the whole siege, or about 6000 rounds a week. The expenditure of ammunition by the fleet was also enormous, as the *Agamemnon* alone, in the attack of the 17th of August, in about four hours fired more than 3000 rounds.

BOMBAZINE (from the Greek *βόμβυξ*, which signifies both the silkworm and the silk produced by it) is a woven fabric in which the warp is formed of silk, and the weft, or shoot, of worsted. The worsted is thrown on the right side, which has a twill upon it. The manufacture originated in Norwich, among the Dutch who were settled in that city, about 1575. Bombazines were formerly made of various colours, but owing to changes of fashion they are now manufactured almost entirely in black, and are now only used, and that to a limited extent, as mourning.

BOMBIC ACID. The silkworm, especially in the chrysalis state, contains an acid liquor, and hence the name of bombic acid. It was discovered from the circumstance of blue paper, which had been accidentally laid near these insects while changing to the state of chrysalis, being found covered with red spots, as if drops of acid had been spilled upon it.

When the insect is subjected to pressure it also yields a liquor from which alcohol precipitates mucilage, oil, and glutinous matter, and leaves bombic acid in solution; by evaporating this there is obtained an acid pungent fluid of an amber colour, which reddens vegetable blue colours, and forms salts with the alkalies, earths, and metallic oxides, which have been called *bombiates*.

This acid product has not been examined of late years, and is scarcely noticed by modern authors. Neither its nature nor that of its salts is accurately known; and it is not even certain that it is a peculiar acid. It is probable that a re-examination would show that it is similar to the formic acid, or acid of ants.

BONA FIDES and **BONÂ FIDE** is an expression often used in the conversation of common life. It is also often in the mouths of lawyers, and it occurs in acts of parliament, where (in some cases at least) it means that the act referred to must not be done to evade the law, or in fraud of the law, as we sometimes express it, following the Roman phraseology, in *fraudem legis*. It appears to be used pursuant to the meaning of the words, in the room of good faith, which implies the absence of all

fraud or deceit. *Bona Fides* is therefore opposed to fraud, and is a necessary ingredient in contracts, and in many acts which do not belong to contracts. How much fraud may be legally used, or what is the meaning of *Bona Fides* in any particular case, will depend on the facts. Many things are not legal frauds, and many things are legally done *Bona Fide*, which the common notions of fair dealing condemn.

The phrase *Bona Fides* originated with the Romans, and it is opposed to *Mala Fides*, or *Dolus*. The notion of equity (*æquitas*), equality, fair dealing, equal dealing, is another form of expressing *Bona Fides*. He who possessed the property of another *bona fide*, might, so far as the general rules of law permitted, acquire the ownership of such property by use (*usucapio*). In this case *bona fides* consisted in believing that his possession originated in a good title, or, as Gaius (ii. 48) expresses it, when the possessor believed that he who transferred the thing to him was the owner.

The Romans classed under the head of *bonæ fidei* obligations a great variety of contracts, and also of legal acts, as buying, selling, *mandatum*, guardianship, &c. Actions founded on these obligations were called *bonæ fidei actiones*, a name which arose from the formula "*ex bonâ fide*," inserted in the *Intentio*, or that part of the *Prætor's* formula which had reference to the plaintiff's claim, and empowered the *judex* to decide according to the equity of the case, *ex fide bonâ*. Thus actions founded on contract, or on acts which bore an analogy to contract, were distributed into *stricti juris actiones* and *bonæ fidei actiones*; or actions in which the inquiry was about the strict legal rights of the parties, and actions in which the general principles of fair dealing were to be taken into the account. The object which was attained by the latter bears an analogy to the relief which may be sometimes obtained in a court of equity in England, when there is none to be had in a court of law.

BONA NOTABILIA. [EXECUTORS.] The doctrine of *Bona Notabilia* has been abolished with the Courts whose jurisdiction depended on it, there being now but one Court of Probate for all England. [PROBATE.]

BOND. A bond or obligation in law, is a deed by which he who makes it, called the *obligor*, binds himself to another called the *obligee*, to pay a sum of money, or to do, or not to do, any other act. It is, in fact, a species of covenant. [COVENANT.]

Bonds for the payment of money are the most common. They are employed instead of promises by word, or by unsealed writing, for the following reasons. First, a bond (like every covenant) to pay a sum of money may be enforced against the obligor, although no legal motive or consideration existed for making it (which is not the case with a verbal promise), for a deed cannot be set aside by the maker of it, though gratuitous. Hence, voluntary engagements which are intended to be binding in law should be made by bond or covenant. Secondly, though the sum of money which a person is to oblige himself to pay is a debt already existing, or though any legal consideration for its payment exists, so that a promise by word or by unsealed writing to pay it would be binding in law, yet a bond is a better security; for if the debtor dies before the debt, though due, is paid, the creditor being, by virtue of the bond, among those who are called creditors by *specialty*, will be entitled to be satisfied out of the personal and real assets [ASSETS] of the deceased, before creditors by *simple contract* (among whom, if he had only the verbal promise or promissory note of his debtor, he would be reckoned) receive any part of the debts due to them. In order, however, that a bond debt may be thus payable out of the real assets of the debtor (his lands of which he died seized) before his simple contract debts, the debtor must, by the bond, have expressly bound himself and his heirs to pay the debt.

Another advantage which a bond has over a bill of exchange or promissory note is that an action may be brought upon it at any time within twenty years after it is due; whereas a simple contract debt is barred by the statute of limitations after six years. [LIMITATIONS.]

A bond, though thus a better security in many respects than a promissory note or bill of exchange, is inferior to them in one particular; for it cannot be assigned in law, so as to give the assignee the right of suing, in his own name, the obligor for the debt. The courts of equity, however, support, as far as they can, assignments of bonds to purchasers, and acknowledge and enforce the right of such assignees to receive the bond debts out of the assets of the debtors; and the legal difficulty is got rid of by the assignor of the bonds giving the assignee a power of attorney to sue in his name.

A bond is so good a security for the payment of a sum of money, that it is often employed not only when a debt is to be established, but when a pecuniary penalty is to be provided. When a man is required to oblige himself to do or not to do any act, he often enters into a bond for payment of a certain sum of money, as a penalty in case he departs from his agreement. A bond of this kind, which is called a *penal bond*, is always prepared as follows: It is a simple bond for payment of the penal sum, no time or event being mentioned when that shall be due: but a condition is added for making the bond void, in case the obligor performs his duty; the nature of such duty being expressed in the condition. This may seem not to be the most accurate mode of securing a contingent penalty; but, construed by law, such a bond answers its purpose. For though, generally, when a bond for payment of a sum of money mentions no time of payment, an action may be brought upon it immediately; yet in this case the

penal sum is not considered to be due or recoverable till the condition annexed to the bond fails of effect by the obligor neglecting or departing from his duty. These penal bonds are further rendered equitable in their operation by the liberal construction which the law puts upon the conditions annexed to them; often holding that such conditions take effect, and that their terms have been sufficiently observed, when, according to a more rigid construction, the penalties would have been forfeited; and often restraining obligees from taking advantage of the failure of such conditions, when they ought not, in justice, to receive the penalties. Even when the obligee in a penal bond is allowed to recover the penalty, he cannot, generally, take any more of it than what is a reasonable compensation for the damage sustained by him; and the amount of such compensation will be ascertained by the verdict of a jury. (8 & 9 Will. III. c. 11.)

The obligor in a penal bond being thus protected, it may seem that equal relief should be given to the obligee, when the penalty is not, as usual, greater than the amount of damage sustained by him, but less. However, it is a general rule, that the obligee cannot recover upon his bond any pecuniary compensation beyond the penal sum expressly secured. But the Courts of Equity consider the condition of every penal bond to be evidence of an agreement on the part of the obligor to perform the duty whose performance is to relieve him from the penalty. Thus a condition for making a bond void in case the obligor does or does not do any act, shows, in contemplation of equity, an agreement by him to do or not to do such act; and this agreement will, in many cases, be enforced against him at the suit of the obligee, by a decree for specific performance of the agreement, or by an injunction against its breach; and thus, even where the penalty in a bond is insufficient, the obligee is not always without remedy.

The courts of Law do not consider that an implied covenant is created by the condition of a bond, so as to allow the obligee to bring an action upon it; but they, as well as those of equity, so far take the condition to be evidence of a contract upon which the bond is founded, as to hold the bond to be void, if the condition is unlawful. For though, as before said, a bond without consideration may be valid, yet a bond made for an unlawful consideration, or upon an unlawful contract, is void, like every other deed so circumstanced.

Penal bonds have entirely superseded bonds without condition, or *single bonds*; for even when a bond is intended to secure the payment of money, the constant practice is to make it in the form of a bond for payment of a penal sum, double the principal sum which is really to be paid, with a condition, making the bond defeasible upon the latter sum being duly paid with interest. The chief advantage of such a bond over a single bond formerly was, not that more money than was fairly due to the obligee could be recovered under it (for the stat. 4 & 5 Anne, c. 16, forbids that), but that full interest, up to the day on which the debt was satisfied, may be obtained, if within the penalty; whereas, under a single bond for payment of the principal and interest at a certain day, no interest beyond that day could be claimed, until this defect of the law was remedied by stat. 3 & 4 Will. IV., c. 42, s. 28.

A bond is sometimes made by or to several persons together. In such case, the bond may have different effects, according as it is prepared, as either a joint bond, a several bond, or a joint and several bond. This distinction applies equally to covenants, and is noticed under that title. [COVENANT.]

The several modes in which a bond may be discharged (when not actually satisfied) may also be learned by referring to the same title; where the principal rules relating to the discharge of covenants, which equally apply to bonds, are mentioned.

BONE-ASH (*Bone Earth, Animal Earth*). When bones are strongly heated in open vessels, the whole of the organic or animal matter is burnt off, and a white ash remains, to which the above names are applied. A glance at the following analysis of dried bones, given by Berzelius, will at once indicate the composition of this ash:—

	Human Bones.	Ox Bones.
Animal matter (Osséine)	33.30	33.30
Phosphate of lime, with a little fluo- ride of calcium	53.04	57.35
Carbonate of lime	11.30	3.85
Phosphate of magnesia	1.16	2.05
Soda, and a little chloride of sodium	1.20	3.45
	100.00	100.00

In addition to the inorganic constituents mentioned in this table, bone-ash contains sulphate of lime produced by the oxidation of sulphide of calcium, the sulphur of which is derived from the animal matter. The principal and only important constituent of the ash is the phosphate of lime, forming from 80 to 90 per cent. of well-calcined bones. It may be separated from most of the other ingredients, and rendered nearly pure, by digesting the ash in hydrochloric acid, filtering, precipitating with solution of ammonia, and well washing the precipitate. Its composition is (3CaO, PO₅).

Bone-ash is largely used in compounding artificial manures, as a source of phosphorus, by assayers for making cupels, and in a few other less important operations.

BONE-BLACK (*Ivory-black, Animal-black, Animal Charcoal*). This

substance is manufactured by heating bones in vessels so contrived as to prevent any access of atmospheric air. The bones having been freed from fatty and fleshy matter by long boiling, are heated in a large still or retort made of cast iron or Welsh bricks; it is usually two to three feet square, from fifteen to twenty feet high, and surrounded by a furnace of brick-work. The bones are introduced through an opening at the top, which may be closed by an iron plate; and a steady ignition is kept up for a proper time, convenient arrangements being made for conveying away the volatile products of decomposition. The carbonaceous residue is received through a double trap-door at the bottom of the furnace into cast-iron canisters, which are immediately closed and set aside, that the bone-black may cool. It is then sent into commerce, in a coarsely granulated condition. During the operation the bones lose an average weight of 50 per cent.; some of the matters driven off by the heat are, however, condensed and utilised. [BONE LIQUOR.]

Bone-black necessarily varies somewhat in its quantitative composition; but the following analysis is probably a near approximation to the average amount of its several constituents:—

	Parts.
Phosphate of lime	80.0
Carbonate of lime	5.0
Charcoal	14.0
Carbide or silicide of iron	1.0
Sulphide of calcium or iron	traces
	100.0

Nearly the whole of the inorganic ingredients may be removed by digesting the bone-black in hydrochloric acid, which dissolves them; the residue well washed with water is nearly pure carbon, and is known in commerce as purified animal charcoal.

Bone-black is chiefly used as a decolorising agent in various chemical and pharmaceutical processes; but more especially in the refining of sugar, for depriving the crude syrup of its colouring matter, which is thus better effected than by any other process. M. Bussy, who has paid much attention to this subject, has drawn up the following table, showing the power possessed by various kinds of charcoal of decolorising solutions of indigo and molasses. The indigo solution contained one-thousandth part of its weight of indigo; the molasses was mixed with twenty times its weight of water. The amount of charcoal employed in each experiment was one gramme (= 15.34 grains). The third and fourth columns contain numbers showing the relative decolorising values of the various charcoals, when compared with common bone-black.

KIND OF CHARCOAL EMPLOYED.	Indigo Solution decolorised.	Molasses Solution decolorised.	Comparative Power on Indigo.	Comparative Power on Molasses.
	grammes	grammes		
1. Bone black	32	9	1.00	1.00
2. Vegetable or animal oil charred with phosphate of lime	64	17	2.00	1.90
3. Bone black purified by washing with hydrochloric acid	60	15	1.87	1.60
4. No. 3 calcined with potash	1450	180	45.00	20.00
5. Calcined lamp-black	128	30	4.00	3.30
6. No. 5 calcined with potash	550	90	15.20	10.60
7. Charcoal from carbonate of soda decomposed by phosphorus	380	80	12.00	8.00
8. Charcoal of acetate of potash	180	40	5.60	4.40
9. Starch charred with carbonate of potash	340	80	10.60	8.80
10. Albumen charred with potash	1080	140	34.00	15.00
11. Gelatine charred with potash	1150	140	36.00	15.50
12. Blood charred with phosphate of lime	380	90	12.00	10.00
13. Blood charred with chalk	570	100	18.00	11.00
14. Blood charred with potash	1000	180	50.00	20.00

An attempt has been made to substitute bone-black by common wood-charcoal, artificially impregnated with alumina, phosphate of lime, &c., but without practical success. An excellent decolorising charcoal may also be made by calcining pitch, tar, resin, &c., with hydrate of lime, removing the latter with hydrochloric acid, washing, and drying at a hot-water temperature; but, unlike bone-black, this charcoal, when saturated with colouring matter, cannot have its decolorising power restored by re-ignition.

According to Dr. Stenhouse, decolorising charcoals act either by virtue of their porosity (*e.g.*, purified animal charcoal), by the mordants they contain (*e.g.*, the artificially prepared phosphate of lime or aluminised charcoal), or in both ways, like ordinary bone-black. The inorganic ingredients also fulfil another office; namely, that of separating the particles of charcoal from each other, and thus preventing them from agglutinating, which always takes place when the charcoal is heated alone.

Animal charcoal not only absorbs colouring matters, but to a certain

extent deprives infusions of most of the active medicinal herbs, &c., of their active principles, and even takes from solution certain metallic salts.

Ivory-dust, when calcined in the same manner as directed for bones, yields when finely ground a charcoal of a rich velvety-black colour, extensively used as a pigment. The article used largely by blacking manufacturers, and known as ivory-black, is merely finely ground bone-black.

BONE-LIQUOR. When bones are submitted to destructive distillation for the purpose of manufacturing bone-black, liquid products of most intensely offensive odour distil over. This distillate separates into two layers: one forming a heavy, black, tar-like fluid, which constitutes what is known as *bone-oil* (consisting of a complex mixture of hydrocarbons, organic bases, &c.); and another and lighter one, consisting chiefly of a solution of carbonate of ammonia in water. The latter is commonly known as *bone-liquor*, and is much employed for the manufacture of the salts of ammonia, especially the carbonate, sulphate, and hydrochlorate. [AMMONIA.]

BONES have long been extensively used as manure, especially on poor and dry sands and gravels. They have thus become a considerable article of commerce with Germany, Belgium, and Holland, in Europe, and with the chief parts of South America.

Experiments on bones as a manure were made long before their use was extensively adopted, and these, in general, were not attended with a very favourable result, in consequence of the bones not being broken into sufficiently small pieces, or being put upon the land in too fresh a state. But since mills have been erected to crush them to a small size, and the proper use of them has been ascertained, the advantage of this manure in distant and uncultivated spots, where the carriage of common stable or yard manure would have been too expensive, and where it could not be made for want of food for cattle, is incalculable. By means of bones, large tracts of barren sands and heaths have been converted into fertile fields.

The bruising or grinding of bones soon became a distinct business. They were broken into different sizes, accordingly called *inch bones*, *half-inch bones*, and *dust*. Most of the bones procured from London and the manufacturing towns have undergone the process of boiling, by which the oil and a great part of the gelatine which they contain have been extracted. The bones imported from South America have been burned, and are properly bone-ash, the mineral part alone remaining.

At first sight we should be led to imagine, that having lost much of the rich animal matter which they contained, they would be proportionably less effective in the soil. This however does not seem to be the case from the comparative experiments made with bones which have been subjected to either burning or boiling, and those which are quite fresh. All those who have used bones extensively report, that little difference can be observed between them; some even give the preference to those from which the glue has been extracted. But glue forms excellent manure. How is this to be explained? It appears, from the result of many experiments, that bones do not furnish much nourishment to the roots of plants until they have undergone a certain degree of decomposition. The fat and the gelatine, being intimately blended with the bony matter, and contained in cavities or cells, may remain a long time in the earth without decomposition. As a proof of this, it has been found that bones which had lain in the earth for many centuries, on spots where ancient battles were fought, afforded, on analysis, nearly as much gelatinous matter, by the abstraction of the earthy parts, as fresh bones would have done. Bones analysed by Fourcroy and Vauquelin were found to consist of—

	Parts.
Solid cartilage, gelatine, and oil	51
Phosphate of lime	37.7
Carbonate of lime	10
Phosphate of magnesia	1.3
	100.0

The more recent analyses of the bones of the sheep and ox by Berzelius and others are as follow:—

	Thomson.		Berzelius.
	Ileum of Sheep.	Ileum of Ox.	Bones of Ox.
Organic matter (combustible)	43.3	48.5	33.3
Phosphate of lime	50.6	45.2	55.45
Carbonate of lime	4.5	6.1	3.85
			Phosphate of Magnesia.
Magnesia	0.9	0.2	2.05
Soda salts	0.3	0.2	2.45
Potash	0.2	0.1	..
Fluoride of calcium	..	..	2.90
	99.8	100.3	100.00

It is obvious from these, that bones must vary greatly, according to their age and other circumstances.

It would seem, then, that the great effect of bones, as a manure, must depend on the phosphate of lime; and the effect of bone-ashes seems to strengthen this opinion. As to the boiled bones, the more the bone has undergone fermentation, the more soluble its gelatine will

be. In its fresh state it is only soluble in very warm water, and the oil repels moisture. This accounts for the seeming anomaly of the superiority of boiled bones; they have undergone a fermentation. The residue, although not deprived of all its animal matter, is much more porous, and will imbibe and retain moisture in its pores. The food of the plants is here ready prepared and dissolved, and kept in store without being in danger of being washed through a porous soil or evaporated by the heat. All parts of the bone contribute ultimately to the fertility of the soil. Its gelatinous and fatty parts, though a protection to the bone against the destructive action of air and rain-water, are themselves ultimately liable to decomposition, and yield by that process soluble products available for the food of plants. It is in this fact that the value of even fresh bones as manure lies. The explanation of the greater value of bones boiled and even burned, and of bones reduced to powder for manure, lies in the fact that this gelatinous and fatty envelope, though shortly becoming utilised itself, is in the mean time a hindrance to the action of those atmospheric solvents which would reduce the mineral part of the bone to a soluble condition.

It is ascertained that the effect of bones on the crop is much increased when they have been previously mixed in heaps with ashes, burnt clay, or light loam, or made into a compost with the dung of animals, and with vegetable substances. In this case, the fresh bones will evidently be much more advantageous than those which have been boiled; for the fermentation will extract and decompose the oil and a great part of the gelatine, which, mixed with the other ingredients of the compost, will much enrich them; while the bony residue will be in the same state as it would have been if the bones had come from the boiling-house. By comparing all the facts, we naturally come to the conclusion, that the most economical use of bones is to extract from them the oil and gelatine, which if not of sufficient value for the manufacture of glue or of ammonia, may be used as a supplementary food for pigs, in the form of a broth or pot liquor, which, mixed with meal, will greatly accelerate their growth or increase their fat. For this purpose the bones should be broken in the mill to a moderate size, like those called *inch bones*; they should then be boiled or steamed for several hours, and the liquor strained; this, on cooling, will be found to form an animal jelly of more or less strength, which may be thickened by boiling, and finally dried into a glue or portable soup, which will keep for a considerable time.

The price of fuel and attendance being calculated, it will be seen whether this operation is a real economy or not: if not, the bones may be allowed to ferment in a heap, being mixed with sand or coal-ashes. In this case, they may be ground at once to the size called half-inch; in the other, they may be passed again through the mill after having been boiled.

Till within the last few years the mode of applying bone-manure to the land has been either by sowing from 20 to 40 bushels of them per acre by the hand broadcast, and harrowing them in with the seed; or by putting them into the drills by a machine made for the purpose, which is an addition to the common drilling-machine. This was the most approved method, and the crop for which they are best adapted is turnips, after the land has been well cleaned and tilled. About 25 bushels per acre was sufficient to produce a good crop on poor light sands, and it did not appear that beyond this quantity they had a proportional effect. It is better therefore to repeat the dressing than to put on much at once. When used as a top-dressing for grass-land, they have produced a great and very durable improvement, when the quantity was large.

When bones used thus were compared with farm-yard dung the result has been various, and chiefly owing to the seasons and the nature of the land. In strong loams or in very moist seasons the farm-yard dung, put on at the rate of from 10 to 15 tons per acre, had decidedly the advantage, not only for the turnips but for the subsequent crops. On very dry gravelly soils and in dry summers the bones produced the best turnips; and when the comparative cost was taken into consideration, and the saving of time in the light carriage of the bones, the bones proved to be the more economical. Many large tracts of waste land have been brought into cultivation by means of bones, as the only manure which could be procured, and without which they must have remained in a barren state. A great advantage of manuring land with them is that they introduce no weeds, which farm-yard dung inevitably does.

The mill which is used to break and grind bones consists of one or more pairs of iron or steel cylinders, with grooves running round their circumference, the projections being cut so as to form strong teeth. These turn upon one another by means of machinery, so that the teeth of one run in the groove between the teeth of the other, as may be seen in the annexed cut.

An instrument has also been invented for distributing bones, ashes, rape-dust, and similar dry manures in the drills at the same time with the seed. It consists of a very simple addition to the common drilling machine, and is described under the word *DRILL*.

The bones put in the hopper *o* are seized by the teeth of the two upper cylinders and broken in pieces, which fall in between the lower pair, where they are reduced to a smaller size. From these they fall on a slanting board *d*, and slide into the wire cylinder. All the smaller pieces pass through the interstices of the wire: those which have not been sufficiently broken come out at the end, and are returned into

the upper hopper. Where a machine of this description can be attached to a water- or wind-mill, or to a steam-engine, the bones are

[End elevation of Bone-grinding Machine.]

[Side Plan of the Bone-grinding Machine.]

A A is the frame of a bone-mill strongly fixed to the floor; *B* the axis of the machinery, which is turned by the lever *c c*, to which the power is applied; *E E* is a horizontal wheel with bevelled teeth moving a vertical wheel *F*, on the axis of which one of the cylinders with grooves and teeth is fixed. At the other end of the axis is a smaller wheel *G*, turning a similar one, *H*, on the axis of the other cylinder, making the toothed surfaces turn towards each other, and thus crushing between them the bones which the hopper *o* supplies. Another pair of cylinders similar to the first, but with smaller teeth, are turned by means of the intermediate wheel *I* working in the wheel *L* fixed to the axis on which is a larger wheel *M*, working in a pinion which turns the cylindrical sieve *N*. The arrows indicate the direction of the motion.

broken at a small expense; when horses are used the expense is greater; and a hand-mill can only be of use where there is a great superabundance of manual labour, and only a small quantity of bones is required.

When reduced to a dust or rough powder by means of such a machine—the bone is the better fitted to feed the plant, just in proportion to the greater quantity of surface exposed to the action of atmospheric solvents, which is thus conferred upon a given quantity of the material. The finer the dust the more rapidly will it yield its substance to the dissolving action of rain-water; and the more competent therefore is a smaller quantity to supply the demands of a crop. The late Mr. Pusey carried this process to its farthest extent by fermenting bone-dust in a heap with damp ashes, mixed with which it heated and crumbled and ultimately acquired the form of a fine powder. It is evident that 1 cwt. of this powdered bone presented to the action of the air and rain as great an available surface off which to dissolve and carry away whatever food for plants the bone contains, as was presented by many cwt. of rough bones or even of crumbled, so-called bone-dust.

It was accordingly found as the result of this process, that 2 or 3

cwts. of bone-dust thus prepared, produced as great an effect upon the turnip crop, as many bushels of the bones in a cruder rougher form.

The fact appears to be as the result of more modern experience, that while the gelatinous part of bone undoubtedly yields by its decomposition valuable fertilising substances, it is to the mineral part of the material—the phosphate of lime, or rather, its phosphoric acid, which it contains—that its fertilising action is mainly due. Every process, therefore, which has increased either the solubility or the liability to solution of this part of the manure, has increased the rapidity and immediate effect of its application. By reducing bones to powder you increase their liability to solution, for you thereby increase the surface wetted by the rain-water. Rain-water contains carbonic acid, and by this acid the phosphate of lime acquires a soluble form, and is ultimately presented liquid to the absorbent roots of plants.

But this solubility can be conferred upon it directly. It was Baron Liebig who suggested that a similar process to that by which soluble phosphoric acid is obtained from bones in the process of manufacturing phosphorus, might be available in the manufacture of a valuable manure. If sulphuric acid be added to bone-dust, the latter becomes to some extent decomposed. A portion of its lime is taken from the phosphate of lime in the bone, and unites with the sulphuric acid; the phosphoric acid of that portion of the phosphate which has been decomposed, unites with the portion of phosphate which has been left undisturbed, and forms a superphosphate; and this is soluble in water. It is the proportion of the resultant manure which is thus rendered soluble that is the measure of the immediate energy and value of the so-called "superphosphate," which is thus prepared for sale and use. Every manure maker now prepares a superphosphate—and a good manure of the kind should contain at least 15 per cent. or more of the soluble superphosphate, and 15 per cent. of the neutral, or natural bone phosphate, together with a small proportion of ammonia, resulting from the gelatinous part of the bone-dust. Where the mineral phosphate of lime, coprolite, or apatite, is used in the manufacture, the neutral phosphate left unacted on by the acid is useless as a manure. Where bone-dust is the source employed of the phosphate of lime, then of course, that portion left unacted on, retaining its natural cellular structure, is still liable to the natural influence of atmospheric solvents, and will continue gradually to dissolve and yield food for plants. In both cases, however, it is the quantity already reduced to a soluble state, which is the measure of the immediate value of the fertiliser. This effect is not due to any power which the manure has thus acquired of at once entering the roots of plants, because the immediate effect of the contact of a soluble superphosphate with the earths present in the soil, is to cause it to resume its original condition of neutral, and therefore comparatively insoluble phosphate of lime. Having, however, once been in a state of solution, it retains in its precipitated state, a condition of so much finer division than any mechanical means could give it, that the superphosphate is as rapid in its action on the crops to which it is applied, as if it retained its solubility throughout.

The effect of this manufacture of superphosphate on the farm practice of the country has been greatly to alter the method of applying bone-dust. Formerly, 24 bushels of bone-dust were applied for the turnip crop per acre—and upwards of one ton per acre was applied in Cheshire to pastures. Now, 3 or 4 cwts. of superphosphate are applied per acre to the turnip crop with an even greater effect.

A good superphosphate as now manufactured ought to contain 18 to 20 per cent. of the soluble phosphate, and 10 to 15 of the neutral phosphate, and from 1½ to 2 per cent. of ammonia. Such a manure is well worth 7½ a ton. It is applied almost exclusively to the turnip crop; being drilled in before the seed—or scattered broadcast before the land is ribbed up to receive the seed. The ordinary application is 3 or 4 cwts. per acre, with a half dressing of ordinary farm manure. It is less useful as a manure for corn crops of any kind; but for green crops, and especially the turnip, it is unrivalled.

BONNET, a name sometimes applied, in permanent fortification, to a work consisting of two faces forming a salient angle which was employed to cover the angle of a *ravelin* when the faces only of the latter were protected by *tenaillons* or *lunettes*; the fire from the bonnet defends the fronts and salient angles of the *tenaillons*, and the faces of the former work are reciprocally defended by those of the latter. [TENAILLON.] When the parapet about the salient angle of any work, as a bastion or ravelin, is raised above the general level of the faces of the work, the elevated part is now occasionally called a bonnet.

BONNET DE PRÉTRE was a term in field fortification, applied by the French engineers to an indented line of parapet having three salient points, on account of some supposed resemblance to the object from which it was named. [REDAN.]

BONZES is the name by which the priests of Buddha are usually designated in Japan. The form of the name in the Japanese language is *bonsan*, which word is supposed by Mr. B. H. Hodgson ('Journal of the Royal Asiatic Soc.,' 1835, vol. ii.) to be a corruption of the Sanscrit *bandya* (*vandya*, 'laudable, deserving praise?') They go with their heads entirely shorn, whence they are often ironically called *kami-naga*, or "long-haired men." The highest in rank is the *daïri*, or spiritual sovereign of Japan, who resides at Miaco. Till towards the conclusion of the 12th century (A.D. 1185) the power of the *daïri* in Japan was nearly absolute; since then the supreme government has become

vested in the *djogoun*, or secular commander-in-chief of the empire, and the influence of the *daïri* in temporal affairs is now next to none, though he still continues to enjoy the honours of a merely nominal sovereignty. (Titsingh, 'Illustrations of Japan,' translated by F. Schobert, London, 1822, 4to.)

The Bonzes are under a vow of celibacy, and form a large corporation of male and female ecclesiastics. They are divided into sects, hostile to each other, and externally distinguished by the colour of their robes. They maintain their influence chiefly by the popular belief in the efficacy of their intercession for others by prayer. Once in every fortnight they deliver a public religious discourse in the temples, usually before numerous congregations. The Jesuit missionary, Gaspar Vilella, who attended several public meetings of this kind, speaks in high terms of the eloquence of the preachers whom he heard, and of their impressive and dignified mode of delivery. Even the female Bonzes are said occasionally to preach.

The Japanese priesthood comprises individuals of all ranks of society. Persons of high birth, even the sons of kings, are known to have entered the order of Bonzes, but the majority belong to the lower and poorer classes. Many Bonzes earn their livelihood by superintending funerals. All claim it as the exclusive prerogative of their order to speak upon the religion of Buddha, the doctrines of which they will not allow to be touched upon by any one else. The principal moral precepts which they inculcate are five, namely,—not to kill, not to steal, chastity, veracity, and abstinence from spirituous liquors; but there are esoteric, as well as exoteric, doctrines held and taught, the mass of the followers being chiefly instructed as to certain formal observances and ceremonies.

There are convents for the male as well as for the female Bonzes, some of which have their own fixed annual revenues, while others are maintained by voluntary contributions from the people. The discipline enforced in these convents is described as rather strict. At different hours during the day the sounding of a bell summons the inmates to their common devotions. In the evening the prefect assigns to every one a special theme for his meditations. After midnight all assemble to sing hymns before the altar. Their meals they take in common, and those who conform strictly to the rule abstain from meat and fish, as well as from wine and all spirituous liquors. Some of the convents are said to contain large libraries.

Gemelli, who visited China in 1695-6, speaks of the three religious sects in that kingdom, and accuses the Bonzes of Buddha of idolatry, and calls them "a pernicious sect," but acknowledges that they teach the soul's immortality and a future state of rewards and punishments. He says theirs is the religion of the commonalty and "the baser sort." He states, also, that they had the greater number of wealthy and beautiful temples as pagodas, and that there were 350,000 who had patents, while the whole number would amount to a million, and that in Pekin there were 10,568 who had no wives, for one of their doctrines was the superiority of celibacy,—and 5022 who were married. Sir John Davis ('The Chinese,' vol. ii.) states that they teach a species of metempsychosis, till the soul is absorbed into nonentity, but that they are not strictly speaking idolaters, as they sacrifice to the invisible spirit, and not to the representation of it in the idol,—a distinction apt to be confounded by their less intelligent followers.

In Siam and Tibet, where the worship of Buddha also prevails, the priests are distinguished in the first as TALAPOINS, in the second as LAMAS.

BOOKBINDING. When books were merely groups of leaves, either of thin skin or some kind of vegetable membrane, the art of the bookbinder was a very primitive one. He had simply to paste or glue the leaves together, so as to form an extended sheet, and to attach this sheet to a cylinder round which it might be rolled. Even to the present day it is customary in some Oriental countries to write on slips of vellum, to sew these slips together into one long sheet or page, and to attach this sheet to rollers at each end, clasped with gold or silver. The square form of binding, now so well known, was of later date, and constituted a very marked improvement; it was adopted largely for the written missals used in Roman Catholic countries, long before the invention of printing, and has been retained as the most convenient mode of binding.

In the binding of a book at the present day, whether humble or costly, there are generally three classes or successive stages of operations, varying in detail according to circumstances, but following each other pretty nearly in regular order. These relate first to the grouping of the sheets together, in a uniform and symmetrical way; next to the fixing of the stiff covers or boards which give firmness to the book; and lastly to those processes which relate rather to the external beauty than to the strength or efficiency of the book. These we shall designate as—1. *Preparing*; 2. *Binding*; 3. *Finishing*; and shall notice the chief varieties as we go on.

1. *Preparing*. A book is built up of several sheets, each folded and re-folded so as to assume a more convenient size than as originally printed. The number of successive foldings depends on the size of the work; thus octavo or 8vo, implies that there are eight printed pages on one side of a sheet, and that the sheet must be so folded as to be brought to one-eighth of its original size. The number whereby the size of a book is designated expresses at the same time the number of printed pages obtained from one side of a printed sheet, such as folio, 4to, 8vo,

12mo, 16mo, 18mo, 24mo, 32mo, &c. In folio there are only 2 pages on each side of a sheet; the others have 4, 8 &c. Some of the sheets employed are larger than others: thus royal octavo, though folded into the same number of pages as post octavo, is larger in size, in consequence of the sheet of paper being larger.

The folding of the printed sheets is one of the first operations in preparing for the binder. Each sheet has a letter at the bottom, such as A, B, &c., for identification; and there are as many of these letters, called signatures, as there are sheets to form the volume. When the alphabet is in this way exhausted, another in smaller type, or duplicate letters, or letters combined with numerals, are employed. There is a heap of signature A, another heap of signature B, and so on. The folder sits before a bench, on which each sheet is spread out in succession; and the folding is aided by the use of a bone or ivory folding-knife: it is done with great rapidity, and with an accuracy which can only result from constant practice. In some establishments a folding-machine has been introduced. The folded sheets are gathered into new groups, fitted to make up into books; that is, each new group is made to contain one copy of the sheet bearing signature A, another of signature B; and so on. The groups are next collated, that is, examined throughout to see that no mistake in the order of arrangement occurs.

If the sheets thus folded, gathered, and collated, are to be put into boards, they are sewn in the next process; but if they are to be bound, and therefore finished in a more careful manner, they are beaten or pressed before being sewn, as a means of bringing them to a more compact and smooth state. Until a recent period this process used to be effected by means of the hammer—the volume being divided into parcels of a few sheets; and these parcels, held flat on a smooth stone, being beaten with a heavy hammer. But the rolling-press has greatly improved the mode of proceeding. This press consists of two smooth steel rollers, rotating nearly in contact; the parcels of a volume are placed between tin plates and then passed between the rollers, the action of which gives them a more effective and expeditious pressure than the hammer. Sometimes, however, the ink becomes 'transferred' to the opposite page by this process, when not properly conducted—to the great disfigurement of the book.

In sewing together the sheets for a volume, they are not actually fastened one to another, but all are in common attached to a range of parallel strings or bands placed across the back of the volume. Sometimes marks are cut with a saw across the back edges of the sheets, to receive the strings; but in other cases these saw-cuts are dispensed with. The process of sewing is carried on by the aid of a sewing-press, which consists of a flat bed or board, two upright bars rising from the ends of this, and a cross-bar at the top. The strings are fastened to the cross-bar and are stretched vertically downwards to the bed of the press, where they are firmly secured. The number of these strings depends principally on the size of the book, and varies from two to eight or ten. The sewer (a female) sits in front of the press, lays a folded sheet down on it, with the back edge in contact with the strings, opens the sheet in the middle, and sews it to the strings, passing a needle and thread to and fro. The needle passes through the back edge of the sheet twice as many times as there are strings; the object being to twist the thread round every string, and thus connect them and the sheet together. The first sheet having been thus treated, a second is laid on the first, and sewn in a similar manner; and so on with a third, a fourth, and as many as there are to form the volume—all the threads being fastened to all the strings, and, indirectly, to each other; for the thread passes from one sheet to another by a peculiar kind of stitch called a 'ketch' stitch.

Binding.—The sheets are by the sewing-process brought together into a book-like form, and are then ready to pass through the operations connected with the boards and covers. The back-edges of the sheets are glued together, to increase the strength of the volume: this is done by simply holding the book in the left hand, and brushing on it a little warm melted glue. The glue being dried, the ends of the strings (which are allowed to hang loose for an inch or so beyond the volume) are scraped thin, for the sake either of being rendered invisible when the book comes to be bound, or else to aid in fastening on the boards. The volume is next rounded in a singular manner; that is, rendered convex on the back and concave or hollow on the fore-edge. The workman lays the volume down flat, and beats it with a hammer held in his right hand, while the left draws the sheets in such a way as to produce the rounding of the edges: the manipulation is a curious one; and as the glue is not yet quite dry, the sheets are enabled to yield a little to the action of the hand and hammer.

A groove is now made to receive the boards or stiff covers. These boards would project beyond the width of the back edge, and would be both unsightly and inconvenient, if some means were not adopted for compressing or confining them. A thin bevel-edged board is placed on each side of the volume far enough from the back edge to allow of a kind of ledge to be formed; these backing-boards, as they are called, are placed parallel with the back edge; and the volume, with these boards on either side, is lowered into a press, with the back edge uppermost. By hammering this edge in a particular way, it is made to expand or spread out, and thus to form two ledges against which the covers of the book are to be placed. Although in common language we consider the covers of a book to be the stiff sides which keep

it firm and compact, yet the terms applied by a bookbinder are rather different. With him, this stiff envelope is called the *board*, the leather or cloth applied outside the board is the *cover*, and the two together form the *case*; and it will be convenient to retain the same terms here.

If the book is to be *boarded*, to use a familiar term, the edges of the leaves are not often cut; but if it is to be bound, this cutting of the edges is an essential process, and is done before the boards are fitted to the volume. The cutting is thus effected: The volume, placed between two boards, is screwed in a press; one of the ends of a volume being left projecting a little above the press. A cutting instrument, called a plough, partaking in some degree of the action of a carpenter's plane, is passed over the end of the volume so as to shave off the ragged edges of the sheets, and leave them perfectly smooth. The volume is reversed in position, and the same thing done with the other end. It is then taken out of the press, and struck forcibly against a bench, so as to bring the convexity of the back and the concavity of the front edge alike to a plane level, which admits of the front edges of the leaves being cut in the same manner as the top and bottom edges had been. The book springs back again immediately on being released from the press: and then presents the neat appearance which a concave front edge, convex back, and plane top and bottom edges, are calculated to give.

Matters are now ready for applying the stiff boards. These are made of millboard, a smooth brown or drab-coloured pasteboard made of several layers of paper glued together and strongly pressed. The sizes and thicknesses vary according to the size of the volume and the kind of binding for which they are to be used. The boards are cut very quickly from the large sheets by a cutting edge applied nearly in the same way as in tobacco-shredding or in chaff-cutting. In attaching these boards to the book, the strength of the fastening depends on the kind of binding. If the book is to be bound, holes are made through the boards, opposite to the strings; and the loose ends of the strings, being passed through these holes, are glued down firmly to the inner surface of the boards, thereby forming a very firm fastening. If, on the other hand, the volume is to be in "cloth boards," the strings are not generally passed through and glued down in this way, but the boards are fastened to the book chiefly by being pasted to the blank leaves or end-papers placed at the beginning and end of the book. These boards, in this latter case, are brought somewhat to a finished state before being attached to the volume; for the cloth is cut to the required size, and handed over to a workman who pastes it upon the two boards, placed sufficiently wide apart to allow for the thickness of the book. Some books, especially in the present day, are made hollow in the back; which is thus produced: A double layer of paper or of cloth is placed between the leather of the cover and the back of the sheets; the leather is glued to the outer layer, and the back edge of the sheets to the inner layer; and as the two layers are connected at their edges, but detached or loose from each other at their surfaces, they give a kind of hollowness to the back of the book.

Most well-bound books have a little appendage at the top of the back-edge, called the head-band. This gives a neat finish to the book, and at the same time strengthens the leather covering of the back-edge at that part. For common books the head-band consists of a cord inserted in silk or cotton; but for better work it consists of a little strip of vellum or pasteboard, around which coloured silken threads are twisted by the same process as that which fastens it to the volume.

When the volume is done in cloth of one uniform colour, the cloth cover is applied to the boards before the latter are attached to the volume; but when it is whole-bound, having leather all over the outer surface, or half-bound, having partly leather and partly paper or cloth at the surface, these coverings are put on after the boards are attached to the book. The leather is cut to a size rather larger than the book, to allow for paring and turning in, and is laid face downwards on a smooth board. The back of the leather is well pasted, and the book placed down upon it, the hands of the workman drawing, and adjusting, and pressing the leather, until it adheres closely to the book in every part. If half-binding be the style of work, then the leather is so cut as to cover the back and a small portion of each board or side; while four small pieces are applied to the corners. The paper or cloth is subsequently so pasted on as to hide the ragged edges of all these five pieces of leather.

Finishing.—By the processes above described, the book has received all which is really necessary for service; the sheets have been arranged in proper order, sewed to strings, fastened to boards, and covered with cloth, leather, or paper. But a large portion of the talent, the ingenuity, and the capital applied to this branch of manufacture is called forth by the subsequent processes to which the book is subjected. These must be rapidly glanced at.

First, with respect to the *edges*. Most persons who purchase books are aware that, if in boards, or cloth-boards, the top edges of the sheets, although placed level, are uncut; while the fore and bottom edges are ragged, uneven, and uncut. In some cases, to make a nearer approach towards neatness, the fore-edge only is cut; in occasional instances, too, the whole of the edges are cut, but left white. But a white edge to a book would soon become discoloured and unsightly; and it is far more usual either to sprinkle the edge with colour, or to

gild it. In sprinkling, the edges of several books are laid on a level one with another, and a piece of sponge, dipped into liquid colour, is passed lightly over the edges, so as to impart the tint to them regularly; this is called *colouring*. A more general method is that of *sprinkling*. The books are in this case ranged side by side on a bench, and a brush dipped in the liquid colour (which is formed of some such pigments as Venetian red, umber, &c.) is held over the books, and lightly tapped against a stick, whereby a shower of spots falls on the edges of the books, producing an appearance depending on the colour employed, and the manner in which the shower of spots is brought about. *Marbled* edges are sometimes produced, by a peculiar admixture and management of different colours sprinkled on the edge of the book.

Gilt edges are more delicate in their preparation. The gold so applied is in the same state as for various ornamental purposes, namely, an extremely thin leaf. Before the case or cover of the book is quite finished, the volume is struck forcibly against the back, so as to make the fore-edge flat instead of concave. It is then placed in a press, with the exposed edge uppermost. The edge is scraped smooth with a piece of steel, and is coated with a mixture of red chalk and water. The gold is blown out from small books, and spread on a leather cushion, where it is cut to the proper size by a smooth-edged knife. A camel-hair pencil is dipped into white of egg mixed with water, and with this the partially dry edge of the book is moistened; the gold is then taken up on a flat kind of brush, and applied to the moistened edge, to which it instantly adheres. When all the three edges have been gilt in this way, and allowed to remain a few minutes, the workman takes a burnisher formed of a very smooth piece of hard stone, and setting the end of the handle against his shoulder, rubs the gold forcibly—not (as might be supposed) endangering its permanence, but giving it a high degree of polish, by rubbing down the minute asperities which may be occasioned by the paper beneath. The gold employed has a greater or less degree of solidity according to the costliness of the book.

The covers have next to be noticed, beginning with those of *leather*. The leather so employed is roan or sheep, calf, Morocco, and Russia; at least, these are the principal kinds, to which alone we need make allusion here. These kinds of leather receive their colour at the dye-houses in Bermondsey, where they are prepared in vast quantities, not only for the London market, but for many other parts of England; but “roan-bound” books, such as school-books, are often sprinkled with colour by the book-binders after the leather has been attached to the boards. For this purpose, the books are opened, and hung over two bars in such a manner that the leaves may hang vertically downwards, while the boards lie horizontal. A brush is dipped into the liquid colour, and dashed or sprinkled on the cover so as to give a group of spots or wavy lines, at the taste of the workman. Calf and Russia leathers do not often receive any modification of surface from the bookbinder; but Morocco is sometimes treated in the following manner. The Morocco leather employed for chair-covers and such purposes is made either of kid-skin or sheep-skin according to its quality, and has a wrinkled appearance, arising from the surface having been rubbed very hard with a minutely grooved piece of wood. Now for many purposes of bookbinding these wrinkles are changed to a granulated appearance, by the following process: Two pieces of leather being well wetted, and laid face to face, the upper one is rubbed in different directions with a flat piece of cork, by which the wrinkles are removed, and a slightly granulated texture produced.

The decorations produced on a leather-bound book by heated stamps or dies are very diversified. The dies for producing any particular device are fixed to handles, and when about to be used are warmed in a gas-heated stove. Many such dies are often used for one book, and the process of producing a sunken ornamental device by using these tools by hand is called *blind-tooling*. But for many purposes it is more convenient to fasten a great number of small dies as partial devices to a metallic plate, by means of glue and cloth, and to stamp the device from this fixed plate by means of a press; this is called *blocking*.

All the devices so produced on a book are called “blind,” if no gold be employed; but much of the beauty of the workmanship depends on the tasteful introduction of this metal in forming part or all of the pattern. The leather, as laid on the book, is not in a fit state for receiving the gold without some modification of surface. It first receives a coating of parchment-size; then two or three coatings of white of egg, whereby a slight glossiness is produced; and just before the gold is to be laid on, the surface is slightly moistened with oil. The gold, cut up into small pieces, to suit the kind of ornament, is laid on the book with a flat camel-hair brush; and the stamp or die, previously heated in the fire, is impressed on the gold; whereby two effects are produced at once—the production of the device, and the fixing of the gold to the leather. A piece of soft rag, lightly passed over the book, removes the small superfluous fragments of gold, and leaves the gilt device clearly marked.

But the decoration of volumes bound in cloth, although occupying a far lower level in respect of manual dexterity than the more costly binding in leather, has occupied much attention within the last few years, and has been one of the means for producing neat and even elegant volumes at a marvellously low price. Cloth-binding, in fact, has been the germ of one great advance in the art—the application of machinery to much that had previously been effected by manual labour.

The cloth with which books are covered is generally cotton of a particular kind, woven for the purpose. When the system of cloth-binding came up, about thirty years ago, the cloth was used in the unaltered state, with the warp and weft threads visibly crossing each other at right angles. But now the cloth is more generally so altered by an artificial embossment of surface, as to leave the threads barely visible, and to give to it a close resemblance to leather. The cloth covers for many books have now imparted to them, by embossing, a remarkably close resemblance to the appearance of leather; a resemblance which, though now becoming very common, would have deceived many an eye a few years ago. This embossing is produced by drawing the cloth, while yet uncut for the purposes of binding, between two steel rollers, of which the surfaces are engraved with the required device, and which have a row of gas-jets through their hollow centre, to keep up a constant temperature. There must be as many pairs of rollers as there are different devices for embossing cloth; so that the number in large factories is very considerable. Some of the rollers are intended for the production of a uniform device over the whole surface of the cloth; while others have particular devices for each particular book, and are consequently planned with especial reference to the size of the volume. The rapidity with which books can be now bound in this way, is one great cause of the surprising cheapness at which they are often sold. Paper-wrappers for stitched but unbound books can of course be applied much more quickly. One of the most notable examples of this kind ever known, was afforded by the Great Exhibition of 1851. At ten o'clock in the evening of the 30th of April, the first complete printed copy of the Official Catalogue left the printer's hands; in the following forenoon *ten thousand* such copies were ready at the Exhibition building in Hyde Park, including two superbly bound, for Her Majesty and Prince Albert.

Other kinds of cloth covers, especially those which are much decorated with gold, are stamped with the device *after* being pasted on the covers, instead of before; they are, in fact, *cases*, each one quite ready to affix to the book in a speedy manner after being stamped. Great pressure is required in this process, for the mill-board is required to yield to the force, as well as the cloth itself. The case is placed down flat on an iron bed heated with gas from beneath; above is a press, to the lower end of which is attached the stamping-die or device, face downwards. Great mechanical power is then brought to bear on it, and the press descends with force sufficient to impart the pattern to the cover, gilt or not, according to the circumstances of the case.

India-rubber Binding.—The last few years have witnessed the introduction of a singular mode of binding, arising out of the use of a cement or glue of caoutchouc, instead of sewing, for fastening the sheets of books together. In this process, the sheets are not allowed to retain the folded form customary in other kinds of binding; but the edges are cut on *all four* sides—on the back as well as the front, top, and bottom; the consequence of which is, that all the leaves are separated one from another. The group of leaves to form one volume is placed in a kind of gauge, by which convexity is given to the back-edge and concavity to the front; and a cement of caoutchouc is carefully applied to the back-edge, whereby all the leaves become cemented together. The subsequent operations are much the same as in other binding. There is a certain kind of flexibility resulting from this method, advantageous when the volume is thick. This method was introduced by Mr. Hancock, and in reference to it the late Dr. Ure remarked:—“For engravings, atlases, and ledgers, this binding is admirably adapted, because it allows the pages to be displayed most freely, without the risk of dislocating the volume; but for security, three or four stitches should be made. The leaves of music-books bound with caoutchouc, when turned over lie flat in their whole extent as if in loose sheets, and do not torment the musician like the leaves of the ordinary books, which are so ready to spring back again. Manuscripts and collections of letters which happen to have little or no margin left at the back for stitching them by, may be bound by Mr. Hancock's plan without the least encroachment upon the writing. The thickest ledgers thus bound open as easily as paper in quire, and may be written up to the innermost margin of the book without the least inconvenience.”

A method was patented, some years after the introduction of india-rubber binding, under the name of “Cement-binding.” This consists in cementing the leaves or sheets together at the back, with a composition of isinglass, oil, sugar, and other ingredients; and in covering the cemented edges with a strip of calico similarly cemented. What advantages (if any) this possesses over the caoutchouc binding, does not appear: its principle is evidently the same.

Palmer's patent binding consists in applying small brass bars, linked together, to the back of the book, in such a manner that they make the different sections of the book, when open, parallel with each other, and thus admit of writing readily on the ruled lines near the back. It seems to be another mode of attaining some such result as that which is aimed at in india-rubber binding.

Williams's patent binding consists in the employment of a back, curved in form, turned a little at the edges, and made of metal, ivory, or wood. This back is adjusted to the book before it is bound, in such a manner that it may just cover but not press upon the edges, and is fastened on by enclosing it in vellum or ferret wrappers, which are pasted down upon the boards, or drawn through them. The object is

to make the book open freely and evenly, and to prevent it from spreading on either side.

There have been other recently-patented novelties in book-binding; but instead of dwelling upon them, we will make a few observations on the condition of the art generally.

The finest specimens of modern book-binding ever seen in this country were probably those in the Great Exhibition of 1851. The Report of the Jury on "Paper and Books," noticed the attempts which have been made to adapt the style of book-binding to the subjects of the books. Those attempts have in some cases been directed to particular colours of the leather or cloth; but more generally the style of ornament has borne relation, real or supposed, to the subject-matter treated in the volumes. For example: characteristic emblems or symbols have been adopted among the gilt or stamped adornments; and ornaments of Egyptian, Roman, Grecian, Gothic, or Saracenic character have been used in works relating to the history or geography of those countries. It is generally admitted, however, that our bookbinders do not attend much to this subject. The Jury gave the following interesting notice of some of the steps whereby the rapid book-binding of modern times has been rendered possible:—"Mr. Burn, of Hatton Garden, first introduced rolling-machines to supersede hammering. The iron printing presses of Hopkinson and others were altered to form arming-presses, by which block-gilding, blind-tooling, and embossing can be effected with accuracy and rapidity. Leather covers, embossed in elaborate and beautiful patterns by means of powerful fly-presses, were introduced by M. Thouvenin, of Paris, about twenty-five [now nearly thirty-five] years ago; and almost simultaneously in this country by Messrs. Remnant & Co., and by Mr. De la Rue, who were quickly followed by others. Embossed calico was also introduced about the same period by Mr. De la Rue. Hydraulic presses, instead of the old wooden screw presses; Wilson's cutting-machines, which superseded the old plough; the cutting-tables with shears, invented by Mr. Warren de la Rue, and now applied to squaring and cutting millboards for book-covers,—all these means and contrivances, indispensable to large establishments, prove that machinery is one of the elements necessary to enable a binder on a large scale to carry on that business successfully."

Before closing this article, it will be desirable to notice briefly some of the points treated in an interesting paper read before the Society of Arts, in February, 1859, by Mr. John Leighton:—"On the Library, Books, and Binding, particularly with regard to their Restoration and Preservation." Dust and dirt upon books in a library affect the binding in a way that may easily be understood, and needs no comment. Dampness occasions the frequent disfigurement of books, both in the paper and the binding, with spots like iron-moulds, which will ruin the volume if left unremedied. Dry heat is even worse than damp for the leather of binding. In the library of the Athenæum Club, the calf and Russia bindings were found some years ago to have suffered so severely, by the effect of a gas-lighted room, that in many cases they crumbled under the touch, the backs fell away, all the oily matter seemed as if dried out of the leather, and a general deterioration was visible. Mr. Faraday, to check the spread of the evil, introduced a gas-burner with a chimney for conveying the deleterious fumes to the outer air; but Mr. Leighton expresses an opinion that it is better in all cases to use oil-lamps in a library—so far as the books are concerned. In old libraries, the ravages of a peculiar kind of book-worm are well known to bookbinders and biblioplists. An instance has been recorded where, in a range of books very seldom consulted, twenty-seven adjacent folio volumes were found perforated by a worm-hole, so direct and thorough that a string could be passed through the whole thickness of all the volumes, paper and binding included. Some kinds of leather suffer more than others from insects and worms; and in hot countries, the paste and glue of ordinary bindings become unfortunate sources of destruction. Mr. Leighton thinks that modern ordinary mill-board, made of well-tarred rope, is as good a material as can be found for the groundwork of book covers; he makes some useful comments on the often-suggested use of corrosive sublimate, colocynth, starch, alum, vitriol, salts of ammonia, orpiment, and other substances, as preservatives of books against insect-visitations; and he hints that an occasional atmosphere of tobacco-smoke may be useful in this matter. Mr. Leighton made the following observations on the chief kinds of leather used in bookbinding:—"Many books of the mediæval period are bound in vellum and leather, without millboards. Formerly a pasteboard was used, made of the rudest materials—paper, cloth, old vellum, or what not. The earliest leather covers were principally of a rich brown calf, undyed; and so they remained until the early part of the present century. All the stains then in vogue were imparted to the skin by the bookbinders; who, by the judicious application of them, produced very beautiful natural effects—tree marbles, sponge dabs, sprinkled and spotted patterns—innumerable, though not always without injury to the leather, the surface of which the stronger acids were apt to burn after some years' action. The plain dyes given to calf in the whole skins have tended to supersede the colouring of leather on the volume itself. The old, simple, undyed calf was exceedingly good and strong; being more durable than many of the fancy-hued hides of the present day, which seem to have the elements of decay therein before being put on the volume, and which are even afterwards washed by the binder with oxalic acid,

imparting a delicacy of surface most injurious to the skin. This is clearly evidenced in the binding of law-books, uncoloured calf being always used (which, in combination with the white edges, is, I believe, intended as typical of the purity of the profession); the leather being washed up with spirit to a fictitious whiteness, rendering it in a few years rotten, as many law libraries will sadly testify. Morocco, the earliest coloured old leather, is decidedly the strongest, richest, and best for the binder's art; it is surface-dyed goat's skin, and no doubt first came to England on Venetian books, when that Republic was in its glory. It is the prince of leathers; having received the greatest and choicest amount of decoration, the most delicate and boldest of hand-tooling. Hog-skin is a nice and durable material for bookbinding, though not much used; it takes blind-tooling admirably. Russia, unless used extremely thick, is a poor and rotten leather; being little stronger than paper if pared thin, and only to be prized on account of its odour, and pleasant tint of colour. In bookbindings of the present day, leathers are pared and shaved much too thin, especially where strength is most required—at the joints, near the head-bands; this is by no means necessary, if the leather be turned in the entire thickness, space being cut for its reception in the board—a plan I have always adopted for heavy books. Vellum is extremely strong and useful to the binder, though from its rigid nature hardly adapted to book-joints—at least, as books are bound or forwarded (as it is termed) at present; unless it be those of account-books, where all strong materials, from hard writing-paper to horny bands of leather, are most prized. Vellum bookbinding for bankers, &c., is a distinct branch of trade, apart from bookbinding proper; in the binding of printed books it is somewhat difficult to get a whole vellum cover to set well, it being a material better suited to immoveable parts, as edges, corners, linings, and inlayings." In a discussion which followed the reading of Mr. Leighton's paper, it was stated that the bound books of the London Institution, of the library of the Earl of Tyrconnel at Kilpin, of a room in the 'Times' office, of the Royal College of Surgeons, of the Literary and Philosophical Society at Newcastle on Tyne, of the Alfred Club, and of the libraries belonging to other individuals and corporate bodies, had all suffered in the same way as those at the Athenæum Club, by the use of gas-lights or gas-stoves.

BOOK-KEEPING. Book-keeping by double entry is the art of keeping accounts in a scientific manner.

So much obscurity surrounds the early history of the art that it is impossible to discover either by whom, or at what period, it was invented. Some are of opinion that it was known in Europe as early as the beginning of the first century, but the passages in the classical authors are inconclusive on which this opinion is based. Others assert that it has been practised by the Banians of India from time immemorial, and that it was by them communicated to the Venetians in the 15th century; while others again say that the Venetians learned it from the Arabians. However this may be, it is certainly to the Venetians that we are indebted for our knowledge of the art. The earliest known treatise on the subject is that of Lucas de Burgo, which was published in the Italian language in the year 1495, from which circumstance book-keeping by double entry has acquired the designation of the Italian method.

Italy—at this period the great centre of the world's commerce—evidenced its appreciation of the art, by producing several works on the subject in quick succession. In the beginning of the 16th century the art was introduced into France; and in the year 1543 Hugh Oldcastle, a schoolmaster, published the first treatise in this country.

More than one hundred and fifty works on book-keeping have been published in the English language since that by Hugh Oldcastle, but the number of those which merit unqualified praise is not large. The earlier works, indeed, were extremely crude and unsatisfactory; and it was not till the year 1789, when Mr. Benjamin Booth, a merchant of intelligence and experience, published his 'Complete System of Book-keeping,' that we could be said to possess a thoroughly practical exposition of the principles of the science.

The theory of double entry has been repeatedly assailed both in this country and on the continent, and by none more ably than by Mr. Edward T. Jones, an accountant of Bristol, who first attacked it soon after the appearance of the work by Mr. Booth, to which we have just referred. Mr. Jones's object was two-fold—first, to overthrow the Italian system, which he contended was fallacious, and secondly to establish in its stead a system of his own invention, which he represented to be infallible. The method recommended by Mr. Jones is known as the English system of book-keeping.

Mr. Jones's announcement excited considerable attention in the commercial world, and resulted in a large subscription being raised for his encouragement. In the year 1796 a patent was granted to him for his invention.

The expectations raised by that invention, however, were not fulfilled; and although Mr. Jones has left us two greatly enlarged and improved editions of his original work, the Italian method has maintained its ground as the favourite method of book-keeping, and is still employed by the first merchants of Europe and America.

It is much to be regretted that in a country so renowned as this is for its wealth and commerce, book-keeping should not be more generally and intelligently studied. Unfortunately a notion prevails

that it is a complex and arbitrary system without any fixed principles or any intelligible rules. Nothing, however, could be more erroneous. Book-keeping is a system of as great perfection and beauty as anything human can be, and it is based upon principles which are simple, unalterable, and capable of universal application.

When its importance and true character shall come to be properly understood, book-keeping will undoubtedly be recognised as a necessary branch of general education; and to be ignorant of the science of accounts will be held to be scandalous, not only in the trader, who should be the guardian of his own interests, but also in directors of companies and guardians of charities, to whom are entrusted the interests of others. There are but few persons who have any adequate conception of the number of bankruptcies which have resulted from irregular accounts alone, or of the extent of the waste, peculation, and frauds which the absence of an intelligent scrutiny of accounts has first encouraged, and afterwards concealed.

It is deserving of notice that of late years the executive government has done much to promote the study of book-keeping in this country. The Lords of Her Majesty's Treasury have made a competent knowledge of the art an indispensable qualification, in candidates for certain branches of the civil service; and the Poor Law Commissioners for England and Wales, in the year 1847, issued an able order prescribing the accounts to be kept in all the Poor Law Unions under their control.

Book-keeping by double entry is alike applicable to the accounts of merchants, manufacturers, traders, public companies and bodies, and private individuals; but for the sake of brevity, we shall confine our remarks to accounts of the first-mentioned class.

The first necessity is that the merchant should secure a record of every fact and transaction affecting his property.

Formerly this record was kept in a book known as the Waste-Book, but experience having shown the inconvenience of a register in which no regard was paid to the classification of the entries (purchases and sales, payments and receipts, being jumbled together), the Waste-Book is now subdivided by every merchant according to the nature of his business. A common division of that book is the following:—

- I. THE DAY-BOOK, or INVOICE-BOOK OUTWARDS, in which the merchant records his sales *on credit*. Should he sell any of his goods for cash, he must enter those sales separately in a CASH SALES-BOOK.
- II. THE INVOICE-BOOK INWARDS, in which he records his purchases *on credit*. A common mode of keeping this book is to paste into it the invoices in the order in which they are received.
- III. THE CASH-BOOK, on the left-hand side of which he enters all cash received, and on the right-hand side all cash paid. Discount received and allowed is sometimes shown in inner columns of this book.
- IV. THE BILL-BOOK, in one part of which he records all the bills *receivable*, and in another part all the bills *payable*.
- V. THE STOCK-BOOK, or INVENTORY, in which he enters an account of his stock on hand at the time of the balancing of his books.

All the books of this class are perfectly simple in their character, and when properly kept contain all the necessary data for the correct statement of the accounts in the Ledger—a book of which we shall speak presently—hence they are called *subsidiary books*.

Too much care cannot be bestowed on the selection and preparation of the subsidiary books, so as to adapt them to the particular business in which the merchant is engaged. The subsidiary books of a trader will differ from those of a merchant, and these again will differ from the subsidiary books of a broker. The object, however, of the subsidiary books is in all cases the same, namely, to obtain a classified record of every fact affecting the property of the individual.

Now, double entry addresses itself to the collection into a book called the LEDGER, of all the facts scattered through the subsidiary books, and to the arrangement of those facts in that book with such accuracy and conciseness as to show at a glance the precise state of the merchant's affairs. The supreme importance of this book—in which the accounts take their ultimate and scientific character—will be readily perceived.

The accounts in the Ledger are divided into

- I. Personal accounts.
- II. Real accounts.
- III. Fictitious accounts.

I. The Personal accounts are those opened with the persons with whom the merchant has dealings *on credit*. These accounts show him whether those persons owe him anything, and if so how much, or whether he owes them anything, and if so how much.—See Ledger accounts, 9, 10, 11, and 12.

II. The Real accounts are the accounts of his property, and show how, where, and in what proportions it is invested. It is in the nature of a merchant's transactions that his property should be in a state of constant change. His cash of to-day may be merchandise

to-morrow, and the bills receivable of to-morrow may be cash on the third day. The Real accounts show these changes in his property.—See Ledger accounts, 2, 3, 4, 5, 7, and 8.

III. The Fictitious accounts are those showing his gains and losses; but why these accounts should be called fictitious it would puzzle any one—and we therefore will not attempt—to say.—See Ledger accounts, 1, 13, 14, and 15.

Double entry takes its stand upon the scientific axiom, that “the whole is equal to the sum of all its parts;” or, conversely, that “all the parts taken together are equal to the whole.” An examination of the following Stock account will show that that account exhibits “the whole” of the merchant's property, taken collectively; and an examination of the remaining accounts will show that they exhibit “all the parts” of his property taken separately. It follows therefore that all the *parts* as represented by such remaining accounts must in all cases be equal to the *whole*, as represented by the Stock account. This is the distinguishing feature of double entry; it records all its facts, and arrives at all its conclusions by a *double process*, the one process operating as a check upon the other.

This brings us to the fundamental principle of double entry, which is that every fact carried to the Ledger must be entered *twice*, that is, on the Dr., or lefthand side of one account, and on the Cr., or righthand side of another account. *The account giving out the item is always the Cr., and the account receiving it is always the Dr.* By this means the aggregate amount of all the debtors in the Ledger is at all times equal to the aggregate amount of all the creditors. The accounts are thus kept in a state of constant equilibrium. An illustration of this truth is given in the *Journal*.

It is the practice of book-keepers, before closing their accounts at any given period, to ascertain by adding up both sides of their Ledger, whether an equilibrium of debtors and creditors has been duly preserved, and this is called making a *trial balance*. If an equilibrium has not been preserved at every stage of the posting of that book, the accounts cannot be correct.

We will now give a concise exemplification of the foregoing principles.

For this purpose let us suppose that we want to know the state of a merchant's affairs on a given day, say the 31st of January. We turn to his subsidiary books and find that when his position was last ascertained (say on the 1st of January), it was as follows:—

ASSETS.

	£
Cash	500
Wine (50 pipes, valued at 70 <i>l.</i> per pipe)	3,500
Merchandise (exclusive of wine) valued at	10,000
Bills receivable	100
M. Moythan owes	100
Sugar in Co. valued at	300
	£14,500

LIABILITIES.

	£
Bills payable	150
J. Jenks, due to him	50
	£200

By his Day-Book we find that he has since sold 500*l.* worth of goods and 2000*l.* worth of wine to M. Moythan, and 1500*l.* worth of goods to J. Jenks; and that he has sent 200*l.* worth of goods to Hull on speculation, the charges on which amounted to 10*l.*

By his Invoice-Book we find that he has purchased 200*l.* worth of goods from R. Lloyd, and 400*l.* worth from T. Nott.

By his Cash-Book we find that he has *received* 2600*l.* from M. Moythan; 1200*l.* from J. Jenks; 190*l.* from his adventure to Hull; 50*l.* in payment of one of his bills receivable; and 350*l.* for the sugar in company; and that he has *paid* 100*l.* in discharge of one of his bills payable, and 80*l.* for rent and wages. On turning to his Bill-Book we do not find that he has either issued or received any bill during the month.

To facilitate the posting of the Ledger from the subsidiary books, an intermediate book is used called the *Journal*, the object of which is to indicate to what accounts, and to which side of each account, the transactions recorded in the subsidiary books are to be carried. In the infancy of the art it was customary to post and journalise each transaction separately, but experience having shown the inconvenience of that practice, it has long been discontinued. The practice which now obtains is to journalise the transactions *monthly* instead of daily and to include in one entry all the transactions of the month belonging to the same class. Thus, instead of journalising each item appearing on the Dr. side of the Cash-Book separately, all the cash receipts of the month are entered together as *Cash Dr. to Sundries*, the word *Sundries* always meaning in book-keeping not sundry or several articles but sundry or several accounts. By this contrivance there never can be more entries in the Ledger account than *twelve* on each side, namely *one* for each month in the year.

THE JOURNAL.

DRS.			LONDON, January, 1859.			CRS.		
£	s.	d.	SUNDRIES DR. TO STOCK			£	s.	d.
500	0	0	Cash.			14,500	0	0
3,500	0	0	Wine.					
10,000	0	0	Merchandise.

THE LEDGER ACCOUNTS.

1.

DR.		STOCK.		CR.	
January 1	To Sundries	£ s. d.	January 1	By Sundries	£ s. d.
" 31	To BALANCE for present worth . . .	200 0 0	" 31	By Profit and Loss	14,500 0 0
		14,887 0 0			587 0 0
		£15,087 0 0			£15,087 0 0

On the opening of the books this account is credited with the total amount of the merchant's property, and debited with the total amount of his liabilities; the difference being his net worth. No further entry is made in this account until the Ledger has to be balanced.

2.

DR.		CASH.		CR.	
January 1	To Stock	£ s. d.	January 31	By Sundries	£ s. d.
" 31	To Sundries	500 0 0	"	By Balance	180 0 0
		4,390 0 0			4,710 0 0
		£4,890 0 0			£4,890 0 0

At the commencement of the year, Stock gave out 14,500l. to the several branches of the business. Stock therefore was credited with that amount, and Cash, Bills, &c., debited with the proportions of that sum which they respectively received. This account is debited with all cash coming in and credited with all cash going out, the difference being the amount of the cash in hand.

8.

DR.		ADVENTURE TO HULL.		CR.			
January 31	To Merchandise	£	s. d.	January 31	By Cash	£	s. d.
" "	To Charges	200	0 0	" "	By Profit and Loss for Loss	190	0 0
		10	0 0			20	0 0
		£210	0 0			£210	0 0

This is the account of the goods which the merchant sent to Hull. It is *debited* with the value of the goods, and with the expenses attending the adventure, and *credited* with the returns. In this case, the returns fell short of the outlay; the difference is therefore loss, which must be entered on the Cr. side of this account, and from there carried to the Dr. side of Profit and Loss.

9.

DR.		M. MOYTHAN.		CR.			
January 1	To Stock	£	s. d.	January 31	By Cash	£	s. d.
„ 31	To Merchandise	100	0 0			2,600	0 0
„ „	To Wine	500	0 0				
		2,000	0 0				
		£2,600	0 0			£2,600	0 0

This and the three following are Personal accounts. In each case the person is *debited* with what he receives, and *credited* with what the merchant receives from him. In this case the two sides of the account are equal, the account is therefore clear.

10.

DR.		J. JENKS.		CR.			
January 31	To Merchandise	£	s. d.	January 1	By Stock	£	s. d.
		1,500	0 0	" 31	By Cash	50	0 0
				" "	By Sugar in Co. for $\frac{1}{2}$ Profits	1,200	0 0
				" "	By Balance	23	0 0
						227	0 0
		£1,500	0 0			£1,500	0 0

In this case the Dr. side is the greater, therefore J. Jenks owes money to the merchant.

11.

DR.		R. LLOYD.		CR.	
January 31	To Balance	£ s. d. 200 0 0	January 31	By Merchandise	£ s. d. 200 0 0

In this case the Cr. side is the greater, therefore the merchant owes money to R. Lloyd.

12.

Dr.		T. NOTT.		Cr.	
January 31	To Balance	£ s. d. 400 0 0	January 31	By Merchandise	£ s. d. 400 0 0

This account is precisely similar to the preceding account.

13.

Dr.		CHARGES.		Cr.	
January 31	To Cash	£ s. d. 80 0 0	January 31	By Adventure to Hull	£ s. d. 10 0 0
			" "	By Profit and Loss for Loss	70 0 0
		£80 0 0			£80 0 0

All expenditure in respect of which no returns are received, such as rent, wages, interest of money borrowed, &c., may be placed *direct* to the *debit* of Profit and Loss; and all receipts in respect of which no property is exchanged, such as commission and discounts, may be placed *direct* to the *credit* of Profit and Loss, or separate accounts of them may be opened, and only the balance transferred to that account when the books are to be balanced. In this exemplification we have taken the first course with respect to *Commission*, and the second course as regards *Rent* and *Wages*.

14.

DR.		PROFIT AND LOSS.			CR.				
	<i>Losses.</i>	£	s.	d.		<i>Gains.</i>	£	s.	d.
January 31	To Adventure to Hull	20	0	0	January 31	By Wine	250	0	0
"	To Charges	70	0	0	"	By Merchandise	400	0	0
"	To STOCK for net gain	587	0	0	"	By Sugar in Co.	27	0	0
		£677	0	0			£677	0	0

This is the account in which all the merchant's gains and losses are collected together, the losses on the Dr. side, and the gains on the Cr. side. The Gains less the Losses give the merchant's net gains, which must be carried to his Stock or Capital account.

15.

DR.		BALANCE.			CR.				
	<i>Assets.</i>	£	s.	d.		<i>Liabilities.</i>	£	s.	d.
January 31	To Cash	4,710	0	0	January 31	By Bills Payable	50	0	0
"	To Wine	1,750	0	0	"	By R. Lloyd	200	0	0
"	To Merchandise	8,800	0	0	"	By T. Nott	400	0	0
"	To Bills Receivable	50	0	0	"	By STOCK for present worth	14,887	0	0
"	To J. Jenks	227	0	0					
		£15,537	0	0			£15,537	0	0

The Balance-Sheet is drawn out when the merchant wishes to ascertain the state of his affairs, and is a collected statement of his assets and liabilities. His assets are found in the balances appearing on the Cr. side of the Ledger accounts, and these are all brought to the Dr. of the Balance-Sheet. His liabilities are found in the balances appearing on the Dr. side of his Ledger accounts, and these are all brought to the Cr. side of the Balance-Sheet. The difference between his assets and his liabilities is his present worth, which must be entered on the Cr. side of the Balance-Sheet, and from there carried to the Dr. side of the Stock account. The Profit and Loss account and the Balance account are closed by the Stock account.

The reader will now observe, on reference to the latter account, that we have arrived at the merchant's present worth by two distinct processes: 1st. By adding his net gains to his original net capital; and, 2nd. By deducting his liabilities from his assets: and that the result by each process is the same. He will further observe that the two sides of the Stock account are now equal, in which fact we find satisfactory evidence that the accounts are correct.

Partnership accounts are kept in precisely the same manner as the accounts of a single trader. But in partnerships the Stock account represents THE CONCERN, and Personal accounts have to be opened with each of the partners. These personal accounts are credited with what the partners respectively bring into the concern, and debited with whatever they draw out. At the balancing of the books the profits are divided, and the share of each partner is brought to the credit of his account.

Book-Keeping by Single Entry.—In book-keeping by single entry, the transactions recorded in the subsidiary books are entered *once* to some account in the Ledger, instead of *twice*, as in double entry. Single entry is employed by many retail traders, but it is an unscientific and unsatisfactory system, and wholly inadequate to the statement of complex transactions.

BOOT AND SHOE MANUFACTURE. Scarcely any handicraft employment engages the attention of so many persons in this country as boot and shoe making. From the artist of aristocratic circles, to the cobbler who rolls himself up in a stall under a pot-house, is a wide interval; and this interval is filled up by numerous grades. At Northampton and Stafford, boots and shoes are made on a very large scale for the London market; they include chiefly the cheap varieties; but at some of the recent exhibitions of manufactures the Northampton boot-makers have exhibited specimens of workmanship which are considered to fall in no way behind those of London or Paris. In various country towns the strong coarse 'hob-nailed' shoes are made, which are so much worn by waggoners and others. The London makers import from Paris very large quantities of boot fronts, which when combined with other parts of English manufacture, constitute many of the 'French boots' which now glitter in the windows.

The mechanical details of the manufacture have been well described by Mr. Devlin; who, in his 'Shoemaker,' forming one of the 'Guides to Trade,' has contrived to throw a general interest into that which would otherwise be merely technical. The processes of cutting and sewing the leather are, however, not of such a nature as to call for detailed description here.

Many improvements or suggested improvements in boot and shoe making have been patented within the last few years. M. Lefébre, of

Paris, has introduced boots and shoes, the soles and heels of which require no stitching. Machinery is employed, whereby the sole and the heel are fastened to the welt by brass screws; the closeness of contact being equal (as is said) to a pressure of two or three cwt. Some of our readers may remember that one of these boot-screwing machines was displayed at the Great Exhibition of 1851. Mr. Waite, a London manufacturer, patented a few years ago a series of machines to supersede the necessity for clickers, in cutting out women's and children's boots and shoes. The advantages of the apparatus are said by the inventor to be, that six hundred dozens of boot-linings can be properly prepared for the binders in twelve hours; and that the skins used in the manufacture can be prepared for the binders in one-tenth part of the time usually required, and at a less expense. The same manufacturer has also invented a machine for modelling instep-pieces for women's and children's boots and shoes. Another recent machine is Mansell's blocking apparatus, to effect the blocking of a boot in much less than the usual time, and with less injury to the leather. A piece of leather, cut to the proper shape for the front of a boot, is well soaked in water; a small quantity of 'dubbing' (a kind of oily paste-black) is spread on that part of the front which corresponds to the instep; and the leather so prepared is laid on the upper surface of two iron cheeks. A winch is then turned; and, with the assistance of cog-wheels, the leather is brought down between the cheeks by a plate of zinc, and descends below the cheeks. This operation is repeated according to the strength of the leather. Another invention, by Mr. Marsden, relates to ventilating openings at the sides, kept open by small metallic plates. Among the other novelties are Durenville's system of machinery for cutting and making boots and shoes; Hetley's plan for producing shoe-leather by a curious combination of leather raspings with india-rubber and gutta percha, pressed into blocks, and sliced; a plan for sewing together the different parts of a boot or shoe with 'wire thread instead of hempen thread'; and a curious adaptation of revolving circular heels, which may be turned round in order that every part may receive equal wear.

The principal recent novelties in boot and shoe making, however, result from the use of india-rubber or gutta percha. Gutta percha, applied for under-leathers, is found serviceable in withstanding moisture; though it is not adapted for hot and dry climates. The American over-shoes, made entirely of vulcanised india-rubber, will withstand both moisture and heat, and are much worn as clogs or temporary coverings for other boots or shoes in inclement weather. In other instances, india-rubber is applied to give elasticity to certain parts of a boot; and the so-called 'resilient,' and 'siccopedean,' and 'tei-ideo-elasticon' boots and shoes, are simply applications of this elastic substance where it may be most useful. As a proof of what may be effected by the use of this material, a pair of boots for a jockey has been made weighing only three ounces. One inventor has devised a mode of introducing a layer of gutta percha between the outer and inner soles; and another has proposed the use of heels made of an iron rim, with the vacuity filled up with gutta percha.

Boots and shoes for the army deserve more attention than they have received. The late Sir M. I. Brunel invented a most ingenious system of machinery for manufacturing soldiers' shoes with great rapidity; but the plan, through some deficiency in its results, was never very extensively adopted. Mr. Dowie at the present time makes soldiers' shoes, with a peculiar elastic piece between the sole and heel, to enable the shoe to accommodate itself to the bending of the foot in walking.

During the Crimean war, the sufferings of the troops were greatly and unnecessarily increased by the shameful quality of the boots and shoes supplied to the army by some of the contractors. Mr. Medwin, an experienced boot-maker, in a letter to the 'Times,' detailed in the following terms some of the causes of this unsuitableness. Referring to water-boots for wet weather, he said: "The straps used for these have been a piece of narrow cotton tape, breaking after two or three times of trial, and causing the boots, especially if damp, to pull on with much difficulty. A leather strap substituted for the cotton tape would cost no more, and would last out the boot. The inner sole, or that on which the foot rests, being a part not seen, is generally in an untanned, or nearly in its raw green state; the effect of this is inevitably to blister and draw the feet; and when this crude leather is drying, after the boot has been damp or in water, materially to shrink and contract it. Through carelessness or want of judgment the seams in the shorter boots are so placed as if purposely to cut like a tightened cord over the most tender parts of the foot: and this where there is most exposure to the weather, and where also the work is most likely to come undone, and to be difficult of repair. If the boot were properly contrived, no seam would be needed across this susceptible portion of the foot; all pressure would be thus got rid of, and one fruitful cause for the necessity of repairs removed. I venture to affirm that, so far as the structure of the foot is concerned, our army boots are fully a century behind the improvements of the day—loose, where a hold upon the foot is needed; and consequently tight across the articulated portions of the foot, where ease, play, and freedom are especially required." He affirmed that well-made and well-fitting boots and shoes might be supplied to the army at prices not exceeding those now paid by the nation for ill-made articles. An inquiry made in 1858, by a body of special commissioners, into certain defalcations at the military depôt at Weedon, brought to light many facts tending to show in what manner official mismanagement led to a great waste of public money in obtaining supplies of soldiers' boots and shoes.

The boot and shoe manufacture has till now (1859) been almost wholly a handicraft employment; but the manufacturers of Northampton and Stafford are gradually introducing sewing-machines, to expedite certain departments of the labour. The workmen are bringing all the force of combination and trades' unions to resist this innovation; but the past history of manufactures points clearly to the impossibility of preventing the introduction of such machinery as will expedite the processes or diminish the cost of labour.

Notwithstanding the large number of persons employed in this trade in England, and the abundant supply of leather, there is still a considerable importation of boots and shoes from abroad, chiefly French. These importations, however, are much more largely in boot-fronts than in finished boots and shoes; owing to a considerable difference in the rate of duty. The boots, shoes, goloshes, and boot-fronts imported in the last three years amounted to the following quantities:—

	Boots, Shoes, and Goloshes.	Boot Fronts.	Total.
	Pairs.	Pairs.	Pairs.
1856 . . .	189,835	670,510	860,345
1857 . . .	194,991	551,171	750,162
1858 . . .	165,466	609,596	775,062

BOO'TES (from the Greek *Boûs*, *bos*, "an ox"), one of the old constellations. Its name signifies the *herdsman*; but it is as frequently called *Arctophylax* by the ancients, which means the *guard of the bear*. Aratus calls it by both names.

"Arctophylax, vulgo qui dicitur esse Boötes,"

is the version of Cicero. Both Aratus and Hyginus place ARCTURUS in or under the girdle; but it is usual to draw it between the legs of the figure. Manilius also uses both names. The constellation is connected mythologically with the fables of Arcas, Icarus, Lycaon, and others. The Arabic translators of Ptolemy rendered Boötes by *bellower* or *vociferator*. According to the old figures attached to Hyginus, he is represented as a man with a spear in the right hand (viewed from the back—BAYER, in BIOG. DIV.) and a sickle in the left. The modern figures represent a man with a club in the right hand (viewed in front), and in the left the string which holds the two dogs (Cases Venatici). It would seem to be probable that the Great Bear was originally either an agricultural animal or instrument (an ox, an ass, or a waggon), and Boötes the driver.

The principal stars in Boötes are as follows:—

BORACIC ACID (BO_3), formerly called *Homborg's sedative salt* and *sedative salt of borax*, is a compound of the elementary body boron and oxygen. It exists in considerable quantity in combination with soda in the waters of certain lakes in Thibet and Persia, forming *borax* or the *biborate of soda*. From this salt, which is mentioned under the head of salts of boracic acid, termed *borates*, it is procured by dissolving four parts of it in sixteen parts of boiling water, and adding one part of concentrated sulphuric acid to the filtered solution. Owing to the superior affinity of the sulphuric acid for the soda, sulphate of soda is formed, and the boracic acid separated crystallises as the solution cools: it is to be allowed to drain, to be redissolved in boiling water, and again crystallised to separate the sulphuric acid which adheres to it. In order to purify it entirely from this acid, Berzelius recommends that it should be fused in a platinum crucible, and again dissolved in boiling water and crystallised.

Boracic acid in the uncombined state is found in the hot aqueous and sulphurous vapours that issue from the earth in the volcanic district of Tuscany. It is obtained in the following manner: Round the larger fissures in the sides of a hill basins are dug, usually about five feet deep and fifteen feet in diameter. Into these, called *lagoni* (lagoons), water from a small stream is conducted, and the hot vapours passing through them, leave behind the boracic acid in solution. The hot liquid is then run off into lagoons on a lower level, and finally, after standing some time in reservoirs to deposit suspended impurities, is concentrated in shallow leaden vessels ingeniously heated by flues, through which the hot vapours issuing from some of the fissures are made to pass. On the cooling of the concentrated solution, the boracic acid crystallises out, and when dried, is packed in casks and sent into commerce. It always requires subsequent purification by re-crystallisation.

Boracic acid has the form of small scaly brilliant colourless crystals, which have a greasy feel. This acid is inodorous; its taste is not strong, and scarcely at all acid. It reddens litmus paper but slightly, and turns turmeric paper brown, as the alkalies do. Water at 60° dissolves about 1-26th of its weight of this acid, and boiling water nearly one-third. It contains about forty-four per cent. of water of crystallisation, which is entirely expelled when it is gradually heated to redness in a platinum crucible. If the crystals are suddenly heated, a portion of the acid is carried off by the vapour of the expelled water. When fused boracic acid cools and becomes solid, it splits, and during this operation it is luminous in the dark; the light is probably electric.

When a substance is suspected to contain boracic acid, it should be heated with concentrated sulphuric acid, a small quantity of alcohol added, and the mixture inflamed, when the spirit will burn with a green flame if boracic acid is present. Before applying this test, the absence of copper must be ascertained, as it communicates to flame a similar colouration.

Boracic acid in crystals has a specific gravity of 1.48; when fused it is 1.83. It is soluble in alcohol, and the solution burns with a green flame. Although it acts weakly as an acid upon litmus paper, it decomposes the alkaline carbonates with effervescence, and at a red heat it expels most of the volatile acids from their bases.

Boracic acid is, according to Berzelius, composed of			
3 equivalents oxygen			24.00
1 do. boron			10.91
Equivalent			34.91

Boracic acid is sometimes used in chemical investigations, and was formerly employed in medicine.

Borates are the salts which contain boracic acid: of these the only important one is

Borax, a compound of boracic acid and soda, the correct appellation of which is *biborate of soda*. This salt is imported from the East Indies under the name of *tincal* or *rough borax*. It is supposed to be the substance called by Pliny *chrysocolla*. Geber in the 7th century mentions borax; its nature was pointed out by Geoffroy in 1732 and Baron in 1748. It is brought from Persia, Ceylon, and also from Thibet, from a lake entirely supplied by springs, fifteen days' journey from Teeshoo Lumboo the capital. Tincal as imported is mixed with a fatty matter, which may be separated by acids.

The crystals of tincal are bluish or greenish white, and are sometimes nearly transparent, but more commonly opaque. They are soft and brittle. The primary form is an oblique rhombic prism. Tincal is purified by solution in water and crystallisation, and is then sold as borax.

The greater part of commercial borax is now prepared, both in England and France, by saturating with carbonate of soda the boracic acid imported from Tuscany. This salt is little employed in medicine, but is used extensively in the arts as an ingredient in the glaze of the finer kinds of earthenware, and in chemical investigations as a flux.

The primary form of common borax is an oblique rhombic prism, variously modified; but it has been found by Mr. Payen, that if a saturated solution of borax at 174° be slowly cooled, it deposits crystals when the temperature is above 103°, which are in the form of the regular octohedron. These crystals contain only half as much water as those just described.

Borax has rather an alkaline and sweetish taste, acts like alkalis upon turmeric paper, and is soluble in twelve parts of cold and two of boiling water. It effloresces slowly by exposure to the air, and when two pieces are rubbed together in the dark they become luminous. When moderately heated, borax swells and loses about four-tenths of its weight, and assumes the form of a light porous friable mass, and is called *calcined borax*. When very strongly heated, it melts into a transparent glass. According to Berzelius, it is composed of,

2 equivalents boracic acid	69.80
1 do. soda	31.32
10 do. water	90.00

BORAX. [BORACIC ACID.]

BORDARI, one of the classes of agricultural occupiers of land mentioned in the Domesday Survey, and, with the exception of the villani, the largest. The origin of their name, and the exact nature of their tenure, have been variously interpreted. Lord Coke ('Inst.' lib. i. § i. fol. 5 b. edit. 1628) calls them "boors holding a little house, with some land of husbandry, bigger than a cottage." Nichols, in his 'Introduction to the History of Leicestershire,' p. xlv., considers them as cottagers, taking their name from living on the borders of a village or manor: but this is sufficiently refuted by Domesday itself, where we find them not only mentioned generally among the agricultural occupiers of land, but in one instance as "circa aulam manentes," dwelling near the manor-house; and even residing in some of the larger towns. In two quarters of the town of Huntingdon, at the time of forming the Survey, as well as in King Edward the Confessor's time, there were 116 burgesses, and subordinate to them 100 bordarii, who aided them in the payment of the geld or tax. ('Domesd. Book.' tom. i., fol. 203.) In Norwich there were 420 bordarii: and 20 are mentioned as living in Thetford. ('Ibid.' tom. ii., fol. 116 b. 173.)

Bishop Kennett says, "The bordarii often mentioned in the Domesday Inquisition were distinct from the servi and villani, and seem to be those of a less servile condition, who had a bord or cottage with a small parcel of land allowed to them, on condition they should supply the lord with poultry and eggs, and other small provisions for his board and entertainment." ('Gloss. Paroch. Antiq.') Such also is the interpretation given by Blomfield in his 'History of Norfolk.' Brady says, "they were drudges, and performed vile services, which were reserved by the lord upon a poor little house, and a small parcel of land, and might perhaps be domestic works, such as grinding, threshing, drawing water, cutting wood," &c.

Bord, as Bishop Kennett has already noticed, was a cottage. Bordarii, it should seem, were cottagers merely. In one of the Ely Registers we find bordarii, where the brieve of the same entry in Domesday itself reads *cotarii*. Their condition was probably different on different manors. In some entries in the Domesday Survey, "bordarii arantes" occur. At Evesham, on the abbey demesne, 27 bordarii are described as "servientes curiæ." ('Domesd.' tom. i., fol. 175 b.)

On the demesne appertaining to the castle of Ewias, there were 12 bordarii, who are described as performing personal labour on one day in every week. ('Ibid.' fol. 186.) At St. Edmondsbury in Suffolk, the abbot had 118 homagers, and under them 52 bordarii. The total number of bordarii noticed in the different counties of England in Domesday Book is 82,634.

(Ellis's *General Introd. to Domesday Book*; Heywood's *Dissert. upon the Ranks of the People under the Anglo-Saxon Governments*.)

BORDER WARRANT is a writ issued by the sheriffs of the Scottish border counties, to apprehend a person domiciled in England who has incurred debt in Scotland, if he should happen to be in the sheriffs' jurisdiction. It is given on oath being made to the debt, and to the party's domicile. The principle of arrest on mesne process was never sanctioned in Scotland, farther than to the extent of apprehending debtors about to escape from the country (*in meditatione fugæ*) until they should pay their debt or find security for it, and the border warrants, which are in practice disused, are a part of the system.

BORE, less commonly BOAR, a phenomenon which occurs in some rivers, near their mouth at spring tides. When the tide enters the river, the waters suddenly rise to a great height, in some rivers many feet above the surface of the stream, and rush with tremendous noise against the current for a considerable distance. Sometimes the waters do not subside till they have almost reached the limit of tide-water. As this swell does not occur in all rivers where there is a tide, it is evident that it must be caused by some conformation of the banks or bed of the river,

or by both combined. It seems to be necessary, in order that there should be a bore, that the river should fall into an estuary, that this estuary be subject to high tides, and that it contract gradually; and lastly that the river also narrows by degrees. The rise of the sea at spring tides pushes a great volume of water into the wide entrance of the estuary, where it accumulates, not being able to flow off quickly enough into the narrower part. The tide therefore enters with the greater force the narrower the estuary becomes, and when it reaches the mouth of the river, the swell has already obtained a considerable height above the descending stream, and rushes on like a torrent.

In England the bore is observed in some rivers, more especially in the Severn, as particularly described below, in which it has a face 9 feet high, the Trent (Stark's 'Gainsborough'), the Wye, in the Solway Frith, and probably in other rivers and estuaries also, in which the water rises suddenly a few feet, and then rushes on against the current of the river. The bore is called in some parts of England, for instance in the Trent and Severn, the Eagre or Hygre. (Gibson's 'Camden,' i. 268; Stark.) This phenomenon takes place near Bordeaux, in the Garonne, and also in its affluent the Dordogne, and is called *le Mascaret*.

Some of the most remarkable bores hitherto described are those of the Ganges and Brahmapootra. In the Hoogly branch of the Ganges the bore is so quick, that it takes only four hours in travelling from Fultah to Nia-serai, above Hoogly town, a distance of nearly 70 miles. At Calcutta it sometimes causes an instantaneous rise of 5 feet, which would occasion great damage among the smaller vessels, if it did not run along one bank only, so that the barges, on hearing the noise which precedes it, can be safely brought to the other side of the river, or to the middle, where the swell is indeed considerable, but not so sudden as to endanger vessels which are skilfully managed. In the channels between the islands at the mouth of the Megna or Brahmapootra, the height of the bore is said to exceed 12 feet, and it is so terrific in its appearances, and so dangerous in its consequences, that no boat will venture to navigate there at spring-tide; but it does not ascend to any great distance in this river, which is probably owing to the great width of the channel of the Megna. Dr. Joseph D. Hooker, F.R.S., in his 'Himalayan Journals' (vol. ii. p. 343), has given a picturesque description of the manner in which his passage, of about 100 miles, from Noacolly on the east bank of the Megna, to Chittagong at its most eastern mouth, was affected by the bore of that river; from which the following particulars are derived: "The great object in this navigation is to keep afloat, and to make progress towards the top of the tide and during its flood, and to ground during the ebb in creeks where the bore (tidal wave) is not violent; for where the channels are broad and open, the height and force of this wave rolls the largest coasting craft over, and swamps them." The ebb, at the mouth of the Fenny, a tributary of the Megna, sometimes retires twenty miles from high-water mark. After this, of course, no water is either to be seen or heard; nothing is visible but glistening oozy mud, except the bleak level surfaces of the islands; until, on the return of the tide, in popular language, a white line is seen on the low black horizon, which is the bore, advancing at the rate of five miles an hour, with a hollow and harsh roar, bearing back the mud that was following the ebb.

It will be seen that there are some unexplained inconsistencies in the several accounts of the bore as occurring in this river, the Ganges, and others, with regard to the comparative safety of vessels in the central streams and near or upon the banks. It is evident, also, that as there is every variety in rivers, with respect to the dimensions of the tidal stream and the rate of contraction of the banks, so there is a corresponding variety in their bores, from the narrow rushing torrent of comparatively great altitude, emphatically the *bore*, to the slightly elevated and accelerated quiet tide-wave. In the case of the Megna, described by Dr. Hooker, we have an intermediate variety.

The bore in the Gulf of Cambay and its tributaries is exceedingly high and rapid, in consequence of which, and of the currents in the gulf, its navigation is dangerous. The phenomenon observed in the mouths of the Indus must be of the same kind. Burnes remarks ('Journal of R. Geog. Soc. Lond.,' vol. iii.) that "the tides rise in the mouths of the Indus about 9 feet at full moon; and flow and ebb with great violence, particularly near the sea, where they flood and abandon the banks with equal and incredible velocity. It is dangerous to drop the anchor unless at low water, as the channel is frequently obscured, and the vessel may be left dry. The tides are only perceptible 75 miles from the sea." The ships of Alexander experienced these dangerous tides in the Indus, and his historian, Arrian, is the first who has described them. ('Anab.' vi. 19.)

The tides in the bay of Fundy are perhaps the highest in the world, the spring tides in some places rising 60 or 70 feet perpendicular; and the bore in the creek of Fundy is higher than in the Severn. On the N. coast of Brazil, especially on the shores of the provinces Parà and Maranhão, a similar phenomenon is observed in some rivers, and in the channel which extends between the coast and a series of islands from Cape Norte to the mouth of the river Macappà. This phenomenon, which is called by the Indians *pororoca*, is particularly strong in the Amazonas, at the junction of the Araguari river, and in the rivers Guama and Capim near Parà, and also in the river Meary in Maranhão. The description of the *pororoca* does not differ materially from that of the bore of the rivers in India, except that it rises to from 12 to 16

feet, and forms three or even four swells, which follow in rapid succession. [AMAZONAS, in GEOG. DIV.] It is also said that some parts of these rivers being obstructed by shoals, the pororoca is only observable on these shoals, and that it disappears in deep water, for which reason the barges are moored in these parts, where they are only exposed to a strong agitation of the waters. (Rennell's 'Hindoostan'; Ayre's 'Corografia Brasilica'; and Eschwege's 'Brasilien'.)

The preceding statements comprise the principal facts embraced in the local history of this phenomenon, as described by various observers, and at various periods; but recent investigations, by which the theory of the tides and of waves has been at once corrected and worked out into detail, enable us to add a more explicit view of the nature of the bore, which has become a subject of great theoretical interest.

The Rev. Dr. Whewell has shown that we may consider the banks of a river as a portion of the sea-shore in which there is a point of convergence of tides; and the magnitude of the tides will be increased by this convergence. If we consider the production of these very high tides of convergence as a mechanical question, they may be accounted for by what is called "the principle of the conservation of force." When any quantity of matter is in motion, its motion is capable of carrying every particle of the mass to the height from which it must have fallen to acquire its velocity; but if the motion be employed in raising a smaller quantity of matter, it is capable of raising it to a height proportionally greater. In channels which narrow considerably, the quantity of water raised in the narrow part is less than in the wider, and thus the rise in such cases is greater. The tide being thus made to rise greatly by the contraction of its channel, the part of the water so affected may be abruptly terminated on the inland side, the depth and quantity of water on that side not allowing the surface there to be immediately raised by means of transmitted pressure. A tide-wave thus rendered abrupt, is called a *bore*, and has a close analogy with the waves which curl over and break on a shelving shore. It would appear, indeed, from the researches of Scott Russell, that such waves present us with the limit of the phenomenon. The bore itself, as we have seen, occurs in many places in considerable magnitude, appearing to travel with great rapidity, though moving slower, in fact, than the tide-wave under any other circumstances; and producing great noise by the large amount of intestine motion of its particles.

One of the results of Mr. John Scott Russell's experimental determination of the nature of waves, just cited, is the identification (which had been anticipated by Dr. Whewell) of the tide-wave with that which he has denominated the great primary wave of translation [WAVE], it being the only wave of the ocean belonging to that order. The tide appears to be a compound wave, one elementary wave bringing the first part of flood-tide, another the high water, and so on; these move with different velocities according to the depth. On approaching shallow shores, the anterior tide-waves move more slowly in the shallow water, while the posterior waves moving more rapidly, diminish the distance between successive waves. The tide-wave thus becomes dislocated, its anterior surface rising more rapidly, and its posterior surface descending more slowly than in deep water. According to the principles thus established by Mr. Scott Russell, "a tidal bore is formed when the water is so shallow that the first waves of flood tide move with a velocity so much less than that due to the succeeding part of the tidal-wave, as to be overtaken by the subsequent waves, or wherever the tide rises so rapidly, and the water on the shore or in the river is so shallow, that the height of the first wave of the tide is greater than the depth of the fluid at that place. Hence in deep water vessels are safe from the waves of rivers which injure those on the shore." This last consequence is indicated in the accounts of the local phenomena. (Whewell, 'Essay towards a First Approximation to a Map of Co-tidal Lines,' Phil. Trans., 1833, pp. 203—205; Scott Russell, 'Report on Waves,' Rep. of Seventh Meeting of British Association, 1837, pp. 426, 427.) In some observations made in the Section of Mechanical Science of the same meeting of the Association, Mr. Russell applied his theory of the tide-wave to the improvement of rivers by the removal of the bore, which he stated, "is principally found in rivers and places of rivers where the level of the bed is situated near the level of the mid-tide. This wave changes its form as it approaches a shallow coast, the top being then accelerated, and breaks in a surge when it gets to water of less depth than itself. Supposing, then, that the tide has a bore three feet high, the water being three feet deep, by deepening the channel you remove the bore, and this is the only effectual remedy." ('Athenæum,' 1837, p. 704.)

On reviewing the present state of knowledge and theory on the subject of the bore, as a topical condition of the tidal-wave, it is manifest that science still requires an exact investigation of particular cases, as occurring in localities differently circumstanced, giving precise measures, both of the heights and velocities of the wave, and an application of the theory to explain the varying particulars of the phenomenon; together with an explicit verification of such portions of it as, though in the highest degree probable, must still be regarded as hypothetical.

This is confirmed by the following comprehensive description of the bore by the Astronomer-royal, Mr. Airy, which may be regarded as a commentary both on the local accounts and the theoretical explanations given above. Connected with the rapid rise when the tide is very large in proportion to the depth of the water, "is the bore; a phenomenon

on which, we believe," Mr. Airy remarks, "some misconception prevails. We believe that the following description of its cause and appearance will be found correct. It is necessary for its formation that there be a very large tide rising with great rapidity (thus at Newnham [on the Severn], where the water rises 18 feet in an hour and a-half, the bore is considerable). It is necessary, also, that the channel of the river be bordered with a great extent of flat sands near to the level of low water. These circumstances hold in the Severn, the Seine, the Amazonas, the bays at the head of the Bay of Fundy (Chignecto Bay, and the Bay of Mines), and other places where the bore is remarkable: the second does not hold in the Thames; and, in consequence, that river has no bore. When the rise of the tide begins, the surface of the water is disturbed in mid-channel, so as to distort reflection; but the water is not broken, it is merely like a common wave. This point (which we state from our own observation) is fully confirmed by De la Condamine's account of the bore in the Amazonas, and by the practice in the Hoogly river (near Calcutta), and other places subject to a bore, of rowing boats, &c., into the middle of the channel on the approach of the bore, in order to place them out of danger. But as this rapid rise elevates the surface suddenly above the level of the flat sands, the water immediately rushes over them with great velocity, and with a broken front, making a great noise. And this is the whole of the bore. It is, however, a majestic phenomenon, especially when witnessed from a station which commands the river for several miles above and below (we may particularly mention Newnham churchyard, on the Severn), and at an hour when other sounds are stilled. The rise of the water continues, after the bore has passed, with unabated rapidity as far as can be seen by general observation, and the tidal current flows rapidly up the river, which is now quite full. At last its rapidity of rise diminishes, and at 90 minutes after the bore, at the place which we have mentioned, it begins to drop, the current still flowing up. About 15 minutes after the beginning of the drop, a singular line of ripple (of which we can give no further explanation) is seen, stretching across the whole river, and moving very slowly downwards. This appears to be the place at which the ascending current and the descending current meet; for, as soon as it has passed, the water is seen to be running slowly downwards, and in a very short time it is running with a speed which is scarcely to be seen under any other circumstances of any river, except perhaps some of the largest rapids. The remarkable point attending this last phenomenon is, that the phase of change of current moves down the river. In every other instance, the phases, whether of high water, of low water, or of change of current, move upwards; although that of low water moves upwards much more slowly than that of high water. It would seem here that one of the velocities has actually changed its sign." ('Tides and Waves,' Ency. Met., 514.)

In a paper on the mathematical theory of sound, by the Rev. S. Earnshaw, read before the Royal Society on the 6th of January last (1859), the phenomenon of the bore is investigated in its most simple form, but in harmony with the more complicated cases of the waves of water occurring in nature, and noticed in this article: "It is shown that all the parts of a wave [in this case in a uniform elastic medium] do not travel at the same rate; a circumstance which leads to the formation of a bore in the front of the wave." The principle is then applied to account for several acoustic phenomena, previously unexplained, such as double reports of fire-arms heard at a great distance, and the outrunning of one sound by another, observed by Capt. Parry. ('Proceedings of the Royal Society,' vol. ix. p. 591.) It does not appear that the analogous condition of the undulations of the ether, giving rise to optical phenomena, has been investigated, or even recognised. As the production of the bore results from circumstances foreign and external to the intrinsic nature of waves, it would seem to require for its discovery an artificially constructed system of crystallised bodies, having different refractive and polarising powers for light; though it is not improbable that systems of such a kind as would produce the phenomena may exist in nature.

On the subject of the origin and etymology of *bore* we have no express information. It has been conjectured to be an Indian word, but for this there is no foundation; and a more probable derivation is from the Anglo-Saxon, in the older sense of the English word *to bore*, signifying to penetrate by a powerful forward action. When called the *Boar*, and the *Boar's head*, as is also the case, a comparison with the impetuous rushing career of that animal is suggested, in which the word may have originated. It may be doubted, however, whether most, if not all, the terms designating this phenomenon, are not imitative of the sounds which it produces, and have been involuntarily suggested by them, as occurring in varying intensity and order. The prolonged sound of *bore*, and its French form *barre*, and the Brazilian *pororoca*, are strikingly of this character, which may possibly be attributable to *Hygre* also, given without etymon in our archaic dictionaries; but this is evidently the same word with the Dutch *agger*, denoting the kindred phenomenon of double high-water. Some of these terms may subsequently have been employed in conformity with a supposed etymology, and if such has been the case, as in other cases of the confluence of meaning in philology, further inquiry would be hopeless.

BORING INSTRUMENTS. Whether the vertical cavity for an artesian well is made, or the cavity of a cannon formed, or the cavity

of a cylinder or barrel perfected, or a hole simply made in wood—the term *boring* is equally applied to all these operations.

Cannon are usually cast solid, and bored by machinery; and in an accommodated sense the term is applied to the similar operations by which musket-barrels, the cylinders of steam-engines, and other articles which are originally made hollow, have their inner surface turned to a perfectly smooth surface and cylindrical shape. The boring instruments of the carpenter consist of *awls*, which are put into soft wood, with a rotatory motion, without removing or bringing away its substance; *gimlets* and *augers*, which are supplied with cutting edges, and are partially hollowed, to allow of the escape from the hole of the detached particles of wood; and *bits* of various kinds, which also remove the wood, and are applied with greater power and precision by means of a crank-shaped instrument called a *brace*. Small holes in metals are usually bored with *drills*, which are formed with scraping rather than cutting edges, and are used either in a brace, a drill-stock capable of imparting an alternating rotatory motion by means of a bow worked by hand, or some other contrivance, or in a lathe. Boring machines of the lathe character are too various and complex to be described here. Suffice it to say, that the perfection to which they have been brought, has rendered most essential service to science and manufactures, and removed one of the greatest difficulties experienced by early improvers of the steam-engine.

The boring of Artesian wells is performed with various kinds of chisels or *jumpers*, augers, and instruments suitable for extracting the detached fragments, attached to the lower end of an iron rod formed of many lengths screwed into one another; these instruments are either turned round, or jumped up and down, or worked with a combination of these two motions by suitable mechanism, the kind of tool employed, and the mode of working, being varied from time to time as the several strata are met with.

Beart's boring tools, patented in 1844, are intended to be used in circumstances where the hole made by the borer can be kept constantly full of water. The borer itself is attached to a hollow tube instead of a solid rod, and acts as one leg of a siphon; the other leg being an excavated channel prepared for the purpose, and kept full of water. The arrangement of the several parts is such, that as fast as the fragments of rock or soil are loosened by the borer, they are drawn up with the water by which they become saturated, through the tube which forms the stem or vertical rod of the borer: this, at least, is the theory on which the inventor has founded his patent.

At the meeting of the British Association in 1846, Mr. Vignolles communicated an account of a method of boring Artesian wells, invented by M. Fauvel of Perpignan. M. Fauvel had observed that in several cases of success in boring for water with solid iron rods, so soon as the spring was tapped all the triturated particles were brought up without the use of the auger. He inferred that if the boring could be effected by a hollow tube about two inches less in diameter than the width of the auger, communicating with an injecting force-pump by a flexible tube from the surface, a result would follow similar to that which resulted from the natural power of the rising column of water. Having tested the hypothesis, he found that the well could be bored in much less time than by the former method. The plan has since been largely adopted, in some cases to very great depths.

An attempt was made by Mr. Gard, of Calstock, in 1848, to produce an improved boring-machine, to effect in another way the objects intended by Mr. Beart in England, and M. Fauvel in France. His boring-machine consists of a hollow cylinder, to the bottom of which the boring-bit is attached in a peculiar way; and as the rock or earth is bored, the fragments force themselves up into the cylinder, where they are retained by a valve. The cylinder does not reach to the top of the bore, but requires to be raised when full, in order that it may be emptied; it, however, will contain so large a quantity, that the necessity of raising it will occur much less frequently than under the usual system. Instead of joining successive lengths of rod to the boring tool, the latter is raised and lowered by a chain.

At a meeting of the Cornwall Polytechnic Society, a few years ago, Mr. Prideaux proposed the adoption of a chemical means of facilitating the process of boring. He found that a stream of hydro-oxygen gas applied to a piece of granite stone produced heat; and that on the application of cold water the stone became soft, and yielded to the tool. Oxygen might be superseded by common air from a pair of double bellows; and common coal-gas might be used instead of hydrogen.

A very instructive illustration of the apparatus employed in well-boring may be studied at the Museum of Economic Geology.

BORNEENE. [CAMPHOR.]

BORNEOL. [CAMPHOR.]

BORNEO-CAMPHOR. [CAMPHOR.]

BOROFLUORIC ACID. [FLUOBORIC ACID.]

BORON (B), an elementary body, and one of the constituents of boracic acid, oxygen being the other. This substance was first obtained by Davy in 1807, and he procured it by exposing slightly moistened boracic acid, placed between two surfaces of platinum, to the action of a Voltaic battery; a dark-coloured substance separated on the negative plate, to which he gave first the name of *boracium*, supposing it would be found to be metallic; but having afterwards ascertained it to be more analogous to carbon than to any other substance, he called it

ARTS AND SCI. DIV. VOL. II.

boron. In this way however little boron was obtained, and its properties were imperfectly examined till 1808, when Gay Lussac and Thenard procured it in larger quantity by heating boracic acid with potassium in a copper tube; by this metal the oxygen was separated from the boron, potash was formed, and boron developed; and the residue of the operation being washed first with water, and then with dilute hydrochloric acid, the boron remains. It is more economically obtained by decomposing an alkaline borofluoride by potassium; for this purpose liquid hydrofluoric acid is to be saturated with boracic acid, and the solution neutralised by carbonate of potash; the salt precipitated is to be well washed with cold water, and dried at nearly a red heat; it is then mixed with an equal weight of potassium, and the mixture heated to redness in a covered iron crucible; the residual mass will be found to consist of boron mixed with fluoride of potassium; the fluoride is dissolved out from the boron by washing with water containing a little chloride of ammonium. The decomposition that takes place is expressed in the following equation:—

Boron is a powder of a deep brown colour with a shade of green; and when it has been heated *in vacuo* or in gases which contain no oxygen, it is insoluble in water; and is not dissolved by alcohol, ether, or oils, whether hot or cold. It is devoid of smell and taste. It is not altered by exposure to the air or to oxygen gas at the usual temperatures; but when heated to about 600° it absorbs oxygen, and, burning with considerable brilliancy, is converted into boracic acid; a portion however of the boron is so enveloped by the acid formed, that it is impossible to burn the whole of a given quantity of boron at one operation.

Boron does not decompose water at a boiling temperature. Its density when recently prepared is 1.183, but when it has been exposed to a strong heat in close vessels its density is increased to 1.844, and it suffers no other change, being neither fused nor volatilised. It may be melted however by the heat of a powerful galvanic battery. It is a non-conductor of electricity; the alkalis and acids produce no effect upon it, except the nitric, which it decomposes, and the boron, by acquiring oxygen, is converted into boracic acid. It has a greater affinity for oxygen than carbon, setting the latter element free when it is fused with carbonate of potash.

Prepared by the above method, boron is quite amorphous. According to Professor Wöhler and M. Deville it may be obtained in the crystalline condition by fusing boracic acid with 80 per cent. of the metal aluminium in a powerful furnace. The boracic acid is reduced by a portion of the aluminium, the remainder dissolving the boron, which separates out on cooling in transparent garnet-red crystals of high lustre and refractive power.

Crystallised boron is exceedingly hard. It scratches corundum and even sapphire with ease. A crystal may be crushed with a diamond, but the latter is marked and slightly damaged by the operation. It cannot be fused alone by any known means; it resists the action of oxygen at a far higher temperature than the amorphous variety, even nitrate of potash being without action upon it at a red heat.

Graphitic boron is the name given to that form of the element obtained when borofluoride of potassium is decomposed by aluminium at a high temperature with a flux of the chlorides of potassium and sodium in equivalent proportions. It may be quite freed from aluminium by digesting in hydrochloric acid. It presents a close resemblance to ordinary graphite,—that modification of carbon intermediate between charcoal and diamond. Its appearance is also very similar to graphitic silicon, thus establishing the intimate and interesting physical analogy that exists between these three elements.

Boron combines with various elementary bodies, forming with the metals compounds which are termed *borides*.

Hydrogen and Boron. It appears that, under peculiar circumstances, hydrogen is capable of dissolving a small portion of boron; but no definite compound to which the term boride of hydrogen could be applied is known.

Oxygen and Boron unite, and only in one proportion; the compound is described under BORACIC ACID.

Boron and Nitrogen. Boron decomposes nitric oxide at a red heat, boracic acid and nitride of boron (BN) being formed. The latter is a white, light, amorphous powder. Heated with caustic potash, it yields ammonia, borate of the alkali being at the same time produced.

Boron and Sulphur form sulphide of boron (BS₃), but the compound possesses no interest.

Boron and Chlorine unite with considerable energy when the former is heated to redness and plunged into an atmosphere of the latter gas.

Boron and Fluorine combine. [FLUOBORIC ACID.]

BOROUGH-ENGLISH is a customary descent of lands or tenements, whereby, in all places where this custom holds, lands and tenements descend to the youngest son; or if the owner of land have no issue, then to the youngest brother; as in Edmonton, some parts of Richmond, and other places: and the reason of this custom, says Littleton, is, for that the youngest son is presumed in law to be least able to shift for himself.

Blackstone, who divides the common law into three divisions, treats of Borough-English under the second division, namely:—"Particular customs, which for the most part affect only the inhabitants of particular districts." In the first volume of the 'Commentaries' he gives a definition of the term similar to that contained in Dr. Cowell's Dictionary; and in the second volume he recurs to it, and observes:—"Other authors have indeed given a much stronger reason for this custom, as if the lord of the fee had anciently a right to break the seventh commandment with his tenant's wife on her wedding-night; and that therefore the tenement descended not to the eldest but the youngest son, who was more certainly the offspring of the tenant." Blackstone, however, states that he cannot learn that this right was exercised in England, although it certainly was in Scotland, until abolished by Malcolm III., and in some parts of France; and even if it were, the reason, as it regards the youngest son *only*, is obviously absurd. "Perhaps (he adds) a more rational account than either may be fetched (though at a sufficient distance) from the practice of the Tartars; among whom, according to Father Duhalde, this custom of descent to the youngest son also prevails. That nation is composed totally of shepherds and herdsmen, and the elder sons, as soon as they are capable of leading a pastoral life, migrate from their fathers with a certain allotment of cattle, and go to seek a new habitation. The youngest son, therefore, who continues latest with the father, is naturally the heir of his house, the rest being already provided for. So that possibly this custom, wherever it prevails, may be the remnant of that pastoral state of our British and German ancestors which Cæsar and Tacitus describe." But it is unnecessary to go so far for the origin of a custom which the name itself and other circumstances show to be of English origin.

BOROUGH, OF GREAT BRITAIN AND IRELAND. [MUNICIPAL CORPORATIONS; COMMONS, HOUSE OF.]

BOSTANJI, from *bostan*, a garden. The class of men who bear this name, who now perform a curious variety of functions, and whose head or chief (Bostanji-Bashi) is one of the grand dignitaries of the Turkish empire, seem originally to have been nothing more than the sultan's gardeners, attached to the imperial residence or seraglio of Constantinople, and were constituted guardians of the seraglio by Soliman the Great. They still work as gardeners in the sultan's pleasure-grounds of Constantinople and on the Bosphorus, but the more conspicuous of their duties are, to mount guard in the seraglio, to row the sultan's barge, to row the caïques of all the officers of the palace, to follow those great men, on foot, when they ride on business through the city, and to attend to the execution of the numerous orders of the bostanji-bashi. They were aggregated with the janissaries, with whom they formerly did military duty in the field, but the bostanjis were not suppressed at the sanguinary dissolution of that turbulent militia, although their number has been considerably decreased. When the Ottoman Court was in its splendour, the bostanji corps amounted to 5000 men, who were divided into *ortas*, or companies, like the janissaries. The distinctive part of their costume was an enormous bonnet, or *caouk*, made of scarlet cloth, and in war they were increased to 12,000. At present they do not exceed 600.

The bostanji-bashi, who has the rank of a pasha, is governor of the seraglio and the other imperial residences. He is inspector-general of the woods and forests in the neighbourhood of Constantinople. The shores of the Bosphorus and the Sea of Marmora, from the mouth of the Black Sea to the Straits of the Dardanelles, are under his jurisdiction, and formerly no person whatsoever could build or even repair a house on those coasts without his permission. For this licence fees were exacted, which were generally fixed in the most arbitrary manner. Whenever the sultan makes an excursion by water (and in the fine seasons he rarely travels in any other way) the bostanji-bashi stands or sits behind him, and steers the magnificent barge, which is rowed by the bostanjis. This brings him into frequent contact and conversation with the sovereign, who never appoints any but personal favourites to the post. At court the bostanji-bashi is almost as great a man as the *kislaragha* (chief of the black eunuchs) or the *selictar* (the sultan's sword-bearer). He used also to exercise the functions of provost-master-general, presiding at the bow-stringing of the Turkish grandees when the execution took place within the walls of the seraglio, and superintending the tortures applied in the prison of that palace, to force from obstinate ministers and government functionaries the confession of their guilt and disclosure of their property, which latter was always confiscated to the sultan.

Except when at the helm of the imperial barge, the bostanji-bashi used rarely to be seen abroad by day-light; "no doubt," says D'Ohsson, with much naïveté, "on account of the sensation produced by the presence of the supreme minister of executions."

Another very lucrative duty attached to this composite office was the *inspection* of the trade in wine, and lime, or mortar for building, carried on in the capital and its vicinity. Of late years, however, since Sultan Mahmoud has become a reformer, both the money-getting branches of the office, and the more horrible functions of the bostanji-bashi, have been considerably abridged; and in time we may hope to see him as harmless a character as the commander of a royal yacht or a court chamberlain in Christendom.

BOSWELLIA THURIFERA. A native of the mountainous parts of India; yields the gum-resin (improperly termed gum) olibanum, the

frankincense or *thus* of the ancients. This substance was long supposed to be obtained from various species of *Juniperus* of the family of the *Coniferae*. Some persons are still of opinion that the Arabian olibanum is derived from a juniperus; which, independent of our positive knowledge of the source of the Indian olibanum, is very improbable, for as Nees von Esenbeck justly remarks, the *Coniferae* yield only pure resins, or resins consisting of resin, volatile oil, and sub-resins, but in no case any gum-resins. Indeed, if the Arabian olibanum be not obtained from a *Boswellia*, it is most probably yielded by a *Balsamodendron*: (*Kafal*? *Försk.* possibly only a variety of *B. Katak.* *Försk.*) at least the wood of this tree is used to burn as a perfume in the mosques. There is now scarcely a doubt but that it is the produce of *Boswellia floribunda* of Bennet, the *Plöslea floribunda* of Endlicher. Mr. Johnstone ('Philos. Trans.' for 1839, pp. 304, 305) asserts that there are two distinct gum-resins in olibanum.

The chemical analysis gives very different results, according to the age of the piece examined. Sir William O'Shaughnessy analysed a fine fresh specimen in India, which yielded resin, 37, volatile oil, 28 parts; gum, 4, gluten, 11 per cent.: while Bracount, analysing older specimens in Europe, obtained only volatile oil, 8; resin, 56; gum, 30; gum-like matter, loss, &c., 6; showing the gradual conversion of the volatile oil into resin, and the superior quality of fresh specimens.

The odour of olibanum is faint and peculiar, but pleasantly balsamic, which is increased by heat, and when inflamed it burns with a steady, clear light, which is not easily extinguished, diffusing a most fragrant smoke. It leaves behind it a black ash. The taste is balsamic, slightly acrid and bitter. Being a gum-resin, it is not perfectly soluble either in water or alcohol; with the former it forms a milky fluid. It consists of gum-resin and volatile oil: the latter principle has the odour of oil of lemon. The Indian olibanum is not often adulterated, but an inferior or the Arabian kind is often substituted. The latter is frequently intermixed with mastic, gum-sandarac, or Burgundy pitch: when there is much of this last article, it may be discovered by the greater solubility in alcohol.

Olibanum is now seldom used in medicine: it possesses the properties common to balsamic substances, and may, in the absence of inflammatory symptoms, or after appropriate antiphlogistic treatment, be used as an expectorant. It is more useful externally as a rubefacient and antispasmodic, especially applied as a plaster over the stomach in some cases of cramp or spasm of that organ. It is however principally employed to burn as incense in Roman Catholic churches.

BOTTLE PAPERS. A term which of late years has been applied to the inclosures frequently found in bottles discovered floating on the sea, or which have been found cast by the tide upon a shore. It is customary for navigators to endeavour to ascertain the sets of the ocean currents by writing the ship's name, the latitude, longitude, date, &c. on slips of paper, and sealing them securely in wine or other bottles, which when thrown overboard are often drifted into very distant localities, whereby valuable comparisons have already assisted the hydrographer. Some very interesting and important facts connected with bottle papers, and a bottle paper chart may be seen in the 'Nautical Magazine' of September 1857, and in other numbers, as published monthly under the Hydrographic Department of the Admiralty.

BOTTLES, GLASS. The manufacture of these articles is described under GLASS. Considered as a source of revenue, glass-bottles, in common with other descriptions of glass-ware, were first subjected to a duty by the 6 & 7 Will. and Mary; but the duty then imposed, after undergoing various modifications, was repealed four years after by an act, the preamble of which recited that it was "found by experience that the duties on glass and glass-ware are very vexatious and troublesome in the levying and collecting the same, and of small advantage to the Crown, and should the same be continued would lessen the duty on coals much more than the said duties on glass-ware would amount to, would hinder the employing great numbers of poor, and endanger the loss of so beneficial a manufacture to this kingdom." The experience thus recorded led to the exemption of glass-bottles from duty for about half a century; but the exigencies of the State induced the government to reimpose the duty in 1746. The duty, so reimposed, was continued until quite recent times, varied occasionally in ratio.

Glass bottles are now made to such an enormous extent in this country, that after supplying the home demand, a quantity is exported so large as to furnish the following figures:—

	Weight.	Declared Value.
1856 . . .	526,813 cwts.	£291,632
1857 . . .	577,209 "	319,480
1858 . . .	542,810 "	301,188

These, it must be observed, are designated "common bottles," made of cheap materials, and do not include flint-glass bottles.

BOTTOM HEAT, a term in horticulture expressive of an artificial temperature communicated by means of fermenting matter or otherwise to the soil in which plants grow. It is usually obtained either by leaves, or tan, or fresh stable-litter, thrown into a heap, and enclosed within the walls of a brick pit, the surface of which is covered with soil. The object of the cultivator is by such means to prevent the temperature of the soil from becoming less than 60° Fahr. or more than 90°. The plants to which this kind of temperature is applied

are pine-apples, melons, cucumbers, &c., and certain tropical plants cultivated in stoves.

It is probable that the operation took its rise at a time when it was extremely difficult to procure an equable temperature of the atmosphere by other means; and when, if the heat of smoke in flues was employed, it had the effect of drying the air in which plants were cultivated till it was unfit for their respiration. Fermenting matter, the temperature of which was prolonged and steady, had in addition the great but hardly appreciated convenience, of keeping the air also gently moistened; and in this the greatest advantage was found to result. Physiologists tell us that although the principal part of the water of vegetation is derived from the soil, yet plants are exceedingly benefited by the presence of a certain quantity of vapour in the circumambient air, because it not only prevents a too rapid evaporation from the leaves, but is to a considerable extent absorbed by the young epidermis.

By modern improvements it has been found practicable to maintain the atmosphere of a hothouse in any required state of humidity or temperature; and when steam or hot water are made use of, this may be carried to a great nicety, and the means of doing this are within the reach of most gardeners. One would therefore have thought that the system of bottom-heat would be abandoned. So far however is this from being the case that it is still much employed, and in combination with those additional powers which were originally intended to supersede it.

It is an axiom in horticulture that the more closely we approach nature in our management of plants the more certain are we to succeed in our attempts at cultivation. It therefore becomes an important question whether bottom-heat has any existence in nature; some persons imagine that it can only be looked for in equinoctial climates. But the data that we possess upon this subject, although not very precise, are sufficient to enable us to answer in the affirmative, as has been already stated under the article BARK-BED, to which the reader is referred. Those who hold a different opinion evidently confound cases in which the earth is heated and dried up, with those in which it is merely warmed and maintained in the necessary state of dampness.

BOTTOMRY, BOTTOMREE, or BUMMAREE, is a term derived into the English maritime law from the Dutch or Low German. In Dutch the term is *Bomerie* or *Bodemery*, and in German *Bodmerei*. It is said to be originally derived from *Boden* or *Bodem*, which in Low German and Dutch formerly signified the bottom or keel of a ship; and according to a common process in language, the part being applied to the whole, also denoted the ship itself. The same word, differently spelt, has been used in a similar manner in the English language; the expression *bottom* having been commonly used to signify a ship, previously to the 17th century, and being at the present day well known in that sense as a mercantile phrase. Thus it is a familiar mode of expression among merchants to speak of "shipping goods in foreign bottoms."

The contract of bottomry in maritime law, is a pledge of the ship as a security for the repayment of money advanced to an owner or master, for the purpose of enabling him to carry on the voyage. It is understood in this contract, which is usually expressed in the form of a bond, called a Bottomry Bond, that if the ship be lost on the voyage, the lender loses the whole of his money; but if the ship and tackle reach the destined port, they become immediately liable for the money lent, and also the premium or interest stipulated to be paid upon the loan. No objection could be made, while the usury laws were in force, on the ground of usury, though the stipulated premium exceeded the legal rate of interest, because the lender was liable to the casualties of the voyage, and was not to receive his money again at all events. In France the contract of bottomry is called *Contrat à la grosse*, and in Italy *Cambio maritimo*, and is subject to different regulations by the respective maritime laws of those countries. The German *Bodmerei* differs in many of its incidents from Bottomry in this country.

In taking up money upon Bottomry, the loan is made upon the security of the ship alone; but when the advance is made upon the goods and merchandise or lading, then the borrower only is personally liable for the money, and is said to take up money at *respondentia*. In this distinction as to the subject matter of the security, consists the only difference between Bottomry and Respondentia; the rules of English maritime law being equally applicable to both.

The practice of lending money on ships was common in Athens, and in other Greek commercial towns. Money thus lent was sometimes called (*ναυτικά χρήματα*) ship-money. Demosthenes (*I. Against Aphobus*), in making a statement of the property left him by his father, enumerates seventy minæ lent on bottomry. If the ship and cargo were lost the lender could not recover his principal or interest; which stipulation was often expressly made in the (*συγγραφή*) bond. (*Demosthenes against Phormion, and against Dionysodorus, c. 6. 10.*) The nature of the bottomry contract is shown in the Oration of Demosthenes against Dionysodorus: 3000 drachmæ were lent on a ship, on condition of her sailing to Egypt and returning to Athens; the money was lent on the double voyage, and the borrower contracted in writing to return direct to Athens, and not dispose of his cargo of Egyptian grain at any other place. He violated his contract by selling his cargo at Rhodes, having been advised by his partner at Athens that the price of grain had fallen in that city since the departure of the vessel. The plaintiff

sought to recover principal and interest, of which the borrower attempted to defraud him; damages also were claimed, conformably to the terms of the bond. As neither principal nor interest could be demanded if the vessel were lost, it was a common plea on the part of the borrower that the ship was wrecked.

Money was also lent, under the name of *pecunia trajecticia*, on ships among the Romans, and regulated by various legal provisions. The rate of interest was not limited by law, as in the case of other loans, for the lender ran the risk of losing all if the ship was wrecked; but this extraordinary rate of interest was only due while the vessel was actually at sea.

(Dig. 32, tit. 2. *De Nautico Fœnere*; Molloy, *De Jure Maritimo*, lib. ii. c. 11; Arnould, *On Marine Insurance*.)

BOUNTY. 1. A term used in political economy to signify an advantage, chiefly a pecuniary advantage, or premium, allotted and paid by the state, for the export or import of particular articles, or in respect of the production or manufacture of specified commodities, or to persons who employ ships in certain branches of commerce; the object being to encourage and foster the export or import trade of the nation, as embracing those particular articles, to attract industry and capital into the specified branches of production or manufacture, or to engage a larger portion of the shipping interest to turn their attention to the particular lines of commerce designated. In this country the idea of encouraging special modes of enterprise is observable very early in our legislature; but to trace the history of it would, under no circumstances, prove very profitable to the reader, and would be quite impracticable within the limits of this article. Suffice it to say that bounties were held out, by the legislature, in directions so different, and for purposes so various, at different times, that it is most difficult to discover anything in the nature of a governing idea, tending to a defined object, in the vacillating laws that have been passed on this head. Thus in the years 1670 and 1689 respectively, there were enacted bounties on the exportation of corn; in 1795 and 1800 respectively, there was a bounty on the importation of it. The fisheries on various parts of our coasts, especially those of Scotland and Ireland, have perhaps been the fields of industry to which bounties have been most largely and perseveringly applied. The bounty, which had been long continued, under different forms, to the whale fishery, ceased in 1824. The general question of bounties and their impolicy is discussed by Adam Smith in his 'Wealth of Nations,' book iv. chap. 5; and the subject has also been treated in a very complete manner by the late Mr. Ricardo in his 'Principles of Political Economy and Taxation.' When Postlethwaite published his 'Dictionary of Commerce,' in 1774, bounties were "very numerous." After the publication of Adam Smith's work bounties began to be regarded with less favour. They are now no longer relied upon as a means of furthering the true interests of commerce. Adam Smith remarks: "By means of bounties our merchants and manufacturers, it is pretended, will be enabled to sell their goods as cheap or cheaper than their rivals in the foreign markets, . . . We cannot (he adds) force foreigners to buy their goods, as we have done our own countrymen. The next best expedient, it has been thought, therefore, is to pay them for buying." Bounties in truth effect nothing more than this. The propositions maintained by Adam Smith are, that every trade is in a natural state when goods are sold for a price which replaces the whole capital employed in preparing and sending them to the market, with something in addition in the shape of profit. Such a trade needs no bounties. Individual interest is sufficient to prompt men to engage in carrying it on. On the other hand, when goods are sold at a price which does not replace the cost of the raw material, the wages of labour and all the incidental expenses which have been incurred in bringing them into a state fit for the market, together with the manufacturer's profits; that is, when they are sold at a loss, the manufacturer will cease to produce an unprofitable article; and this particular branch of industry will soon become extinct. It perhaps happens that the general interests of the country are thought to be peculiarly connected with the species of industry in question, and that it therefore behoves government to take means for preventing its falling into decay. At this point commences the operation of bounties, which are devised for the purpose of producing an equilibrium between the cost of production, the market-price, and a remunerating price, the last of which alone promotes the constant activity of every species of industry. Smith observes, "The bounty is given in order to make up this loss, and to encourage a man to continue or perhaps to begin a trade of which the expense is supposed to be greater than the returns; of which every operation eats up a part of the capital employed in it; and which is of such a nature that if all other trades resembled it, there would soon be no capital left in the country." And he adds: "The trades, it is to be observed, which are carried on by means of bounties are the only ones which can be carried on between two nations for any considerable time together, in such a manner as that one of them shall always and regularly lose, or sell its goods for less than they really cost. . . . The effect of bounties, therefore, can only be to force the trade of a country into a channel much less advantageous than that in which it would naturally run of its own accord." One of the most striking instances of the failure of the bounty system occurred about the middle of the last century in connexion with the white herring fishery. Tempted by liberal bounties, persons rashly ventured into the business without a

knowledge of the mode of carrying it on in the most economical and judicious manner, and in no very long space of time a joint-stock of 500,000*l.* was nearly all lost.

There is however a distinction on this subject, which some consider important: it is that which subsists between a bounty given to "enable our merchants and manufacturers to sell their goods as cheap or cheaper than their rivals in the foreign market,"—and a bounty which is given in the hope of raising up in time a manufacture or production, so as to naturalise it, as it were, in the soil which has adaptations for its successful prosecution, but where the taste or turn for taking it up has hitherto been found wanting. This is the species of bounty which, in spite of all the arguments of close reasoners, the statesmen of Europe and other parts of the globe, have, in their several spheres, for many generations, shown a strong determination to adhere to, as a line of useful policy. It is held by some that the policy of bounties has not always been followed by the disastrous results which the abstract doctrines of political economy lead us to anticipate, and they take as an instance to the contrary the case of the beet-root cultivation for the purpose of sugar-making in France. The scheme originated with Napoleon I. in 1811, and was of course "bolstered up" by all kinds of bounties, preferences, and advantages which it was in the power of a despotic government to bestow. At first only from 1½ *lb.* to 2 *lb.* of sugar was the produce of 100 *lb.* of beet-root; in 1836, the system being steadily continued, the produce had risen to 7 *lb.* and 8*lb.*, and it is said that this sugar, by means of improved chemical appliances and advanced skill, has taken its place in the French markets and competes with colonial sugar. Here, then, it is alleged, is an instance in which a government, looking more to the future than to the present, have, by a policy of encouragement, and no doubt at an immediate loss, and doing violence to scientific rules, at length secured to the country a valuable internal manufacture which affords a large field for the remunerative employment of capital, and yearly absorbs larger quantities of native labour. On the other hand, it may be alleged, that the same amount of capital and labour might have been employed in the commercial exchange of the natural and established products of France for colonial sugar; and that the industry of the country would have been more properly stimulated, and the wants of the consuming population more advantageously supplied, by this exchange of commodities, than by forcing a manufacture which, however it may be partially successful, can never really produce a cheaper commodity than can be had by buying in the cheapest market. The protective system of French commerce, in general, it may be observed, rests upon the same artificial foundation as that of the beet-root manufacture. It is said, also, in favour of bounties, that no one making himself acquainted with the stores of information that have been collected and laid before parliament by various committees, and otherwise, respecting the possible value of the fisheries on the northern coasts and islands of Scotland, and most of the coast of Ireland, can doubt that if by any means the inherent, and it would seem almost indomitable, repugnance to the sea, which characterises the Celtic races, could be overcome, and a sufficient amount of capital and industry could be determined to the vigorous prosecution of those fisheries, incalculable benefits would be conferred on the habitually poverty-stricken and listless populations of those coasts, and a great, and, in many ways most advantageous, trade might be established.

The system of bounties on the exportation of corn was abandoned in this country in 1815; and those on the exportation of linen, and several other articles ceased in 1830. In the same year also ceased the bounties that had been for a long time granted by the legislature for the encouragement and improvement of the British and Irish fisheries, 7 Geo. IV. c. 34; thus putting an end to the payment of any bounties whatever of the class now treated of, and granted by authority of the legislature.

Analogous to and closely connected with this description of bounties is the system of drawback of duties upon the exportation of articles, a system which is still maintained in certain cases. [DRAWBACK.]

2. Bounty, or the Queen's bounty, is a term used to signify a sum of money given by government to persons enlisting in the army or navy, in order to stimulate the supply of men to those services.

The effect of the latter of these bounties appears to be most prejudicial to the interests of commerce. In the spring of 1859 a Royal Proclamation appeared offering a bounty of 10*l.* to able seamen, 5*l.* to ordinary seamen, and 3*l.* to landsmen, who would enlist or enter themselves in the Royal Navy. Before midsummer of the same year, it was stated in Parliament, that since the proclamation the wages of seamen in the mercantile service had been raised 20*s.* a month; that is, the offer of the Government bounty caused an increase in the pay of the 300,000 men who are calculated to be employed in the mercantile marine, of 12*l.* a year per man.

BOUNTY, QUEEN ANNE'S. [BENEFICE.]

BOW. [ARCHERY.]

BOW, in *Music*, a machine used for drawing out the sounds from—that is, for playing on—stringed instruments of the violin kind. The bow consists of: 1. the stick, which should be of hard elastic wood, Brazil wood being generally used for the purpose; 2. of from eighty to a hundred horsehairs; and 3. of a nut regulated by a screw, by which more or less tension is given to the hairs. The violin bow was very short in Corelli's time, but gradually increased in length, till Viotti,

whose *dictum* in whatever concerned his instrument was received as law, fixed it at twenty-eight inches. The violoncello bow is larger and stronger. That for the double-bass is short and strong, and the stick is bent, forming something like the segment of a circle, of which the hairs when stretched are the chord.

BOYAR or BOYARD, the general name for the fief-holders among the Slavonic races, and who ultimately formed the nobility in Russia, Moldavia, and Wallachia. The original nobility of Russia were composed of persons descended from the leading warriors of the first Russian monarch, Rurik and his successors, who, like the Norman warriors under our own William I., received large fiefs in the country which their valour had enabled their chief to win. The fiefs seem to have been held by the sole tenure of military service; they paid no imposts to the prince, but every boyard had in his own possession the same powers and right of customs and tribute which himself had on his domains. The fierce struggles between kings and nobles which we read of in other countries were not known in Russia. Various causes have been assigned for this; the veneration generally entertained for the blood of Rurik was doubtless one; to which we may add the circumstances which combined to prevent any great power from being concentrated in the hands of individual nobles. In the first place, the scarcity of cities and strongholds prevented any of the military leaders from perpetuating themselves in their commands; and when the empire was divided into a multitude of small principalities, under the general and indefinite superiority of one Grand Duke, secondary fortunes were subject to continual mutation in the struggles which were always taking place among the princes, and which resulted from the singular law of succession, by which the brother of a deceased prince, and not his son, succeeded to the vacant appanage. It was also an unfavourable circumstance resulting from this law, that the prince of the lateral branch was usually a stranger in the appanage to which he succeeded, and that he generally came to it with a train of nobles and followers who engrossed his favour and preference. In fact, the princes themselves had more analogy than the boyards to the turbulent nobles of France and England; and the boyards themselves resembled the knights, who in those countries regarded the barons as their immediate superiors.

The boyards of Russia, then, owed their final elevation to the extinction of the petty principalities, and to the establishment of the hereditary principle in the succession to the grand dukedom. They had preserved to themselves very extensive privileges and immunities, which were felt to be inconvenient to the power of a despotic monarch. Under Ivan many of these privileges were taken from them, such as their hereditary privilege to certain offices, and their right to transfer their allegiance; but he at the same time bestowed offices on many of them, with a prohibition against leaving the court. This system by degrees reduced them into mere dependents on court favour; and, in fact, the defection of the nobles from their immediate superiors, in order to avail themselves of the more certain protection and larger favours which the Grand Dukes were enabled to offer after the alteration of the order of succession, sealed the ruin of the petty princes, whose contentions had before distracted the empire. From this time we find the boyards occupying trusts which only princes had previously been privileged to hold; and no principle, separately from the general usages of the country, remained to distinguish the Russian nobles from those of other European countries, to which Peter the Great elevated them by his regulations. The distinction, while it existed, operated in giving a very peculiar tone to the early history of the Russian monarchy.

Boyars continue to exist in Moldavia and Wallachia, with many of their original privileges, and much of their original power and influence.

BOYEAU is any trench executed by the besiegers of a fortress to serve as a covered communication, or line of approach, during the progress of the siege. It receives the denomination of a parallel, an oblique, or a zig-zag boyeau, according to the line of its direction with respect to the general front of the works attacked. [TRENCH.]

BOYLE'S FUMING LIQUOR. This compound which is identical with hydrated bisulphide of ammonium is obtained by passing sulphur and ammonia through a red hot porcelain tube; or by igniting together 3 parts of slaked lime and 2 of sulphur, and then distilling 3 parts of the product with 2 of chloride of ammonium and 1 of sulphur. It is a yellow foetid oily liquid which often deposits lamellar yellow crystals on cooling. It is decomposed by acids with the evolution of sulphuretted hydrogen and deposition of sulphur.

BRACELET. [ARMILLA.]

BRAHMA, a Sanscrit word, the name of the Supreme Being in the religious system of the Hindoos. The primitive meaning of the word is not quite clear; it is evidently connected with the verbal root *brih*, "to grow, to expand," whence *brihat*, "great;" and has been explained by some as properly implying "the widely expanded Being." The crude form of the word, or the name in its uninflected state, is *Brahman*, and it is of great importance well to distinguish a two-fold use of that term, accordingly as it is declined as a substantive of the neuter or of the masculine gender. When inflected as a substantive of the neuter gender, its termination in the nominative case is a *short a*, *Brahmā* (sometimes written *Brahme* or *Brahm* in English works on Hindoo mythology), and thus declined it designates the essence of the

Supreme Being in the abstract, devoid of personal individuality. When treated as a masculine word, it takes a *long ā* in the nominative case, *Brahmā*, and thus modified, becomes the name of the first of the three gods who constitute the trimurti or triad of principal Hindoo deities.

Brahmā, the impersonal divine substance, is with the Hindoos not an object of worship, but merely of devout contemplation, and he is addressed as Om, or Aum, a reverential word, which no Hindoo pronounces aloud. According to the Védānta system of philosophy, which recognises the ancient sacred writings of the Hindoos as the authority of the doctrines which it advances, *Brahmā* is the great source from which the visible universe and all the individual deities of mythology have sprung, and into which all will ultimately be re-absorbed. "As milk changes to curd, and water to ice, so is *Brahmā* variously transformed and diversified, without aid of tools or exterior means of any sort. In like manner, the spider spins his web out of his own substance; spirits assume various shapes; and the lotos proceeds from pond to pond without organs of motion." "Ether and air are by *Brahmā* created; but he himself has no origin, no procreator nor maker, for he is eternal, without beginning as without end. So fire, and water, and earth, proceed immediately from him, being evolved successively the one from the other, as fire from air, and this from ether." The human soul, according to the same authority, "is a portion of the supreme ruler, as a spark in the fire. The relation is not as that of master and servant, ruler and ruled, but as that of whole and part." It is subject to transmigration, and the route on which, after the death of the human individual, it proceeds to its ultimate re-absorption in the divine essence, is variously described in divers texts of the Vēdas. "But he who has attained the true knowledge of God does not pass through the same stages of retreat, proceeding directly to reunion with the Supreme Being, with which he is identified, as a river, at its confluence with the sea, merges therein altogether. His vital faculties, and the elements of which his body consists, are absorbed absolutely and completely; both name and form cease; and he becomes immortal, without parts or members." (Passages from the 'Brahma-sūtras,' or aphorisms on the Védānta doctrine, by Bādarāyana, translated by Mr. Colebrooke; 'Transact. of the Roy. Asiat. Soc.,' vol. ii. passim.) The Vēdas do not teach hero-worship, and make but slight allusions to the incarnations or avatars, which have so largely increased the number of gods. The Vēda was succeeded by the Védānta, and that by the Purānās, each becoming less monotheistic, until the Purānās have ended in a pantheistic idolatry.

Brahmā, as an individual deity in mythology, though originally represented as the almighty creator, preserver, and destroyer, has subsequently become three distinct beings, as *Brahmā* the creator, with Vishnu the preserver and sustainer, and Siva the destroyer. His epithets are numerous, and the following are some of those given by Mr. H. H. Wilson: *Viśvābhavāna*, the creator of the universe; *Mahā purushā*, great or supreme spirit; *Indriyātmā*, one with (or lord of) the senses. But exclusive worshippers of *Brahmā* and temples dedicated to him do not now seem to occur in any part of India: homage is however paid to him along with other deities. The Brahmans, in their morning and evening worship, repeat a prayer addressed to *Brahmā*; and at noon likewise they go through certain ceremonies in his honour: on the occasion of burnt offerings, an oblation of clarified butter is made to him, but it does not appear that bloody sacrifices are ever offered to *Brahmā*. In the later Purānās, as in that of 'Bhagavat Dasam askand,' translated by Theodore Pavie, Vishnu or Krishnu, and Siva, rise into independent deities; and as they represent the principles of good and evil, a continued contest is the result. The other deities, of whom there are numbers, are now represented as having been either avatars of *Brahmā* in the form of Vishnu, or his descendants either immediately or from Vishnu or Siva. *Brahmā*, in the earlier Vēdas, is stated to have preceded the existence of matter; but Vishnu is at once Purusha (spirit), Prudhāna (crude matter), Vyakta (visible form), and Kāla (time); and the acts of creation, preservation, and destination came to be allegorised into personages. At the full moon of the month Māgha (January-February), an earthen image of *Brahmā*, with that of Siva on his right and that of Vishnu on his left hand, is worshipped; and dances, accompanied with songs and music, are performed as at the other Hindoo festivals. When the festivities are over, the images of the three gods are cast into the Ganges. A particular worship is paid to *Brahmā* at Pushkara or Pokher in Ajmere, and at Bithore in the Doab, where he is said to have performed a great and solemn sacrifice on completing the act of creation; and the pin of his slipper, which he left behind him on the occasion, and which is now fixed in one of the steps of the Brahmaverta Ghat near Bithore, is still an object of adoration there.

(H. H. Wilson, *The Vishnu Purānā, a System of Hindu Mythology and Tradition*, 1840; Pavie, *Krishnu et sa doctrine*, Paris, 1852; Count M. F. F. Björnstjerna, *Die Theogonie, Philosophie und Kosmogonie der Hindus*, Stockholm, 1843.)

BRAHMANS. [HINDOOS, CASTES OF.]

BRAIN, DISEASES OF. The morbid conditions of the brain are of great importance, and will be found treated of in this work under the various heads of the most distinctive forms which these diseases assume. They will be found under the following heads:—APOPLEXY, CONVULSIONS, CHOREA, DELIRIUM-TREMENS, ENCEPHALITIS, EPILEPSY, HYSTERIA, INSANITY, MENINGITIS, PARALYSIS.

BRAKE, or BREAK, in Machinery, a contrivance for retarding or arresting motion, by creating an amount of friction too great to be overcome by the moving power, or the momentum of the machine. Brakes generally consist of blocks of wood so connected with a system of levers or screws that they may be pressed firmly against the periphery of a wheel mounted upon the main axle of the machine; but in some cases, instead of a block of wood, a strap or belt of iron, of sufficient length to embrace one-half of the periphery of the brake-wheel, or a series of small blocks of wood attached to the concave surface of such a strap, is used. [SAW-MILL; ROLLING STOCK; WIND-MILL.]

BRAMAH'S PRESS. [HYDRAULICS.]

BRAMINS. [HINDOOS, CASTES OF.]

BRAND IN CORN. [BURNT-EAR.]

BRANDY. This well-known liquid is the alcoholic or spirituous portion of wine, separated from the aqueous part, the colouring matter, &c., by distillation. The word is of German origin, and in its German form, *brantwein*, signifies burnt wine, or wine that has undergone the action of fire. Brandies however have been made from potatoes, carrots, beet-root, pears, and other vegetable substances; but these varieties are all inferior to true brandy. Brandy is prepared in most wine countries, but that of France is the most esteemed. It is procured not only by distilling the wine itself, but also by fermenting and distilling the *marc* or residue of the pressings of the grape. It is procured indifferently from red or white wine; and different wines yield very different proportions of it, the strongest of course giving the largest quantity. Brandy obtained from *marc* has a more acrid flavour than that from wine; this appears to be occasioned by an oil contained in the skin of the grape, which when separated proves so acrid that a single drop would deteriorate several gallons of good brandy. The celebrated brandy of Cognac, a town in the department of Charente, and that brought from Andraye, seem to owe their excellence to being made from white wine, so fermented as not to be impregnated with this oil. Like other spirit, brandy is colourless when recently distilled. By mere keeping, however, owing probably to some change in the soluble matter contained in it, it acquires a slight colour, which is much increased by keeping in casks, and is made of the required intensity by the addition of burnt sugar, or other colouring matter.

The production of brandy, so far as obtaining the alcoholic principle is concerned, is described under DISTILLATION.

Although brandy drinkers despise patent or British brandy, yet it is a question whether this may not be quite as pure and strong as much that goes by the name of foreign brandy. So enormous is the duty paid on foreign brandy, that the French manufacturers are induced to strengthen their cognac artificially by spirits of wine, and the English dealers to increase its bulk by water and other additions. Foreign brandy ought to be a little 'over proof;' but it is frequently 12 to 15 degrees below proof. Dr. Normandy makes the following remarks on the worst or really fraudulent brandy:—"Brandy, when newly distilled, is white; but that met with in commerce is always of a yellowish, brown, or dark brown colour, due to the presence of some extractive matter, and of tannic acid, which it has dissolved from the oak casks in which it has been kept for a long time. But in order to simulate this colour of genuine brandy, the brandy of commerce is nothing else than new brandy or alcohol, at once converted apparently into old brandy by means of caramel, or burnt sugar."

British brandy, for which patents have been obtained by many English distillers, is the result of numerous attempts to produce, from malt spirit, a liquor that shall bear a close resemblance to foreign brandy. The best malt spirit is the basis of all the British brandies; and the flavour, colour, and degree of strength, are brought about by the addition of some among the following long list of ingredients: water, red tartar, acetic ether, French vinegar, French plums, wine-bottoms, tincture of catechu, oak shavings, bitter almonds, burnt sugar, tincture of vanilla, oil of cassia, rum, &c.—each manufacturer having a favourite recipe of his own. It is said that where black tea is cheap, as in America, it is often employed to give an imitative brandy-roughness to coloured spirits.

Brandy is an ingredient in a large number of cordials and liqueurs, such as cherry brandy, carraway brandy, lemon brandy, orange brandy, peach brandy, raspberry brandy, and the like. They all bear a family resemblance in so far as they consist of brandy, flavoured by the fruits or seeds whose name they bear, sweetened with sugar, and rendered fragrant with spices.

Regarded in its commercial features, brandy is a commodity of considerable importance. In all wine-producing countries, a part of the produce of the vineyards is converted into brandy; and in some of those countries a portion of the spirit is employed to give strength to the remaining portion of the wine. The fiery wines of Spain, Portugal, Madeira, the Cape of Good Hope, and other countries, are thus treated. There are no certain means of knowing what proportion of the produce is distilled in different places. The only country in which, as far as we know, any estimate of this kind has been made, is France; where a commission, appointed to inquire concerning the duties levied upon liquors, has given an estimate of the produce of the vineyards, and the mode of its disposal. From this it appears that about 15 per cent. of the wine is made into brandy; but as the spirit obtained varies in quantity according to the quality of the wine from which it is made, it is not possible to state its amount with precision. It has been estimated

that the quantity of brandy annually made is equal to about 20,000,000 English gallons, of which about one-third is exported, leaving 13,000,000 gallons for consumption in France. The principal exportations are made from the Charente, from Bordeaux, and from the port of Cete in the Mediterranean. From Charente comes the brandy of Cognac, which is principally used in England, to which country three-eighths of all the shipments of French brandy are ordinarily made; about one-fourth is taken by the Americans, chiefly from Bordeaux and Cete; and the remainder is shipped, in comparatively small quantities to the French Antilles, to India, and to various countries in Europe, chiefly to the north. Until the early part of the present century, considerable purchases of Spanish brandy were made by the English government for the use of the navy; but at that time, with the view of encouraging our West India colonies, rum was substituted. The shipments of brandy from Spain are principally made at Barcelona, whence about 11,000 pipes (about 1,200,000 gallons) are annually exported. Of this quantity 3000 pipes are sent to Cuba, 6000 pipes to the former dominions of Spain in America, and 2000 pipes to the north of Europe.

The consumption of brandy in England was greater seventy years ago than it was twenty years ago, owing chiefly to the raising of the duty from 6s. to the enormous amount of 22s. 6d. per gallon. In estimating the import, it is necessary to distinguish between the portion retained for home consumption and the portion re-exported to India and the colonies. The following figures exhibit the total imports in the last three years; but it must be borne in mind, that the quantity entered for home consumption, plus the quantity re-exported, do not necessarily amount together to the quantity imported; seeing that a considerable portion may remain in bond, under the charge of the Customs' department, awaiting the time when the owner may choose to pay the duty for home consumption. The quantity entered for home consumption and the quantity re-exported may, in other instances, exceed the quantity imported in that year; in such case the reserve stock of the previous year must have been drawn upon.

	Quantities Imported. Proof Gallons.	Entered for Home Consumption. Proof Gallons.
1856	2,540,438	1,534,694
1857	2,899,952	1,291,499
1858	1,064,661	1,108,105

The quantities re-exported were as follow:—

	Proof Gallons.
1856	1,539,075
1857	1,047,763
1858	671,474

The brandy trade of these three years exhibited strange fluctuations, as will be evident from an inspection of the above figures.

British or imitative brandy is among the alcoholic liquors which pay excise duty.

BRANK. [BUCK WHEAT.]

BRASS, *Æs* of the Romans, is an alloy of copper and zinc, which has been known and used from the remotest antiquity; it is now extensively employed both for useful and ornamental purposes.

The direct method of forming brass is by melting together its constituent metals; but it was manufactured long before zinc was obtained in its metallic form. Calamine, an ore of zinc, was mixed with copper and charcoal; and the zinc being, by the well-known action of the carbonaceous matter, reduced to the metallic state immediately combined with the copper, without separately exhibiting metallic properties. In Germany brass appears to have been made for centuries before the manufacture was introduced into England: this is stated to have been done by a German, who established works at Esher in Surrey in the year 1649.

When the requisite furnaces have been erected, the next step in the process is that of reducing copper to a convenient form for ensuring its ready combination by extending its surface. This is effected by pouring the melted metal into water; by which process what is called *shot copper* is obtained, in pieces varying in size from that of small shot to that of a bean.

The next process is to prepare the calamine, which is a carbonate of zinc. This is first broken into small pieces, and then heated to redness in a reverberatory furnace. In this way, by the loss of carbonic acid and moisture, one ton of calamine is generally diminished to about twelve cwt., and it is when cold reduced to a fine powder and washed.

The materials being thus prepared, 45 pounds of the shot copper, 60 pounds of the powdered calamine, and a quantity of powdered charcoal equal to it in bulk, are carefully mixed and put into eight earthen crucibles, this being the number placed in each furnace, made of a peculiar form. There is also commonly mixed with these ingredients a quantity of scrap brass. When the fire has been continued for about seven or eight hours, the operation is finished. Supposing 40 pounds of scrap brass to have been added to the above-mentioned quantities of the ingredients, a plate of brass is obtained by pouring the metal into granite moulds, which is generally about 5½ ft. in length and weighs about 108 pounds. This plate is used for rolling into thin sheets called latten. Very frequently the metal is poured into cast-iron moulds, by which bars about eight inches in length are obtained: these bars

are employed by those who cast brass into small goods, or who mix it by melting with additional quantities of copper so as to produce metal having different shades of colour, as tombac, pinchbeck, &c. Sometimes blende, or the sulphuret of zinc, is employed instead of calamine; it is first roasted to dissipate the sulphur, and there remains an oxide.

Such is the process formerly employed, and even still occasionally used for the manufacture of brass, but it is now almost universally made by the direct fusion of its constituent metals, copper and zinc. 51 lbs. of old brass free from solder, 55 lbs. refined and granulated copper, and 24 lbs. of zinc are melted together in four crucibles, the loss being about 2½ to 4 lbs. upon the total quantity.

Brass for various purposes is made of different proportions of the two metals, and consequently possesses different qualities; its general properties are, that it has a well-known fine yellow colour, is susceptible of receiving a high polish, and is only superficially acted upon by the air. It is very malleable and ductile when cold, and consequently may be beaten into thin leaves and drawn into fine wire: at a high temperature it is brittle. The specific gravity of brass is greater than that deducible from the specific gravities of the metals which constitute it, as shown by the following statement.

Brass, containing copper 70 and zinc 30, would give a calculated specific gravity of 8.390; but by experiment it is found to be 8.443: when the proportions are copper 80 and zinc 20, the calculated is to the actual density as 8.490 to 8.560. On comparing the composition and density of different kinds of brass, it appears that the density increases with the proportion of copper, as might indeed be expected, and that it is sometimes even equal to that of the copper itself.

Brass is more fusible, sonorous, a worse conductor of heat, and harder, than copper. It is readily turned in a lathe, and is consequently well adapted not only for philosophical instruments, but those used in manufacturing processes and for domestic purposes. In the state of wire it is most extensively employed in pin-making, and for various other purposes; the thin leaves into which brass is made by hammering are called Dutch metal or Dutch gold.

Authors differ widely as to the best proportions of copper and zinc for making brass. It is stated, in the supplement to the 'Encyclopædia Britannica,' that one part of copper and two parts of zinc are the best proportions for common brass; and that one part of each forms prince's metal of a fine yellow colour. Mr. Parkes, 'Essays,' p. 210, states (and we believe he obtained his information from an accurate source) that the most useful proportions are two parts of copper to one part of zinc, which are not far from one equivalent of each metal. Berthier's analysis of the brass wire of Jemappes confirms the probability of this statement, for he found it to consist of—

Copper	64.2
Zinc	33.1
Lead	.8
	98.1

The small quantity of lead is, of course, to be regarded as an accidental admixture. Bristol brass consists of—

Copper	65.15
Zinc	34.85
	100.00

Some old Dutch brass, much approved of by watchmakers, contained

Copper	69.55
Zinc	30.45
	100.00

Mr. D. Forbes has observed that a silver-white brass may be formed by alloying seven equivalents of copper with eight equivalents of zinc; but if the quantity of zinc be either increased or diminished, the alloy has the usual colour of brass.

The following table exhibits the composition of several other varieties of brass:—

	I.	II.	III.	IV.	V.	VI.	VII.	VIII.	IX.
Copper	65.8	64.6	63.7	82	70.1	80	90.5	91.2	60
Zinc	31.7	33.7	33.5	18	29.9	17	7.9	5.6	40
Lead	2.2	1.5	.3	—	—	—	1.6	1.4	—
Tin	.2	.2	2.5	—	—	3	—	1.8	—
	99.9	100.0	100.0	100	100.0	100	100.0	100.0	100

No. 1. is brass from Stolberg in Germany, and No. 2. from Jemappes in France; both are well adapted for the lathe, and are highly esteemed. Nos. 3. and 4. are recommended by D'Arcet for gilding; they fuse easily, can be chased or turned with facility, and take up little gold in the gilding operation. No. 5. is perfectly free from lead and tin, and consequently works well under the hammer; it is made at Romilly, and is much esteemed. No. 6. is employed in France for ornamenting fire-arms; its colour is good, and it is very permanent in the air. No. 7. Chrysocolla. No. 8. Statuary brass. A statue by the brothers Keller in the palace of Versailles is cast from this brass. No. 9. Muntz metal, used for sheathing ships, admits of being rolled while hot.

In concluding this article, we shall give the method of analysing brass proposed by Mr. Keates, in the 'Annals of Philosophy,' vol. iii. N. S., p. 326.

Dissolve the brass in dilute nitric acid, add a little sulphuric acid, and evaporate to dryness; redissolve in excess of dilute sulphuric acid, dilute the solution, and boil pieces of polished iron in it, until the solution becomes nearly colourless; filter it while hot, wash the precipitated copper with dilute sulphuric acid, and afterwards with boiling water: this, when dried, is to be put into a crucible, covered with charcoal powder and melted; the copper being cleansed from any adhering charcoal, is then to be weighed.

The filtered solution, from which the copper has been separated, is to be boiled with nitric acid to peroxidise the iron; neutralise the acid with carbonate of soda, and precipitate the iron by ammonia, using an excess of the latter so as to redissolve the oxide of zinc at first precipitated; filter the solution, and add to it hydrochloric acid, evaporate to dryness, and heat the dry mass in a platinum crucible to drive off the chloride of ammonium; dissolve the residuum in dilute hydrochloric acid, and precipitate by carbonate of soda; the precipitate, after being washed and dried, is heated to redness; every 40.5 parts of this precipitate is equal to 32.5 parts of metallic zinc.

Another and more simple method is the following: Dissolve the brass in a considerable excess of nitric acid; pass sulphuretted hydrogen gas, also in excess, through the solution; the copper only is precipitated, which is to be treated with nitric acid, the sulphur separated by filtering, and the oxide of copper precipitated by boiling with soda: 39.7 grains of this precipitate indicate 31.7 grains of copper.

The solution remaining after the separation of the sulphuret of copper is to be boiled to expel the excess of sulphuretted hydrogen, and then precipitated by carbonate of soda: the precipitate, when ignited, is oxide of zinc, 40.5 grains of which indicate 32.5 grains of metallic zinc. (Smith in 'Lond. and Edin. Phil. Mag.' vol. viii.)

The general properties of brass are, a fine yellow colour, a susceptibility of a high polish, and a power of being only superficially acted upon by the air. It is brittle at a high temperature, but very malleable and ductile when cold. Its specific gravity is greater than that deducible from the specific gravities of its constituent metals. It is more fusible than copper, a worse conductor of heat, and harder. The facility with which it may be cast, and turned in a lathe, or otherwise worked, renders it peculiarly useful in the construction of mathematical instruments, and the smaller parts of machinery. Brass wire is extensively used in pin-making, and for various other purposes. *Latten* is a name sometimes given to thin sheets of rolled brass; and *Dutch metal*, or *Dutch gold*, is brass beaten out into very thin leaves.

A mode of using sheet brass or other metal for ornamental purposes was introduced a few years ago, in which the appearance of solid metal might be obtained without the weight, by using a wooden core to place the sheet metal upon. The method is useful for making cornice-poles, mouldings, or other articles of continuous form and pattern. The wood is first shaped, by planes and other tools, to the required pattern; the sheet metal is placed upon it; and the two together are drawn through a suitable die, which unites them by driving the edges of the metal into the substance of the wood. If the pattern be a plain one, it is struck down upon the wood by the die through which it passes; but if the pattern be full and complicated, it is imparted to the sheet metal by swaging tools and dies, previous to the application of the metal to the surface of the wood.

The ordinary mode of making brass tubes is as follows: A tube is first cast much shorter and thicker than will ultimately be required; this is drawn through dies differing in diameter by degrees, until it is reduced to the required size of bore. The brass is annealed from time to time, to enable it to bear the successive drawings; and it is lastly "pickled" in dilute acid, to remove the scales and discoloration. In 1851, Mr. Green patented a method by which the annealing and cleansing might be more carefully attended to in making the brass tubes for the boilers of locomotives.

Not only are the filings and turnings of brass sold for re-melting, but the very ashes of the furnaces in which the brass has been melted find a market—there being in them a sufficient per-centage of metal to pay the expense of smelting.

The brass manufacture is one of the most important of the branches of industry at Birmingham. Lamps, chandeliers, tubes, pipes, gas-fittings, bedsteads, cornices, frames, and numberless other articles, are now made largely in this metal. One of the brass factories, the Cambridge Works, presents a fine example of organisation applied to a special department of industry. Some of the stamping works, also, are noteworthy for the extraordinary number of dies or moulds kept in store for stamping articles in sheet brass.

After supplying home demand, there is a surplus of brass and brass goods for exportation: in the last three years the quantities and values exported were as follow:—

1856	.	.	19,198 cwts.	£121,206 value
1857	.	.	26,960 "	143,953 "
1858	.	.	26,554 "	155,293 "

BRASSES, MONUMENTAL. By "a brass," as the term is commonly used, is meant a plate of brass, which has been imbedded in a stone slab, and fastened down by being laid in melted pitch and riveted

through the stone. The effigy of a person deceased is usually engraved on the brass plate; but brasses are not uncommon in which a foliated or ornamented cross or symbolical device occurs instead of a human figure. In the brasses with figures there is frequently a canopy over the head, and there are often armorial bearings, angels, saints, and other ornaments, together with inscriptions, sometimes on labels, sometimes round the border of the slab, but mostly below the feet of the effigy. These separate parts have been, in almost all cases, engraved on detached plates, each of which is inlaid in its own cavity of the stone. The engraved plates were not originally in the plain state in which they now appear, but were generally burnished and sometimes gilt, and the incised parts were filled with black or coloured resinous substances, and for the heraldic *argent* metal resembling pewter: very rarely enamel was used, as in the celebrated brass of Sir John d'Abernoun, in Stoke d'Abernoun church, Surrey. The plates were sunk level with the surface of the stone, which was generally of a dark colour, and thus became an appropriate background, giving distinctness and relief to the engraved brasses, and adding to the beauty of the figures and ornaments. Slabs with brasses are commonly laid in the pavement of churches or cloisters, but are sometimes on table tombs.

The art of engraving the plates was probably brought to England from Flanders and France, as well as in the earlier periods the plates themselves: the brasses of Cologne appear to have been held in most repute. Early brasses still exist in this country which are known to have been engraved by Flemish artists, and there are many fine brasses still remaining in the churches of Flanders; those of France were for the most part destroyed during the Revolution, when they were converted into coin or cannon; a very few remain in Germany; a few also of foreign manufacture are found in Denmark and Sweden; one in Spain (at Seville); in Italy there is not we believe a single example.

It is impossible to determine when monumental brasses were first introduced into England, most of the oldest specimens having doubtless been destroyed. Brasses with dates as early as about 1208 (as that of Simon de Beauchamp, at St. Paul's, Bedford), are known to have existed. The earliest now remaining in England are those of Sir John d'Abernoun, at Stoke d'Abernoun, 1277, and Sir Roger de Trumpington, at Trumpington, Cambridge, who died in 1289. During the 14th century monumental brasses became more and more numerous; in the 15th century they were in still greater abundance; but towards the close of the 16th the number began to diminish, and they were of a very inferior quality. In the reign of James I. the use of them had become infrequent; and by the close of the 17th century they had almost passed out of date, though two still exist at St. Mary Cray, Kent, of much later dates, namely, to Philadelphia Greenwood, 1747, and to Benjamin Greenwood, 1773. Instances occur of engravings on the backs of brasses; in some cases apparently being unused brasses, but more frequently palimpsests. The number of brasses now remaining in England, though still considerable, is small compared with what it has been. Many were destroyed when the monasteries were suppressed in the reign of Henry VIII.; many have been torn up, and sold as old metal; but the greatest destruction of them took place during the predominance of the Puritans, who regarded them as superstitious, and the neglect, or worse, of subsequent times: the extent to which their destruction has been carried, is but too plainly shown in such a statement as that quoted by the Rev. C. R. Manning, in his chapter on brasses, in Mr. Paley's 'Manual of Gothic Architecture,' that "the pavement of York minster alone contained in the year 1612 one hundred and twenty brasses, of which one hundred and nineteen have disappeared." Probably in few other churches has the destruction been carried quite so far, but everywhere it has been very great. There still remain, however, upwards of two thousand brasses in this country. (Manning's 'List of the Monumental Brasses remaining in England,' and the works referred to below.)

The effigy on a monumental brass is generally represented recumbent on the back, with the hands on the breast placed palm to palm, in the attitude of prayer; and this form applies equally to men and women; but occasionally the figure is represented standing or kneeling. The head usually rests on a cushion, which is sometimes supported by an angel on each side. Military noblemen are generally in full armour; ecclesiastics in the vestments peculiar to their order; ladies have frequently a small dog lying at the feet, probably to typify their affection and fidelity, as the lion at the feet of the knights is typical of courage and nobility. The canopies and other engraved architectural embellishments are often extremely elegant. The canopy is sometimes a pediment with pinnacles and finial; sometimes a foliated arch; and sometimes a foliated arch below a pediment; the canopy is sometimes isolated, and sometimes rests on slender pillars. Occasionally armorial bearings are placed on the pillars and spandrils, of which a specimen is shown in the beautiful brass in Westminster Abbey, of Eleanor de Bohun, wife of Thomas of Woodstock, duke of Gloucester, son of Edward III. The shields of arms, devices, and peculiarities of costume, appropriate each brass to its period in a remarkable manner; and brasses in their turn are found of almost inestimable value in ascertaining the peculiarities of costume, arms, &c., of the several periods of English history. Each period has also a form of alphabetic character almost peculiar to itself, which, in the early brasses, is adhered

to with singular uniformity. Some inscriptions in the Gothic letters are very handsome. Roman letters are rarely used before the reign of Henry VIII., and are generally inelegant enough. The Gothic forms continued to be used occasionally till a late period. Most of the early

inscriptions are in Latin. French inscriptions occur generally from 1350 to 1400. English inscriptions afterwards became more common, but Latin still continued to be frequently used, and there are a few examples of inscriptions in Greek.

Monumental brasses in England have been most abundant in the eastern counties and Kent, partly perhaps in consequence of the contiguity of these counties to the Continent, whence the use of brasses seems to have been introduced, and partly of the want of stone suitable for the effigy in relief, for which the brasses appear to have been substituted. In Wales and the north of England brasses are comparatively rare; only one has been found in Scotland, namely, in Glasgow cathedral; and only two in Ireland (dated 1527 and 1528), in Dublin cathedral. Within the last few years, as a part of the revival of mediæval forms, monumental brasses have again come into use, and many very beautiful brasses have been laid down.

Specimens of monumental brasses are easily obtained by the process called *rubbing*. Paper of moderate thickness, tenacity, and softness, is laid upon the brass, and rubbed with a black or coloured material, which adheres to the paper where the brass is solid, leaving it in its original state where there are incisions, which of course offer no resistance to the rubber. With a little care a perfect fac-simile may be obtained. Shoemakers' heel-ball, or pouch-ball, which is a composition of tallow, wax, and lamp-black, is a very convenient rubber; the operation is clean and easy. Paper of suitable quality and of the full size of a whole slab is manufactured on purpose, as well as suitable heel-balls: but the whitest kind of lining paper used by paper-hangers answers very well.

Another material for making rubbings has been invented by Mr. H. S. Richardson, which is composed of a yellow metallic powder mixed with the adhesive substance of which the rubber is composed, as the lamp-black is mixed with the tallow and wax. When the rubbing is made on a dark-coloured paper, a fac-simile is obtained not easily distinguishable from the original; the figure appears to be the brass itself, and the paper which remains unacted on by the rubber seems to be the stone slab in which the brass is imbedded. Where great sharpness is required, a mixture of black-lead and linseed-oil applied with a rubber of wash-leather on thick tissue paper is found serviceable.

The first collection of copies of brasses was made by Sir John Cullum, Craven Ord, and the Rev. Thomas Cole, not by rubbing in the manner just described, but by a rude process resembling copper-plate printing, which was afterwards worked over by the pen, and cost much time and labour. The collection was sold for 43*l.* to the late Francis Douce, and was bequeathed by him to the British Museum, where it is now in the print-room. A few examples of brasses are preserved in the museums of the Department of Science and Art, at Jermyn Street and South Kensington.

'A Series of Monumental Brasses, extending from the reign of Edward I. to that of Elizabeth, by J. G. and L. A. B. Waller,' is the standard work on monumental brasses; the selection of specimens is very judicious, the plates are exceedingly accurate, and the work is accompanied by explanatory letter-press. See also the Rev. C. Boutell's 'Monumental Brasses and Slabs,' and 'Monumental Brasses of England;' and the 'Oxford Manual of Brasses.'

BRASSIC ACID. [COLZA, OIL OF.]

BRAVURA, in Music (Ital., *courage, intrepidity*), an air consisting chiefly of difficult passages,—of divisions, in which many notes are given to one syllable, therefore requiring great spirit, much *bravery*, in the performer. (See, under the word AIR, *Aria di Bravura*.)

Compositions of this sort have generally no object but the display of the singer's force, volubility, and distinctness of articulation; though some few fine airs of the kind, by Handel, Hasse, Piccini, Guglielmi, Cimarosa, Mozart, &c., still keep alive a taste for this species of vocal music, and thus inferior works in the same style continue to be tolerated.

BRAZIL WOOD, *Colouring matter of*. Commercial Brazil-wood (*Pernambuco-wood*, *Sappan-wood*, *Bukkumwood*, *Saint Martha-wood*, *Wukkum-wood*), the product of several species of *Cæsalpinia*, nat. ord. Leguminosæ, yields its colouring matter [*Brezilin*] to water. The decoction, fine dark red, deepens in colour and improves by age and fermentation. It is used in dyeing and calico-printing as a spirit colour. It furnishes a crimson almost equal to cochineal, but much less permanent. The colouring matter readily combines with alumina or oxide of tin. It is changed to a permanent yellow by the action of dilute acids. Alkalies give it a beautiful purple hue that unfortunately is very transient. Brazil dye may be obtained in a fit state for printing by concentrating the decoction to a quantity about equal in weight to the wood used, precipitating the dun colouring matter with skim milk, and thickening the liquor, cleared by standing, with British gum. Sulphuretted hydrogen and sulphurous acid decolorise decoction of Brazil-wood—strong acids restore the red tint.

According to Chevreul, brezin crystallises in small orange needles. It is partly volatilised, partly decomposed by heat. Nitric acid partially converts it into picric acid. It is soluble in water, alcohol, and ether. Salts of lead and tin give with it a coloured precipitate; solution of alum precipitates a red lake. It is possible that brezin is identical with hematin.

BREACH, the opening formed either by breaching batteries or mines in the rampart of a fortress, to enable the assaulting column to enter. When formed by artillery, the breaching batteries are placed as nearly opposite the place of the desired breach as practicable, in order that the fire of the guns may be nearly perpendicular to the face of the masonry; it is then directed on the escarp revetment, so as to cut a horizontal groove in the masonry of the length of the desired breach, about 80 to 100 feet, at about half or one-third of the height of the revetment from the bottom, if there is no chance of the defenders being able to clear away the *débris*, or about three or four feet above the bottom of the ditch if this be feared. From each extremity of this horizontal groove, two vertical grooves are then made to detach this portion of the masonry wholly from the rest. The fire of the artillery is then directed generally over the detached portion, or what is still better, so as to make a series of vertical grooves parallel to the extreme ones, thereby isolating the counterforts. [REKETMENT.] The masonry then falling into the ditch, a few shells are fired into the rampart to bring portions of the earth down also, which, forming a species of ramp at an inclination of about 45°, the assaulting column is enabled to rush up into the works. In order to form a breach, guns of the heaviest calibre procurable are employed, and they should fire short ranges, to obtain the greatest destructive effect from the fire and accuracy in cutting the grooves. When time and matériel permit of it, the approaches are pushed close up to the works, and the breaching batteries established on the counterscarp. While the breaching batteries are being established and the breach made, a great gallery [MINES] is driven from the besiegers' approaches to the bottom of the counterscarp to give access to the ditch. When, however, from want of matériel the approaches cannot be pushed far enough forward, or from want of time it is not considered expedient to defer the formation of the breaching batteries till the covered-way is crowned, as occurred in most of the sieges in the Peninsula, the breaching batteries are established at some distance from the place, and their fire is consequently not nearly so effective; for not only is the possibility of striking accurately rendered much less, but if the escarp wall should be well covered by the glacis, the shot, in order to strike the wall low down, will have to be fired with small charges, which giving smaller velocities, and therefore a more curved trajectory, pass over the crest of the glacis. At the same time, being

much less certain and effective, a great expenditure of ammunition is entailed, and in fact it is very doubtful, judging by experience, whether anything is gained by thus pressing on sieges. At the same time it must be remarked, that in many old fortresses, the escarp is very much exposed, that is, not well covered by the glacis, especially from some commanding height in the neighbourhood, and in this case there will of course be little necessity for establishing breaching batteries close, and they have occasionally been effective as far as 1000 or 1200 yards.

No precise rule can be given, either as to the length of time or amount of ammunition required to make a breach, as both will vary much under different circumstances. The French, in their siege of Antwerp in 1832, made a breach 80 feet in width with six 24-pounders, from a distance of 55 yards in 34 hours, with an expenditure of 1288 rounds. The English, at the siege of St. Sebastian, to form the main breach, 100 feet in width, used ten guns at a distance of 620 yards, and took 95½ hours, with an expenditure of 13,000 rounds. In the former case we have 16 shots per running foot of breach, and in the latter 130. At Metz, in forming an experimental breach, only 4 shots were required per running foot. In this case, however, the disturbing circumstances of being under fire were wanting to make it a good guide. To form a breach in a revetment, such as that proposed by Carnot (a detached wall covered by an earthen rampart in front), is still more difficult, and was at one time considered impracticable. It was, however, demonstrated by experiments at Woolwich, that it could be effected by heavy guns (68-pounder carronades, and 8-inch and 10-inch howitzers), firing, from a distance of 400 or 500 yards, shot and shell with small charges, at an elevation of about 10° or 15°. These passing over the earthen embankment, struck near the foot of the wall and made a breach 14 feet in width in six hours, with an expenditure of 1400 rounds. The limits of this article will not permit of any further details of this important subject. It is probable, however, that the increased range and penetration of the rifled cannon, at present being experimented on, will render the formation of breaches an easier and more certain operation.

Breaches are occasionally, when the flanking fire is bad, or thoroughly subdued, formed by mining. In this case, a small party of miners is pushed across the ditch, and protecting themselves by blindages [BLINDAGE] from the effect of missiles thrown down upon them from above, proceed to push a gallery into the revetment, which, when it has gone far enough in, bifurcates to the right and left, where chambers are formed for the charges of powder, which are placed immediately behind counterforts, and require some nicety of adjustment as, if they are too large or too small a practicable breach is not made; and indeed at any time it is not a very certain method of forming a breach, as the *débris* of the masonry is usually in such large masses as to present a great obstacle to men attempting to mount.

Lodgments are formed on the breaches, either by open assault, or by the simple and bloodless method recommended by Marshal Vauban in his 'Traité des Sièges' [SIEGE], in which a few sappers, gradually working up under protection of the fire from the trenches, which are armed and kept ready to bring an overwhelming fire on the breach the instant the enemy makes an attempt to disturb them, form a lodgement at the top which, when ready, is occupied by parties in force.

The attack and defence of breaches has always been one of the most sanguinary and frightful of the operations of war. Every means that the ingenuity of man could devise has been at various times resorted to, to make the assault impracticable. The great breach at St. Sebastian was defended by deep pits dug in the ditch in front of the curtain; chevaux-de-frise made of well-tempered sword blades, were fixed in strong wooden beams planted on the top of the breach, while rows of 14-inch shells and powder barrels were laid on the ground at the foot of the breach, and fired by a powder-hose; and during the interval between the cessation of the fire and the assault, the defenders had thickly strewn the ascent with harrows, and planks with nails in them. At the same time cuts were made in the neighbouring parapets, from which a continuous fire of musquetry was directed on the ditch and foot of the breach. The following curious method of defending a breach is mentioned in Vauban's 'Traité de la Défense des Places': At the siege of Châté, a small town in Lorraine, on the Moselle, by Marshal de la Ferté, a tolerable breach having been made, and the garrison when summoned refusing to surrender, the assault was given. During the very height of the combat, the besieged took it into their heads to throw on to the breach five or six hives of bees which happened to be at hand, these, enraged at being so treated, attacked the besiegers and stung them so violently that they were forced to give up and retire into their trenches, where they followed them with such invincible obstinacy, that the trenches were deserted for several days, during which time the defenders repaired the breaches. This was one of the principal reasons for the siege being raised.

BREAD may be divided into two kinds: first, common biscuit bread, made merely from flour and water, without undergoing any fermentation, and which is consequently compact, heavy, and hard; secondly, loaf bread, formed of flour which has been fermented, and which is therefore porous, light, and soft. The seeds of wheat, barley, oats, and rye are principally employed, and in the state of flour, for the making of bread. These grains resemble each other sufficiently in their nature and properties to render it needless to treat particularly of the bread

made from more than one of them; and as wheaten bread is most extensively used, and the properties indicating perfect bread most distinctly exhibited therein, our remarks will apply chiefly to it.

Common or unfermented biscuit bread, which was undoubtedly that first used in the early ages of the world, is made as described under BISCUIT; in this operation no chemical change takes place, but only the mechanical one of moistening the particles of the flour, so as to cause them to adhere in the first instance, and to remain in one mass by the subsequent process of baking.

In bread, properly speaking, the process of manufacture is one of much longer duration, and the chemical action of fermentation is produced in the mixture of flour and water. Wheat flour is composed chiefly of *starch* and *gluten*, with a small quantity of gummy sugar, and of vegetable albumen. Sir Humphrey Davy found, by certain investigations made by him, that wheat sown in autumn contained 77 per cent. of starch, and 19 of gluten; while that sown in spring yielded 70 of starch, and 24 of gluten. The wheat of the south of Europe contains a larger proportion of gluten than that of the north, and hence its peculiar fitness for making vermicelli. According to the distinguished chemist just quoted, oats yielded 59 of starch, 6 of gluten, and 2 of saccharine matter; while the same quantity of rye gave only 6.1 parts of starch, and half a part of gluten. Referring to other pages of the Cyclopædia for descriptions of these two substances, we will simply state here that both take part in the fermenting of dough into bread, and that each renders its own peculiar useful service to the human system when taken as food.

When flour, made into a paste or dough with water, is suffered to remain in a moderately warm place, it undergoes that partial and spontaneous decomposition which is called fermentation, and which, in order to distinguish it from other kinds, has been called, but without sufficient reason for the distinction, the *panary* fermentation. During this fermentation, a portion of the carbon and oxygen of the partially-decomposed flour recombine to form carbonic acid gas; this, during its natural tendency to escape into the air, is arrested in its progress through the dough by the adhesiveness of the gluten, and forms, owing to its retention, numerous cavities in it. It is thus that wheat-flour makes lighter bread than that of oats or rye, owing to the larger quantity of gluten which it contains, by which the bread is rendered more porous and lighter, and consequently more digestible.

This plan of fermentation would, however, require much time. Moreover, the dough thus spontaneously fermented is never quite free from putrescence and acidity, both of which are injurious to the flavour of the bread. To remedy these inconveniences, the process was formerly accelerated by adding to a mass of recent dough a small quantity of old dough in a state of strong fermentation; this was called *leaven*, and the mass to which it was added was said to be leavened. Although the use of leaven was an unquestionable improvement, a still further one was made by the employment of *yeast*, or *yeast*-instead of it; by this the fermentation is much more rapidly and perfectly effected. The exact nature of this ferment has not been ascertained. It is the frothy scum which rises on the surface of beer during its fermentation; it is a very complex substance, and appears to contain gluten; but that alone is not sufficient to account for the effects produced, as gluten is incapable of fermentation *per se*.

Many diversities exist in the art of bread-making; but the following will sufficiently exhibit the main features of the process, as generally conducted. In the water employed to make the dough, which varies in temperature from 90° to 100° Fahr., there is dissolved a certain portion of salt, the quantity of which, however, is always less than that which will finally be required; yeast is now mixed with the water, and then a portion of flour is added. The mixture is next covered up, and set apart in a warm situation; within an hour after which, signs of commencing decomposition make their appearance. The substance thus placed apart is termed, in the language of the bakehouse, the *sponge*; its formation and abandonment to spontaneous decomposition is termed *setting* the sponge; and according to the relation which the amount of water in the sponge bears to the whole quantity to be used in the dough, it is called *quarter*, *half*, or *whole* sponge. The sponge begins to swell out and heave up, in consequence of the generation of carbonic acid gas. If the sponge be of a semi-liquid consistence, large air-bubbles soon force their way to its surface, where they break and dissipate in rapid succession. But when the sponge possesses the consistence of thin *dough*, it confines the gas until expanded equably and progressively to nearly double its original volume: when, no longer capable of containing the pent-up air, it bursts and subsides. This process of rising and falling alternately might be actively carried on, and frequently repeated, during twenty-four hours; but the baker checks it at a particular point, to prevent the bread from becoming sour. He adds to the sponge the remaining proportions of flour and water and salt, which may be necessary to form the dough of the required consistence and size, and next incorporates all these materials with the sponge by a long and laborious course of kneading. When this process has been continued until the fermenting and the newly-added flour have been intimately blended together, and until the glutinous particles of the flour are wrought to such a union and consistence that the dough, now tough and elastic, will receive the smart pressure of the hand without adhering to it when withdrawn, the kneading is for awhile suspended. The dough is abandoned to itself for a few hours, during which time

it continues in a state of active fermentation, now diffused through its whole extent. After the lapse of this time, it is subjected to a second, but much less laborious kneading; the object of which is to distribute the gas engendered within it as equably as possible throughout its entire constitution, so that no part of the dough may form a soddened or ill-raised bread, from the deficiency of this carbonic acid gas on the one hand; or a too vesicular or spongy bread, from its excess on the other.

After the second kneading the dough is weighed out into the portions requisite to form the kinds of bread desired: these portions of dough are shaped into loaves, and once more set aside for an hour or two in a warm situation. The continuance of fermentation soon generates a sufficient quantity of fresh carbonic acid gas within them to expand each mass to about double its former volume. The masses are now considered fit for the fire, and are finally baked into loaves, which, when they quit the oven, have attained a size nearly twice as bulky as that at which they entered it. From the nature of the processes to which it has been exposed, a well-baked loaf is composed of an infinite number of cellules, each of which is filled with carbonic acid gas, and seems lined with or composed of a glutinous membrane; it is this which communicates the light elastic porous texture to the bread.

It has been already observed, that what is sometimes called the *panary fermentation* is not of a peculiar kind: it is the mere vinous fermentation; and Dr. Colquhoun has shown that it depends upon the saccharine ingredient of the flour, though its quantity compared with the others is so small. The fermentation is also probably aided by the conversion of a portion of starch into sugar, as happens in the well-known process of malting.

The nature of the yeast employed in bread-making is a subject of considerable importance: porter yeast is too bitter, but ale and table-beer yeast answer perfectly well. When these are deficient in quantity, yeast is manufactured by a process similar to that of brewing; a wort is made of malt, to which hops and brewers' yeast are added; by this yeast is obtained free from the bitterness which accompanies porter yeast. Carbonate of ammonia is advantageously and extensively used as a substitute for yeast in making the finer kinds of bread: it is a substance which is totally volatilised at a moderate temperature, and though extremely pungent to the smell, and possessed of a strong taste, it imparts neither taste nor smell to the bread, on account of its great volatility.

Salt is used in bread-making, not only for the sake of flavour and colour, but also to stiffen the clammy dough made from new flour. Good flour will bear a greater quantity of salt than bad, and new flour requires more than old, for the reason already stated.

When flour is converted into bread, it is found on weighing it when taken from the oven that it has increased from 28 to 34 per cent. in weight; but when it has been kept thirty-six hours, that which had gained twenty-eight will lose about four pounds. There are, however, several circumstances which influence the quantity of bread obtained from a given weight of flour, such as the season in which the wheat was grown and the age of the flour: the better the flour is, and the older, within certain limits, the larger is the quantity of the bread produced.

When it was found that the panary fermentation is identical in principle with the vinous, and that a little alcohol is produced by it, there arose a notable project, a few years ago, for saving the spirit produced in bread-making. A sum of 20,000*l.* was spent in establishing a bakery at Chelsea, but it was soon found that the projectors had very much misconceived the chemistry of their subject; while neighbouring bakers, by advertising "*bread with the gin in it*," contrived to throw the gin-less bread quite out of popular favour.

Under ordinary circumstances, no machinery is employed in bread-making in England; but patented contrivances do occasionally come into notice. Some years ago Mr. Clayton obtained a patent for a rotatory kneading-machine, in the interior of which knives were placed diagonally; and other mixing and kneading machines have since been invented; but the hand method remains still almost exclusively in force in this country. Our French neighbours understand these things better: they apply more science to the chemistry of eating and drinking. The mixing and kneading are generally effected by hand, but they are more carefully attended to than in England. There is, however, a machine bakery patented at Paris by M. Mouchot, of which Dumas gives a description: the lifting of the flour into the troughs, the admission of water, the mixing, the kneading, the baking, all are effected by the aid of efficient machinery.

A machine for baking bread by steam was introduced into France a few years ago. It consists principally of two concentric cylinders, the inner one of which has numerous perforations. The dough is placed in the inner cylinder, and the steam is admitted to the space between the two cylinders. Half an hour is said to be sufficient for the heat of the steam to bake the bread; but it would appear that there ought to be some mode of drying the bread after this process.

In respect to *ovens*, considerable improvements have been introduced within the last few years; instead of placing fuel in the oven, it is placed on one side, and flues are so arranged as to heat the oven with less waste, more quickly, and with more cleanliness than on the old method.

The public has been rendered justly indignant at the long list of objectionable substances used to adulterate bread;—damaged wheat, beans, peas, potatoes, plaster of Paris, chalk, pipeclay, burnt bones, are all said occasionally to take part in the manufacture of what ought to be wheaten bread. There is a double mischief in all this: it is a robbery in itself; and it leads to the honest as well as the dishonest being suspected by those whose suspicions are aroused, but who have neither inclination nor skill to analyse their bread. Salt, as was before observed, is really a necessity in bread-making.

The varieties of bread used only in a small degree are numerous. There are bran bread, French soup bread, grain bread, household bread, Iceland moss bread, leavened bread, potato bread, &c.—all of which have peculiarities either in the ingredients or in the mode of making.

The most recent and important novelty in bread-making is probably that of Dr. Daughlish, resulting from three patents taken out in 1856, 1857, and 1858, and put in operation at the machine bakery of Messrs. Peek and Frean. The "raising" of bread into a *sponge* is effected, not by fermentation, but by adding carbonic acid gas to the flour under great pressure. The flour is put into a strong thick iron globe; water saturated with carbonic acid gas is forced into it; kneading-knives rotate among the ingredients for a few minutes; the mixing, aerating, and kneading go on all at once; a trap at the lower part of the globe opens, the well-kneaded dough falls out in a thick, solid cylinder, or in a flat ribbon, according to the shape of the orifice; and this cylinder or ribbon of dough fashions itself into loaves of varied shape, according to the arrangement of simple apparatus beneath. The loaves are placed on trays, the trays are ranged on a travelling railway, and the railway conveys them swiftly and systematically into the oven, which is constructed and heated in a peculiar manner. Arrangements are made for the production of bread on a large scale at this establishment, and for selling it to retailers.

Birmingham and one or two other towns have preceded the metropolis in the system of making bread on a large scale, in a few bread-factories, and supplying retail shopkeepers. There are two joint-stock companies in Birmingham for this purpose, both of which realise fair dividends for the capital invested.

In Carlisle, besides the manufacture of bread and biscuits in certain large and well-organised establishments, there is a custom of making wholesome second-class bread by an admixture of maize or Indian corn with wheat in some households. The following instructions for this purpose have been given: Take seven pounds of Indian corn flour, and pour upon it four quarts of boiling water, stirring all the time. Let it stand till the temperature becomes lukewarm, and then mix it with seven pounds of fine wheaten flour, to which a quarter of a pound of salt has been previously added. Make a depression on the surface of this mixture, and pour into it two quarts of yeast, which should be thickened to the consistence of cream with some of the flour. Let all remain quiet during the night, and on the following morning knead the mass, and allow it to stand for three hours. Then divide the dough into loaves, and bake them in tins, in which they should be allowed to stand for half an hour before baking. From these materials about thirty-two pounds of nutritive bread can be obtained.

Referring to the article YEAST, for an account of the chief modes of obtaining or producing that (hitherto considered) indispensable ingredient in bread, we may here mention an item of statistics which shows how large must now be the consumption, in the United Kingdom, of that apparently trifling article. In the three years ending with 1858, the average quantity of dry yeast imported amounted to 77,000 cwt. annually.

There is at present (1859) a praiseworthy attempt being made to bring about a change in the condition of the journeymen bakers employed in and near the metropolis. It has long been treated as a necessity that bakers should work at night, in order that families might have a supply of newly-baked loaves and rolls by the ordinary breakfast-time; and the arrangements between the employers and the employed bear immediate relation to this system. It begins now, however, to be disputed whether this necessity exists. The introduction of some of the recently-patented improvements, and a re-partition of the hours of working, would (it is contended by many well-informed persons) enable the working bakers to sleep at night, a regular number of hours, and out of the pernicious atmosphere of the bakehouse. An inquiry made by Dr. Guy, a few years ago, revealed a deplorable state of things, in reference to the daily life of the persons thus employed. A considerable impression was made on the public mind by these and similar revelations; and under the influence of this impression, the master-bakers of Edinburgh have one by one abandoned the system of night-work, and afforded to their journeymen the opportunity of obtaining rest at the same reasonable hours as other men. It is stated that the masters do not incur any commercial loss by the change, while the relations between them and their men are much more cordial and satisfactory than before. A communication to this effect has been transmitted from the master-bakers of Edinburgh to those of London. Glasgow and Belfast have also, to a great extent, adopted the new system; the inhabitants of those three cities appear to be satisfied with a bread-supply so managed that twelve hours journeymen's labour per day, from five o'clock in the morning till five in the evening, shall suffice; and there seems no good reason why the same plan, if judi-

ciously managed, or one nearly similar to it, should not be adopted in the metropolis.

BREAD, BEES, AND ALE, ASSIZE OF. [ASSIZE.]

BREAKWATER, a construction formed in the sea, or in any large body of water, for the purpose of destroying the action of the waves, and of thus securing the tranquillity of a roadstead. A breakwater, in fact, as the word has been of late years applied, differs from a pier or a jetty, inasmuch as it serves to protect a roadstead, and is formed in deep water, without any connexion with the shore; whereas piers or jetties only shelter closed basins, and are joined to the main land.

The engineers of antiquity executed, during the prosperous days of the Roman empire, some remarkable works of the nature of breakwaters, as we understand the term; and the entrances to the ports of Ostia and of Antium were protected by artificial islands, formed so as to break the force of the waves driving against them. It was not however until the latter end of the 18th century that modern engineers undertook any great work of this description. At that period the French government commenced the execution of the breakwater at Cherbourg; and subsequently similar operations have been carried on at Plymouth, Cette, the mouth of the Delaware, in Lake Erie at Buffalo, and at Portland, Dorsetshire. As the construction of the breakwater at Cherbourg was attended with the greatest difficulties, and has been studied more carefully than any of the analogous works, it will be noticed a little more in detail.

The breakwater of Cherbourg consists, at the present day, of a mass of rubble stone, cast into the water and allowed to assume its own natural outline; it is 12,356 English feet long, and in plan it presents the form of a species of chevron, whose arms are of unequal length, and which presents towards the open sea an obtuse angle at the summit, of 169° . The depth of water in this part of the roads is 61 feet at low water of average spring tides, and the width of the base is about 298 English feet; its transverse section may be described generally as follows: From the base to the level of about 22 feet below high-water line of spring tides, the slope on the land side is in the ratio of 1 in base to 1 in height (1 to 1); the top of the mass has then a much more gentle inclination, for in a width of $19\frac{1}{2}$ feet its inner summit attains the height of $15\frac{3}{4}$ feet below the said high-water line, or the slope is in fact, nearly 3 to 1. At this level the slope stops against a wall, almost vertical, which rises to 7 feet above the high-water, or datum line, and is crowned by a platform of about 21 feet in width, beyond which there is a solid granite parapet 8 feet wide and 5 feet high towards the sea. The outer line of this parapet is itself in continuation with the sea face of the wall, forming in fact the crown of the breakwater; and the wall is built of course granite ashlar, laid with the greatest care, and composed of the best materials, upon a general bed of hydraulic concrete 5 feet thick, extending over the loose rubble walling, at a level of 29 feet below datum. Beyond the edge of the masonry which protects the foot of the vertical wall, the slope assumed by the loose rubble, towards the open sea, is 1 in 10, until it reaches the depth of about 47 feet below datum; and from that level to the base the sea slope is about in the ratio of $1\frac{1}{2}$ to 1. It was found that the small stones at the foot of the vertical wall were very much disturbed by the movement of the waves; but this inconvenience has been of late materially obviated by covering the fore slope of the breakwater with huge artificial blocks of rubble masonry, set in Portland cement. The area sheltered by this gigantic structure is not less than 1926 acres nearly; but only about one-third of this area has a depth of 26 feet at low water of spring tides. At the bottom of the roads thus artificially protected are the military and the commercial ports of Cherbourg.

Fig. 1.—Cherbourg.

The works for the construction of the Cherbourg breakwater were commenced about 1783, by De Cessart, under the government of Louis XVI.; and they have been carried on with various success and upon various plans, by all the governments of France, until in the year 1853 the whole of the substructure was completed to such an extent as to allow the commencement of the fortifications proposed to be erected. It is estimated that the total cost up to 1853 was not less than 2,682,491*l.* sterling.

Plymouth breakwater is formed in a bay which is naturally more sheltered than the comparatively speaking open roadstead of Cherbourg; and its construction was favoured by the existence of some natural reefs upon the direction proposed to be adopted: nevertheless there was great boldness in its design, and the rapidity of its execution contrasts markedly with the slow progress of its great prototype. The plan of the Plymouth breakwater consists of a principal rectilinear mass with two return arms, forming with the centre body obtuse

angles towards the sea of about 135° ; the length of the centre body is about 1000 yards, and that of each of the arms about 350 yards; or in other words, the length of this work is only 5100 feet, whilst that of the Cherbourg breakwater is 12,356 feet. A surface of about 1120 acres is protected by the work executed at Plymouth.

Fig. 2.—Plymouth.

Originally it was intended to make the top of the breakwater only 11 yards wide, and the bottom 55 yards wide; but during the execution of the work, those dimensions were respectively increased to 15 yards and 133 yards. At the level of low water of spring tides, a set-off of about 22 yards in width is formed; and the sea slope from this point upwards is paved with very large stones, bedded in Roman cement; and the paving has been continued below low water line by means of the diving-bell. The height of the crown of the Plymouth breakwater is only 2 feet above the level of the high spring tides; whilst the height of the parapet of the vertical wall of the *digue* at Cherbourg is at least 12 feet above this line. The questions connected with the outlines of the respective works in the zones exposed to the action of storms will be noticed hereafter.

The Delaware and the Cette breakwaters do not exemplify any particular principle, nor do they illustrate any peculiar mode of construction, so that it may suffice to say that the former is about 1000 yards long, measuring upon the line of high water. Its slope towards the harbour is about 1 to 1; and the top, which finishes at about 5 feet 4 inches above the level of the highest spring tides, is about 30 feet wide. The outer slope is carried down, with an inclination of 3 base to 1 height, to a depth of about 19 feet below low water of spring tides,

Fig. 3.—Delaware.

Fig. 4.—Cette.

and, from thence to the bottom, the inclination is only as 1 to 1. The breakwater at Cette is principally remarkable on account of the great height to which the mass of masonry is carried above the high-water line; this is not less than 19 feet; and perhaps also the cubical contents of the transverse section may be cited as being worthy of remark. The total depth of water is only 24 feet in this part of the Mediterranean, but the width of the foot of the Cette breakwater is not less than 254 feet; its total length is about 514 yards, and the outline on plan is convex towards the open sea. The breakwater at Buffalo, in the state of New York and in Lake Erie, is constructed with nearly as much solidity as analogous structures in the ocean. It is, however,

Fig. 5.—Buffalo.

made with a vertical face towards the shore, and at about 5 feet above the water-line there is a platform 18 feet wide; upon this a wall is erected 5 feet high and 15 feet wide, from the outer edge of which the rubble masonry is carried with a slope of 3 to 1 to the shore of the lake.

The Portland breakwater is being constructed upon precisely the same principles as that of Plymouth; and it is therefore only remarkable on account of the mechanical contrivances adopted in the course of its execution.

There have been submitted to the public, of late years, a great number of schemes for forming floating breakwaters, wave screens, or for employing some more economical system than that of creating, as it were, artificial islands. But the marked failures of these ingenious contrivances have been so notorious, that it would be unnecessary here to discuss any of them. The attention of engineers charged with the execution of such works is, in fact, now exclusively directed to the

means of transporting the materials to the place of deposit, rapidly and economically; and to the various modes of terminating the exposed surfaces. Of course local circumstances will affect the first of these branches of inquiry; for the conditions which have allowed the use of locomotive power in the case of Portland, were totally wanting at either Cete, or at Cherbourg. But the question of the mode of terminating a breakwater, that is to say, whether it should finish with a long, gentle, paved slope as at Plymouth originally, or with an upright wall as at Cherbourg, is of a far more general nature, and has given rise to much discussion in the scientific and practical world. It certainly appears that the long slopes are less exposed to be injured by the direct action of the sea than are the upright walls; but it is equally certain that the latter offer a more direct resistance, and that they more effectually destroy the agitation and undulation of the sea; so that even if they should be rather more costly in their erection and maintenance, they are at the same time more effectual. In the case of the Plymouth breakwater, for instance, the waves occasionally have broken over the top, and have produced a considerable agitation in the inner roads; whilst at Cherbourg all their effect is destroyed by the wall. At Cherbourg, however, the descending motion of the return wave is materially interfered with, in consequence of the peculiar section presented by the wall; for the vertical wall at the top of the long slope transforms the descending into a horizontal motion, whose action is highly dangerous to the stability of the wall itself. It is also found that large blocks of stone are moved by the force of the waves from the fore slope of the Cherbourg breakwater, and that they are driven with great force against the outer face of the vertical wall; whilst the waves upon the Plymouth breakwater, from the fact of their not meeting any direct resistance, break upon its fore slope in precisely the same manner they would do upon a natural shore, and with a considerably reduced violence. It is true that in consequence of the particular section given to this Plymouth breakwater, the waves acquire an increased horizontal motion; but as the top is made as smooth as possible, there are no salient points able to attract the destructive action of the sea. Notwithstanding all the precautions taken at Plymouth, however, the repairs of that work are of a very costly, and unfortunately of a permanently recurring character; and the results of the practical experience, afforded by the action of storms upon works of this description, certainly at present must be considered to have shown that it is preferable at once to oppose to the waves a resistance able to annihilate their onward motion, than to endeavour gradually to destroy it. The worst effects observed at Cherbourg have arisen from the combination of the two systems; that is to say, from the erection of a vertical wall on the top of a long slope; and it is on this account that it has been necessary to adopt the extraordinary precautions lately taken for the purpose of defending the foot of the former. Practically it may be considered to be demonstrated that the most effective, because most economical and permanent, method of destroying the violent action of storm-waves, is to oppose to them an upright wall of such materials, and so constructed, as to offer a resistance considerably in excess of their effort. This effort was calculated by M. Duparc, one of the most distinguished engineers employed on the Cherbourg breakwater, at from 6100 to 8100 lbs. per yard superficial; and he therefore made the mass of his wall such as to offer a resistance equal to about 32,000 lbs. per yard superficial, to an effort tending to overthrow it; and to about 24,000 lbs. per yard superficial to an effort tending to make it move horizontally. The effort of the sea upon this structure has been found to be considerably in excess of the above calculation; but hitherto its powers of resistance have sufficed. The form and dimensions given to the enormous jetties of Dover, it may be here observed, seem to be as satisfactory as those of any analogous work in existence.

The reader is referred, for further information, to the description of the 'Travaux d'Achevement de la Digue de Cherbourg,' par M. Bonnin, 4to. Paris, 1857; Rennie's 'Treatise on the Formation of Harbours,' 2 vols. fol. Lond. 1852; the Parliamentary Reports upon the Harbours of Refuge, &c.

BREANE ($C_{40}H_{32}O_2$?). One of the constituents of Icica resin. It crystallises in radiated, colourless, and tasteless needles, which are quite neutral, insoluble in water and alkalies, almost insoluble in cold alcohol, but soluble in ether. It is fusible by heat, but cannot be distilled without decomposition.

BREAST, DISEASES OF. The mammary gland, especially in the female, is liable to various diseases, requiring the attention of the medical man.

Irritable Mamma. In both married and unmarried females the breast is liable to irritation from sympathy with other parts of the system. In these cases there is often great pain and uneasiness in the breast, and the whole system suffers more or less. There is no inflammation, and no swelling or external alteration of the mamma. The pain is sometimes intermittent or periodic, similar to neuralgia. When the general health is affected this must be attended to. Opium and hemlock may be employed internally, and nitrate of silver, belladonna, and aconite, have been recommended externally.

Mammitis. Inflammation, acute and chronic, of the substance of the mamma is not an unfrequent disease. It comes on from exposure to cold or a blow, or during the period of lactation. The pain is intense; the breasts are swollen, and tender to the touch. From the first there

is a tendency to suppuration. The secretion of milk is perverted and arrested. In the treatment leeches and warm fomentations and poultices should be applied to the breast. The bowels should be kept open, and the fever subdued. When matter forms it should be early evacuated. A chronic inflammation is sometimes observed. When this is the case stimulant applications to the breast will be found useful. Where this is attended with abscess it should be opened, so as to give free exit to the pus, and pressure applied.

Tumours of the Breast. The breast is subject to various kinds of partial and general enlargement. The "chronic mammary tumour" of Sir Astley Cooper consists of a partial hypertrophy of the gland. Enlargement of the whole gland also frequently takes place. These enlargements may be got rid of by pressure and treatment of the general health. The lactiferous ducts are sometimes blocked up, so as to produce distension, and an enlargement called *lacteal tumour*. Puncturing the enlarged tube and keeping it open will cure this form of tumour. The breast is also liable to fatty tumours, fibrous tumours, cystic sarcoma, hydatids, and malignant tumours. In many of these cases it becomes necessary to remove the breast. This is done in the following manner: "The patient having been placed recumbent, and duly anæsthetised, the arm on the affected side is raised and held by an assistant, so as to stretch the pectoralis major and facilitate incision. The knife is entered in the axillary aspect of the tumour in a line with the mamilla, and is moved in a semi-elliptical direction towards the opposite point; a similar proceeding is adopted—above or below, as the case may be—to complete the ellipse, and the size of this space necessarily varies according to the extent to which the integument seems to be involved, and according to the natural laxity of the parts. It is a fault to take away an undue amount of sound textures, so that difficulty is experienced in effecting and maintaining apposition of the wound; but it is a worse error to leave tainted parts, whereby reproduction of the disease cannot fail speedily to ensue. It is well to make the lower incision first, otherwise its course and position are apt to be uncertain under the irrigation of blood. Then on each aspect the knife is sloped through the subcutaneous part; and regular dissection is proceeded with from the axilla downwards, dividing the principal vessels and nerves at once, and so rendering the subsequent steps of the operation comparatively bloodless and free from pain. The diseased mass, with its border of comparatively sound tissue, in the case of malignant tumour, having been removed, is carefully examined on every aspect by both sight and touch; and, if need be, the knife is re-applied where thorough removal is not assuredly apparent. The vessels having been secured, the wound is brought together and treated in the ordinary way."

Much has been recently said of the removal of malignant tumours, especially of the breast, by means of escharotics. It is always difficult to decide exactly as to whether a tumour is malignant; and from all that has hitherto been made known of these formations, it would appear that, if they are cured by general or local treatment, the inference is that they were not malignant. With regard to general treatment, the evidence is very decisive that we possess no internal remedy that has any known influence over the progress of those tumours which are truly malignant. A recent American writer has professed to remove cancerous ulcers by a general and local treatment, which has been witnessed and reported on in this country. The cases referred to were treated at the Middlesex Hospital. The general treatment consisted in the administration of iodide of arsenic and the *Sanguinaria Canadensis*. The local treatment consisted in the application of the *Sanguinaria* and chloride of zinc. The method employed was to make a decoction of the *sanguinaria*, and, with an equal quantity of the chloride of zinc, to make the whole into a paste with common flour. This paste was applied directly to ulcerated cancers; and, where the skin was unbroken, nitric acid was first employed to produce an eschar. After this process incisions were made into the tumour, and the paste was inserted into the incisions on pieces of calico. This was continued from two to seven weeks, till the whole depth of the tumour was penetrated and removed. When this was effected the application of the paste was discontinued, and the wound allowed to get well. The *Sanguinaria* seems to exert no effect in this treatment, and its consideration may be altogether set aside. The following passage concludes the report of the surgical staff of the Middlesex Hospital on this mode of treating malignant tumours:—

"The last peculiarity of this treatment is the practice of incisions; and we are of opinion that this is its only but its very great merit. The *Sanguinaria* is inert; the chloride of zinc paste was known before; but the incisions constitute a new feature in the treatment of cancerous tumours for which we find no parallel in the writings of the past, or in the practice of present surgeons. Cancer in its constitutional nature remains as ruthless and as unassailable as ever."

BREAST-PLATE. [ARMOUR.]

BREAST-WORK is a term applied to any hastily constructed field-work, being sometimes not sufficiently high to necessitate a banquette. When the work has its surfaces carefully formed, and revetted or covered with sods, particularly when it is elevated on the rampart of a fortress, or constitutes a considerable field-fort, it is always denominated a parapet—the word *breast-work* being chiefly applied to a rudely formed mass of earth thrown up to cover the troops stationed on any exposed part of a field of battle, or doing duty as an outpost of the

army; or to the *gabionnade*, that is, the row of gabions placed on end and filled with earth, which the sappers construct for the protection of the troops in the trenches, or on the breach which is made in a rampart. A breast-work, however, differs from an epaulement, which is also a mass of earth or other material raised to cover troops or artillery when in situations exposed to the fire of the enemy, in being constructed to fire from.

The intrenchments with which the Greeks and Romans protected the ground occupied by their armies were breast-works, which in wooded countries frequently consisted merely of felled trees; and in other circumstances were formed of earth protected by palisades, or by the interwoven branches of trees planted on the top of the bank of earth. The same denomination might be applied to the continuous lines which were formerly raised for the protection of armies; but as these are not now recommended by engineers, and as instead of them a number of separate redoubts are usually formed at intervals from each other to contain artillery, the word breast-work is little used, the protecting masses of earth generally receiving the name which is given to those which crown the ramparts of a permanent fortification.

BREATH FIGURES. If we write with a blunt wooden point upon a clean surface of glass or other polished material, and then breathe upon it, the characters will become visible: or if we first breathe upon the glass, and then trace some characters with a blunt point in the midst of the breath, the characters can be brought out again by breathing on the surface. Hence the Germans call the figures which are produced by the breath, *Hauchfiguren*; while the French philosophers term them *figures roriques*, or *roric* figures, from the Latin for "dew," *ros*, gen. *roris*.

These figures, which may be produced in a variety of ways, first excited attention in the year 1842, when Moser of Königsberg announced to Humboldt the remarkable proposition that "if any two bodies be brought sufficiently near together, and face to face, one of them impresses its image on the other." Thus, if a coin be left for some time upon a polished metal plate, the plate will retain an impression of the coin, which may be made visible by exposure to the vapour of water, mercury, iodine, &c. So, also, if a polished plate of silver, or of copper, be covered by, but not in contact with, a blackened glass plate, with some characters scratched on it through the opaque black, and so exposed for some days to the sunshine, the metal plate will be impressed with the characters, which will make themselves visible by exposure to vapour. Experiments of this kind may be varied to any extent; and no sooner did Moser call attention to them, than other persons were ready with similar examples. Thus, Rauch, the sculptor, stated that the glass used to protect a print after Raphael, although not in contact with it, had received an impression of the print on its inner surface. It was found on inquiry that this fact was well known to persons accustomed to frame prints.* Breguet, the celebrated Parisian watchmaker, stated a fact that had long been known in his workshop; namely, that the inscription and letters on the back of the inner cases of his watches were found repeated on the inside of the outer cases, although the two surfaces were not in contact. It was also noticed by engineers, &c., that the parts of machines in contact or near together easily and quickly impress themselves upon each other.

It was also found that very perfect impressions of objects could be produced by means of electricity. Thus, if a coin be placed upon a glass plate which is supported by a metal one, and a stream of sparks from the knob of the prime conductor be thrown upon the coin, about a hundred turns of the machine will suffice to impress the coin very perfectly upon the glass. On throwing off the coin, nothing is visible until the breath be projected upon the plate, when the image and superscription, the milling, and other minute details of the coin instantly appear. In producing these impressions on metal, it is necessary to separate the coin from the metal by means of a thin plate of mica, or of glass, or oiled paper. The impression is produced after about fifteen or twenty turns of the machine, but by continuing the action on a polished silver plate a permanent impression has been made as distinctly as if it had been etched by aqua fortis. As many as one thousand turns of the machine are required for this effect, and it would be reasonable to suppose that nitric acid was actually formed, but Karsten, who first obtained electrical breath figures, was not able to detect the presence of any.

Moser explained the production of his figures, which could be formed in total darkness as well as in light, by referring them to the action of the most refrangible dark rays of the spectrum, considering that all

* While reading this proof we have received, from Professor George Wilson, of Edinburgh, the following remarkable case: "In connexion with electric images, I received yesterday two photographs, the peculiarities of which I shall try to explain. The wax-paper negative of a ship was laid in the usual way for printing, on a sheet of prepared paper, and below the latter intended to receive the positive copy, a sheet of ordinary letter post was laid to act as a packing in the printing-frame. The positive was duly taken, fixed, and laid aside. Some time after another negative, namely, of a sloop, was arranged as before, with a piece of positive paper next it, and for package, the same sheet of letter post as before. When the positive was removed, it had the sloop on one side, and the ship in addition on the other. In some strange way the letter post had received a latent image, I suppose, of its first neighbour, the ship, and transferred this to the back of its second neighbour the sloop! Fixing has dimmed the sharpness, but there they both are."

bodies radiate light even in the dark. Karsten's figures received a more satisfactory explanation from the experiments of Riess, who many years before had remarked that, on sending the discharge of an electric battery over the surface of glass or of mica, certain ramified figures were produced, which became visible by breathing on the plate. Now, it was observed by Riess, that different surfaces condense the breath in a very different manner; that a surface of mica which had been exposed for some time to the air, did not allow the moisture to condense in a continuous film, but that it formed a congeries of dew-drops with many breaks and interruptions; whereas, by splitting open the mica so as to obtain one of nature's clean surfaces, the vapour condensed in a continuous film or sheet of water. In the course of a short time, however, the new and chemically clean surface becomes covered with a film of matter chiefly organic, arising from motes floating in the air, dust, and moisture charged with the breath of animals sufficient to prevent the vapour of water from coming in contact with the surface, and explaining why vapour condenses in drops and not in a continuous film. Now, the action of the electricity is to burn off a portion of this film, which it does more or less according as the parts of the coin are more or less salient; so that, on throwing off the coin and breathing on the plate, the breath becomes condensed, and reflects the light differently in those parts of the plate which were nearest to the coin compared with the other and remoter portions. That this is the true explanation is evident from the fact, that the electrical breath figures cannot be produced on glass if the surface be made chemically clean by being boiled in nitric acid and washed in dilute ammonia; nor on platinum if that metal be made sufficiently clean to fire hydrogen gas.

This simple explanation is not however sufficient to account for all the varieties of roric figures. There must also be some molecular change induced in the plate itself, which, though quite invisible to the eye, nevertheless disposes the surface so as to make it catch the breath differently. Karsten states that eight or ten thin plates of glass superposed, will all receive the impression of a coin placed on the top plate and electrified; the impressions become fainter and fainter in descending, and at a certain depth disappear. This seems to be a case of molecular action in the lower plates not to be explained by the burning off of a portion of the film in the upper one. So, also, if we cover a polished surface, such as granite, with a perforated pattern or trellis-work, and expose it to the sun for half an hour, the vapour of water, or mercury, &c., will afterwards, when the perforated pattern is removed, make out the pattern with perfect distinctness. This molecular action is assisted by heat, as in the last experiment, and still more strikingly by placing a sovereign on a glass plate on the warm mantel-shelf, and leaving it there for half an hour. On throwing off the sovereign and exposing the glass to the vapour of mercury, the details of the coin are beautifully made out. In this case, the warmth streaming up through the glass is intercepted by the metal and reflected back again upon itself, and that differently by different parts of the coin, whereby a new arrangement of molecules is produced at the surface, and the vapour of mercury is caught and held with corresponding differences in different parts of the surface thus acted on, so that the light reflected by the vapour informs the eye of these differences, and thus makes out the image of the coin. We should be disposed to refer the impression to the action of radiant heat when the coin is not in contact with the plate, but suspended at a short distance over it. It requires in such case a longer time to produce the impression, but it is nevertheless made.

De la Rive and others, who contend for the electrical origin of roric figures, imagine that the surfaces, though not in contact, have electricity developed upon one of them at least, by the action of a moist atmosphere. It is stated also that the metals must be of different kinds, as in Mr. Hunt's experiment, in which a sovereign, a shilling, and a penny were placed on a copper plate, when the two former gave excellent images, and the penny a very slight one. It is stated that roric images cannot be produced on plates of gold and of platinum, nor on a surface that does not oxidise; also that in very pure water deprived of air, and also *in vacuo*, these images are formed either not at all, or but slightly. Many of these statements are the result of preconceived theory, in which there is an anxiety to explain the production of all roric figures by electricity; whereas, as there are many modes of producing these figures, so there are, in the wide diversity of nature's operations, several methods of explaining them.

Some remarkable roric figures may be produced on the surface of glass by any one who is in possession of a small electrical machine, a Leyden jar, and a discharging rod. Plates of crown glass about four inches square answer the purpose very well; they should be washed in soap and water, and carefully dried. The jar should be fully charged; and on discharging it, with a plate of glass interposed, the spark will pass to one of the edges of the plate, and turning round will proceed up the glass on the other side to the knob of the discharging rod. In this way the electricity traces a figure on both sides of the glass, and it becomes visible by breathing on the surface. The figure, on the side of the glass presented to the jar, which we may call the *positive* side, is much more developed than on the other, or *negative* side. The following engraving is a specimen of the figures thus produced. The various ramifications do not proceed from the trunk or course of the discharge, but the trunk proceeds from them. In fact, these minute and delicate branches are *feelers*, sent out to determine the line of

least resistance, and they mark themselves upon the glass before the principal discharge takes place. That such is the case is evident from

Positive side.

Negative side.

the fact, that if the plate be too large, or too thick, or the jar not fully charged, or the electricity deficient in tension, no disruptive discharge takes place, but the plate becomes covered with these ramifications, while the charge still remains in the jar. A corresponding action takes place in nature. Just before a ship has been struck by lightning, the people on board sometimes speak of the well-known electrical sensation as if a cobweb were being drawn over the face; they also hear a hissing roaring noise, and perceive brushes of light. These sensations are also sometimes experienced when, from some cause or other, no discharge takes place. This class of roric figures admirably illustrates the phenomena of lightning, or that form of discharge known as *ribbon* or *chain* lightning. It descends from the thunder-cloud to the earth in the same jagged trembling line as here represented, sometimes dividing into two or three main branches, and these bi-furcations or tri-furcations are often admirably produced on the glass plates. The writer of this article has made several attempts to render these figures permanently visible on the glass, but he has not yet succeeded in doing so. The vapour of mercury, &c., brings out only the principal lines of discharge; while a coating of collodion, candle-smoke, &c., does not receive the details of the impression. The discharge appears to produce some permanent change on the surface of the glass, so that while the breath is condensed on the portions unacted on, it does not condense on the parts occupied by the figure. When once the figure has been formed, it is difficult to get rid of it, the ordinary methods of washing and rubbing failing to do so effectually. There are many points connected with these figures which are still open to inquiry. It is curious also to notice the various modes in which the breath condenses on the plates, according to the temperature of the air and the amount of humidity or dryness, the tension of the electricity, and the state of health of the experimentalist. During the warm humid weather which occurred on certain days at the end of May and the beginning of June, 1859, it was almost impossible to produce these figures. Then again in breathing on the plates a quantity of organic matter is deposited, which varies with the kind of food, the time that it has been taken,

and the state of health of the individual. The breath moreover is differently deposited when projected by different individuals. The state of the breath is known to have a considerable influence in photography, and it has been noticed in other arts. In an old French treatise on Enamel Painting ('Dict. des Arts et Métiers,' Lyon, 1801), the artist is cautioned not to let any one approach his work who has been eating garlic or taking mercurial medicines.

BREATHING. [RESPIRATION.]

BREAST-WHEEL. [HYDRAULICS.]

BREEDING is the art of multiplying the domestic animals rapidly, and at the same time improving their qualities.

Any breed of animals will perpetuate itself, if a sufficiency of proper food be provided; and the varieties found in a wild state must depend in some degree on the climate and the products of the country in which they are found. Care and domestication also produce varieties, which are much more useful or profitable than the wild breeds; and in the selection of the best individuals to propagate a useful race, and in the rearing of the young, consists the art of the breeder.

Without entering into particulars, which vary with every species of animal, and with the different varieties of the same species, we shall lay down certain principles which experience has proved to be correct, and which being attended to will greatly promote the improvement of all the different animals usually bred for the use of man, whether for his sustenance or for his pleasure. The first thing which is to be kept in view is the chief purpose for which the animal is reared, whether for labour and to assist human strength, or for speed, to convey us rapidly from one place to another; whether merely for a supply of animal food, or to produce the raw materials of manufacture. In each of these cases distinct qualities are required; and it is seldom that two of these objects can be combined in the greatest perfection.

Having then determined the purpose for which any species of domestic animal is designed, every quality must be attended to which furthers this view; and, except under very peculiar circumstances, the animals intended to keep up the stock by their produce must be chosen with those qualities in the greatest perfection which are essential to the end. In all animals a perfect conformation of the bodily frame is essential to the due performance of the vital functions. The skeleton of the animal should therefore be as perfect as possible. The capacity of the chest, and the healthy nature of the lungs, are points which must never be overlooked, whatever may be the purpose for which the animal is bred; for although a defect may in some measure be counteracted by a judicious choice of the individual coupled with the defective animal, it is only where there is no alternative or choice that any defect in the bodily frame of an animal kept for breeding should be overlooked. In spite of every care, the defect will appear in the offspring; sometimes not till after several generations. If it were possible to find individuals without fault or defect, no price would be too great for them; and for those that have been carefully selected for several generations, it is real economy to give a very liberal price. In horses bred for racing or for the chase, experience has fully proved the truth of this rule; and no one who pretends to breed race-horses would breed from a mare which had a natural defect, or a horse whose whole pedigree was not free from fault. For mere swiftness the shape of the animal, whether horse or greyhound, must combine strength with great activity. The chest must be deep, the lungs free, and the digestive organs sound but small, to add as little weight to the body as is consistent with the healthy functions of nature. The legs should be long and slender, and the bones compact and strong; but the principal thing to be attended to is the courage, and no quality is so hereditary. A horse or hound of a good breed, if in health, will die of exertion sooner than give up the chase. Any defect in courage in an animal intended for great occasional exertion, renders him unfit to be selected to continue an improved breed; and whatever may be his pedigree he has degenerated.

With respect to animals whose strength and endurance are their most desirable qualities, a greater compactness of form is required, a greater capacity of the digestive organs, and, according to the climate to which they may be exposed, a more suitable covering. Whether it be to ward off cold or great heat, a thick covering of hair is equally serviceable in both cases. Hardiness of constitution is hereditary, like other qualities; and the manner in which the young are reared tends greatly to confirm or diminish this. An animal of which the breed originally came from a warm climate, like a tender exotic plant, wants artificial warmth for the healthy growth of its limbs; while the indigenous and more hardy breeds may be left exposed to the elements. An abundance of wholesome food and pure water is essential to the healthy state of every animal, as well as exercise proportioned to its strength. These are circumstances which it is obvious must be carefully attended to. There are others, the result of long experience, which are equally necessary to be known, but which are not so obvious. These vary according to the species and variety of the animals bred; and it is seldom that the same breeder is equally successful in rearing different species of animals.

In the animals selected to breed from there are *points*, as they are called, which are peculiar conformations, some of which are connected with the natural formation of the skeleton, and others appear to be the result of an association derived from the known qualities of certain

individuals, and of which no very good physiological account can be given. That high withers and a freely-moving shoulder-blade in a horse are connected with his speed is readily perceived, and that the length of the muscles of the quarter, and the manner of their insertion, should affect his power is equally evident; but it is not so apparent that the manner in which the ears are placed on the head, the shape of the nose or jaw, and the insertion of the tail higher or lower, has an important effect on the value of the animal, independently of any arbitrary idea of beauty. A breeder however who should not attend to these circumstances in the animals chosen to perpetuate the breed, would find to his cost that it is more than mere taste which has determined these points. It is the result of observation and experience that certain breeds are invariably distinguished by certain peculiarities, and that these are almost as invariably connected with good qualities, apparently quite independent of the parts on which these points appear.

There is an indication of the disposition of an animal in the eye, in the shape of the head, and in the manner in which it is carried, which seldom deceives an experienced judge. He will not risk introducing a vicious or sulky disposition into his breed, which might counterbalance all the good qualities the animal might possess, and introduce a greater hereditary fault than any imperfection of form.

But nothing is so deceitful as the prejudices which exist with respect to peculiarities and colours. In some countries no ox or cow would be thought good of its kind that was not red or brown without spots; in others, a certain portion of white is essential. In Suffolk, no cart-horse is prized which is not chestnut; in Northamptonshire, he must be black; in Yorkshire, brown or bay. This is owing to the common colour of the breed most esteemed in each country. In Belgium, whence the Suffolk breed originally came, but which has degenerated in its native country, a chestnut horse, with a white mane and tail, as well as a red cow, are despised. Here the reason of the prejudice is the association of the colour with some defect, and those who breed for profit by sale must be ruled by the taste of their customers. The rational mode of proceeding is, to be well acquainted with the anatomy of the kind of animal which we make the subject of our attention; to learn by experience what are the peculiar qualities of the different breeds, distinguished by any particular feature, and whether these qualities have any apparent connection with the peculiarity in make or colour. We may then be guided by the knowledge thus acquired in our choice of individuals, to perpetuate the breed, and not only preserve the useful qualities which they already possess, but gradually improve them. No greater mistake can be committed than that of making what are called violent crosses, such as coupling a very spirited male with a sluggish female, an animal with large bones with one of very slender make, a long-limbed animal with a compact one. By such crosses the first produce has often appeared much improved; but nature is not to be forced, and if the breed is continued, innumerable deformities and defects are certain to follow. The safe way is to choose the animals as nearly alike in their general qualities as possible, taking care that where there is a defect in one it exist not in the other, which would infallibly perpetuate it. A defect can never be remedied by means of another of an opposite kind, but, by great attention, it may be diminished gradually, and at last disappear entirely. This refers however to defects, not to peculiar qualities. Cows, for example, may produce either milk or fat in abundance from similar food; and a species of cow, which secretes too much fat, so as to be deficient in the milk necessary to rear the calf, may be improved by selecting individuals which give more milk, and by crossing the breed with these; but we must be careful not to choose individuals which differ much in shape from the breed to be improved. A cross between a Herefordshire cow and an Alderney bull might possibly produce a good cow, but the breed of this cow would probably be of inferior quality, whether for fattening or for the dairy, and nothing but ill-formed cows, deficient in milk, and slow-feeding oxen, are likely to result from it. Every attempt to unite opposite qualities is generally attended with a bad result. If a breed has too great an aptitude to fatten, so as to endanger the fecundity of the mother or the health of the offspring, the only remedy is to diminish the food; and if, on the other hand, a difficulty is found in fattening cows which are of a peculiarly good breed for the dairy, such as the Alderney cows and other small breeds, the loss on the old cow sold half fat will have been amply repaid by the milk she has given; and the bull-calves which are not wanted to rear for bulls, if they are not profitable to fatten as oxen, must be fatted off young and sold for veal. But it is not a necessary consequence of an abundant produce of milk, that the cow, when dry, will not fatten readily; although a great propensity to fatten renders the breed less fit for the dairy. The Ayrshire, which are good milkers, fatten well when dry, and the oxen of that breed are as kind feeders as any.

Many breeders have an idea that coupling animals which are nearly allied in blood produces a weak race; others consider it as a prejudice, and among those who held the latter opinion was the famous breeder Bakewell. Without deciding this point, we should recommend avoiding too near a relationship, provided individuals equally perfect can be found of the same breed more distantly related. Every individual has some peculiar defect, and his descendants have a tendency to this defect. If two immediate descendants are coupled, this defect will probably be confirmed; whereas, by uniting the descendants of

different individuals, the defect of either of the parents may never break out. But sooner than retrograde by coupling an inferior animal with one in an improved state, we should not hesitate to risk the consequences supposed to arise from what is called breeding in and in, that is, coupling animals nearly related in blood, especially if only on one side, such as the produce of the same male by different females, or of a female by different sires. The qualities which distinguish animals in which the muscles and bones are required to be much exercised, as dogs, horses, and working oxen, are very different from those of animals destined to accumulate mere tender flesh and fat for human food. In the former there must be spirit, activity, and quick digestion; in the latter, indolence and proneness to sleep are advantageous. In the first, the lungs must play with ease, and the muscles be strong, and not encumbered with fat; in the second, the lungs must be sound, as they are essential to all the secretions, and the digestive power must be good, but slow. The food must not be accelerated through the bowels by exercise, but the absorbent vessels of the intestines must draw all the nourishment from the digested food. The more the muscles are impeded with fat, the better the animal will repay the food given him. To choose an animal to breed from, whose produce shall get fat readily, we must attend to this part of the constitution, and care little about spirit and activity. The tendency to secrete bone, and those parts which are called offal by the butchers, as being of inferior value, is a defect. Good flesh and fat are the great objects.

The manner in which the more solid parts of the body are formed, and the greater consumption of food, in proportion to the increase of weight, which takes place in young animals, while bones and horns are growing, prove that it is much more expensive to produce bone than flesh, and muscular fibre than fat. Hence it is evident that the greater profit is in fattening animals that have finished their growth; and also that there is a superiority in those breeds which have small bones and no horns. This is an important point to be attended to by a breeder, as is also the time when the bony secretion is completed. A breed of animals that will cease to grow, or have attained their full size of bone at an early age, will be much more profitable to the grazier than one of slower growth. It is in this respect chiefly that certain breeds of sheep and cattle are so far superior to others. The principles which apply to cattle are equally applicable, *mutatis mutandis*, to sheep. In no case are strong bones or horns of much importance to the sheep in its domestic state. The principal objects are wool and flesh, which appear to be dependent on distinct and perhaps incompatible qualities. The attempt to unite the two is perhaps the reason why the Spanish breed, which has been improved when transported into Saxony, has degenerated in England; so that even its crosses are not in repute. It is a matter of mere calculation, whether sheep kept for their wool chiefly are more profitable than those which give an increase of meat at the expense of the quality of the wool. A breeder of sheep who attends only to the quality of the wool, will not have his attention taken off from the main object by any deficiency in the carcase, or the disposition of the animal to increase in flesh and fat. It is possible that mixed breeds may be more profitable than the pure. Fine wool may not repay the breeder and rearer of sheep so well as moderate wool and good meat. But the principle we contend for is, that of producing the most perfect animal of any one variety existing, by correcting individual defects gradually, and avoiding fanciful crosses, which may destroy in one generation all the advantages obtained in a great many. Hence it is a matter of great importance to consider well the qualities of the individuals with which you begin your improvement, and to know that these qualities have existed in their progenitors, and are not merely accidental. If crossing appear necessary, let it be done very gradually and cautiously. No experienced breeder would ever expect to improve the fleece of a sheep of the Leicester breed or the carcase of the Merino by a direct cross between these two breeds. The offspring would most probably lose all the good qualities for which each breed is noted, and produce a mongrel breed worth little in comparison. But a cross of Merinos with South Downs, or Leicester with Cotswold, might produce new and useful breeds, and these, carefully selected, as has been done, have produced mixed breeds, which by great attention may become very valuable.

When it is determined what breed of animals you wish to perpetuate and improve, the individuals which are to be the parents of the stock cannot be too carefully selected. The more nearly they are alike in form, colour and exterior appearance, the more likely they are to produce a distinct race. They should neither be above nor under the usual size. They should be of such an age as to have entirely ceased growing, and be arrived at perfect maturity; and whatever may be their good qualities, they should not be selected, if they are the produce of very aged parents, at least on the female side.

In horses and horned cattle many breeders prefer a male rather less in size than the female, and pretend that the foetus has more room to develop its members in what they term a *roomy* female.* There may be some truth in this, but equality of size, or rather the due proportion established in nature, seems most likely to produce a well-formed offspring. Any considerable deviation from this is generally attended with defect. Nothing is more common than for a country gentleman who has a useful favourite mare, not particularly well bred, when any

* See Communications to the Board of Agriculture, by Mr. Cline, vol. iv.

accident has rendered her unfit for work, to have her covered by some very high-bred stallion, expecting to have a very superior foal. Sometimes this succeeds, but in general it ends in disappointment, especially if the mare be small. A much more certain way is to choose a half-bred stallion, nearly of the size of the mare, and having those good points which the mare already possesses. In this case there is every probability of rearing a well-proportioned and useful animal, instead of a *cross made* one, as the breeders call them, probably from the very circumstance of these *crosses* not succeeding in general. We advert to this as a fact which many of our readers may know from experience.

To give in a few words the rules which result from what we have briefly stated:—

Choose the kind of animal you wish to breed from, having distinguishing qualities; keep these constantly in view and reject all individuals in which they are not as perfect at least as in the parents. Select the most perfect forms and let the defects be corrected gradually. Have patience and perseverance and avoid all attempts at any sudden alteration by bold crosses. If possible, breed two or more families of the same kind, keeping them distinct, and only occasionally crossing the one with the other. In this manner a very improved breed may be produced. The nearer you approach to perfection the more difficult will be the selection, and the greater the danger of retrograding. Hence in very highly bred stocks it is often almost impossible to keep up the perfection of the breed, and a fluctuation in the quality of the produce will take place. The more improved the breed is, therefore, the greater attention must be paid in the selection of those which are to continue it. And for want of this, almost every breed, however reputed it may have been at one time, gradually degenerates, and loses its great superiority.

We add on this subject the following passages extracted from a lecture by Mr. S. Evans, M.R.C.V.S., lately (April, 1859) delivered before the Wenlock Farmer's Club. He said:

"The first great law of nature in breeding is, that like should produce like; but it must be accompanied in our mind with another law, the law of variation. One of the causes of variation is what is called 'breeding back.' It is often a source of disappointment to the breeder that when he puts a well-formed female to a well-formed male, he gets an ill-formed colt or calf, and of quite a different colour to what he expected. If you inquire into the pedigree of the parents you will find the child answering in every respect to the description of an ancestor. It is this that makes many say that horse-breeding is a lottery. However, if you breed properly you have little to fear. Pure and thorough-bred animals comparatively seldom breed back, or disappoint their owners in doing so. By thorough-bred is meant those whose ancestors were for a long time of the same shape, and adapted for the same purpose as themselves. The more the animals have been crossed the more subject are they to breed back, and the more the difference of shape in crossing the more likely is breeding back to prove a disappointment. This should make you very careful in breeding stock, and to ascertain that not only the sire and dam are free from spavin, curbs, &c., but that their ancestors were not subject to any hereditary affection, and not only that they were free from hereditary evils, but that they possess the same good qualities, and are adapted for the same purpose as themselves. Now comes the vexed question, Which has the predominating influence on the progeny, the male or the female parent? If both parents join to form the child, does one parent give one group of organs and the other parent another group; or do both give all?

"It is not fair to look at one set of facts alone, and shut our eyes to others. It is by an impartial survey of them all that we get the truth. There is an able article upon this subject in the 'Westminster Review,' which says that both parents are always represented in the offspring; and although the male influence is sometimes seen to predominate in one direction, and the female influence in another, yet this direction is by no means constant, is often reversed, and admits of no absolute reduction to a known formula.

"It is a common but silly question, Which breed of animals is the best for the farmer? Some advocate short-horns, others advocate the long-horns.

"That breed of animals is the most profitable which is best adapted for that particular locality. One class does better on upland, others on lowland; some do better grassing, others do better housed. It also depends upon the demand of the neighbouring markets. In some parts cheese-making pays best; in other parts milk; in other parts meat, &c. In some districts it pays better to breed draught horses, in others hackneys and hunters, in others racehorses, in others ponies, &c. Every breed has its own peculiar conformation, and that conformation you will find upon close investigation to be peculiarly well adapted for a particular purpose; and when you adopt and cultivate a certain breed, you must always keep that purpose and that conformation steadily in view. If you lose the conformation, you will soon lose the purpose. For instance, we may divide cattle into two primary classes: 1, for fattening and arriving at early maturity; 2, for dairy purposes. We may also divide horses into two primary classes: to carry weights on the back, and go fast; and to draw weights after them. It is evident that they are destined for very different purposes, and must set to work in a very different manner. There is a peculiar

shape adapted to perform any particular work, and it is essential that the young man should make himself thoroughly acquainted with those before he can be expected to be a successful breeder. Starting then upon the great law of nature, that like produces like, and being prepared to guard against variations by breeding from animals of the same sort, &c., breeding good stock becomes a simple matter of course. First ascertain what animals your land is best adapted for. Secondly, what have the readiest sale in your markets. Thirdly, having decided upon the purpose of your animal, study the best shape and conformation calculated to attain your object in a most perfect manner; if you wish to breed fat stock, study the shape most disposed to lay on fat with the least food, and to arrive at early maturity; if you wish to breed milk cows, study the proper shapes for them; if you breed horses, study the proper shapes to perform their various duties. Fourthly, don't breed from an animal, whether male or female, whose shape is not well adapted to perform the work it is intended for: let them be of the most perfect shape you can get of their kind. Fifthly, being acquainted with the law of breeding back, you will not be satisfied unless their ancestors were also of the same sort, and equally good; in fact, thorough-bred, and free from hereditary evils. Remember the term thorough-bred may be equally well applied to the cart-horse, or hunter, or pony, or carriage-horse, &c. It means those whose pedigree for a considerable time back were of the same class, and adapted for the same purpose as themselves. Unless you commence to establish a new breed, you should never breed from a half-bred animal. Let them all be castrated. There is too much risk connected with it; it is based upon a wrong principle; you should carry the right principle out thoroughly. Why should you breed from a half-bred mare more than from a half-bred cow? Some may say that you have no pure or thorough breeds, except racers; therefore you ask how can you avoid crossing. Well, 'It is never too late to mend.' By breeding exclusively from animals of the same shape, and, therefore, adapted for the same purpose, with careful attention to pedigree, you may easily establish a breed for any purpose whatever."

As every farmer and occupier of land is more or less a breeder, if he be only a breeder of pigs, these observations may be useful. In the articles on each particular species of animal, these general principles are applied and more particular directions are given.

BREHON LAWS. The ancient laws of the Irish, so called from being expounded by judges, named in the Irish language *Breitheamhuin*, or Brehons. *Feineachas* however and *Breitha-neimeadh*, words said to signify respectively ancient laws and sacred ordinations, are the terms commonly applied to the collection of these writings by the native writers.

Prior to the Anglo-Norman invasion, Ireland was wholly governed by the Brehon law; and, notwithstanding the statements of Spenser, Sir John Davies, Cox, and others, that this was an unwritten and barbarous code, there is abundant evidence to prove that some of the collections of the *Breitha-neimeadh* are of equal antiquity with the oldest manuscripts of Irish history, whether civil or ecclesiastical, an antiquity which carries us safely back to the earlier ages of the Christian era. The extant collections are numerous and authentic, but the labour of translating and methodising them, though a most desirable service, has been long neglected. It is, however, now entrusted to the very competent hands of Dr. John O'Donovan and Mr. Eugene Curry, for whose labours during the last few years the British parliament have voted considerable sums of money; and, when completed, the results are to be printed. Nothing has yet appeared, but still we are not altogether ignorant of what the Brehon laws were. The 'Encyclopædia Britannica,' under the head 'Brehon Laws,' published in 1854, says, "there are, it is said, in Ireland, ancient MSS., the publication of which would throw light on this curious and interesting subject. Till such elucidation be afforded, of which some prospect is held out, it were useless to hazard opinions on the character and value of the Brehon Laws as a system of jurisprudence." The "it is said" is somewhat disingenuous, when an elaborate article on the subject had appeared in the 'Penny Cyclopædia' in 1836. That article we now reproduce. Within our limits, of course, it is not possible to do more than give such an outline of the social system of the old Irish under these laws as their available fragments, compared with the general history of the country, would point out to the reader of the various accessible authorities on the subject.

The present division of Ireland into provinces, counties, baronies, and townlands, would appear to correspond pretty nearly with the old territorial distinctions of minor kingships, lordships of countries, chiefries of clans, and presidencies (if we may use the term) of villages; all subject to the dominion of the *Ard Righ*, or supreme king, and tributary, one to another, among themselves.

The law governing this community is distinguishable into the common and, so to speak, the statute law. And, first, as to the common law, or immemorial custom of the country, our information is necessarily scanty, as being derived chiefly from the reference made to such usages in the remaining fragments of the written law; for at this day there remains scarce any oral tradition available on this subject in Ireland. The constitution of the bulk of society in ancient Ireland was patriarchal and pastoral. By the common law of the tribes, the ground belonging to each seems to have been divided into common pasture lands, common tillage lands, private demesne lands, and

demesne lands of the tribe. Each man of the tribe had then the right to pasture as many cattle as he possessed on these common grazing lands; and in proportion to the number of cattle thus pastured by each was the share of the common tillage lands assigned to him on the annual partition or hotch-potch of the lands. The private demesne lands were the distinct property of individuals who were entitled to acquire and transmit such possessions by certain qualifications not very clearly explained. The demesne lands of the tribe were set apart for the maintenance of the chief, the chief elect, the bard, doctor, and brehon.

With regard to the nature of the property enjoyed in these several estates, the tribe at large possessed what is called the allodial or original indefeasible property in all the lands, and could not be ejected out of them in consequence of any arrears of tribute, inasmuch as the superior lord lifted only a proportion of the increase of stock upon the pastures, and was bound to take the same away at certain seasons; this rent was precisely a lay tithe, being one-tenth of the increase. As to the common tillage lands, every member of the tribe possessed a life interest in them, proportioned to his stock in cattle. In the private demesne lands individuals had a permanent inheritable interest. In his separate portion of the demesne lands of the tribe, the chief had a life interest, of which the reversion lay with the tanist, that is, the *second man*, or chief elect, and in like manner the tanist, bard, &c., possessed life interests in their several portions.

The personal distinctions of the tribe, corresponding to the above territorial divisions, were, so far as can be gathered from the very confused authorities on this head, the *In-finné*, holders in common, and the *Dathaig-finné*, those individuals alluded to above who were entitled to separate inheritable possessions. The *In-finné*, or commonalty of this pastoral corporation, appear to have been of one rank; but the *Dathaig-finné* were divided into several classes, of which the three most intelligible were, the *Deirbh-finné*, or class, as the commentators explain it, nearest the succession, who had the right to inherit the whole patrimony of their kin without deduction; the *Gall-finné*, who inherited three-fourths of their patrimonial estates; and the *Iar-finné*, whose right of inheritance extended to only one-fourth of the property left by their relations. These privileged classes were in every tribe limited in number; but it does not exactly appear what was the qualification for admission, or the rule of exclusion, or whether the *Deirbh-finné*, for instance, became disqualified on the election of a tanist less nearly related to them than to others, although it is evident that a man might rise from the condition of a tenant of common tillage to that of a freeholder, or *vice versâ*, descend from the higher class to the lower. As to the chief himself, he was usually elected before the death of his predecessor; and the rule seems to have been invariably, that the eldest of the candidates, if not incapacitated by age or infirmity, should have the preference, the brother being commonly chosen instead of the son, and the son rather than the nephew. His revenue arose, as has been said, from the tenths of the increase of cattle, and from the revenues of his demesne lands. In addition, he had certain claims of entertainment for himself and household at stated times in the houses of his tenants, in the same manner as his superiors, at certain seasons, quartered themselves or their soldiers upon him. These claims were sometimes compromised by both for an equivalent in tribute; but as a portion, more or less, by way of homage, was generally reserved, and as the reservation, according to its extent, would seem to have had a special denomination, we have an explanation of the perplexing multiplicity of exactions which has so frequently called down the censure of our early writers, who seem to consider *coyne*, *living*, *bonaght*, *sohoran*, *cuddy*, &c. &c., as so many separate taxes, leviable on one and the same holding—an extortion apparently monstrous, and really impracticable, since there are as many denominations of tribute, according to its reserved extent, as, if added together, would amount to perhaps three times the value of the whole land.

So far of the *Finné*, or original members of the kindred, who constituted the great majority of the tribe. But in every tribe there was another class, less numerous and generally less honourable, but in many respects peculiarly interesting and important, particularly as regards the origin of the *feudal law*. The subject of feudal tenures has occupied the attention of the most distinguished English lawyers and historians. The origin of the system has been in all cases referred more or less to the necessities of military conquest, and its genius has been invariably considered as quite distinct from that of any pastoral constitution. The remains of the brehon law however would go far to show that the feudal and pastoral systems, if not to some extent identical, have been in their origin closely and necessarily connected. The system laid down above is so far calculated for the government of a society composed of tribes, each tribe possessing the allodium of its own district, and the mass of its members holding in common. But co-existent with the first practical development of such a system, if not actually contemplated in its very rudiments, arises the necessity of providing for those members of the community who, either by chance, or choice, or compulsion, have been separated from their particular kindreds, and have thus no proper *Finné* with whom to claim a share. Such individuals could not expect to participate in the rights of blood enjoyed by those tribes among whom they might be dispersed, neither could they be received by the commonalty of those tribes as tenants on their fluctuating possessions. To provide for them, it was neces-

sary that a certain portion of the land should be set apart for the reception of strangers. To prevent the confusion of many landlords, the profits of these tenements were allotted to the chief, who could thus afford to exact a lighter tribute from the *Finné* of his tribe. To induce the better sort of strangers to settle among them, the chief was empowered to grant some of these tenements in perpetuity, but the greater portion was usually let at will. As for those who had only their labour to offer in lieu of the chief's protection, they were received on his private demesne lands, and became his serfs. Admission to the upper class depended on the stranger's ability to pay the entrance fine on one or more of the disposable tenements. These tenements consisted of a homestead with a certain scope of ground annexed. The homestead was denominated a *Rath*; to constitute a legitimate rath five things were requisite, namely, a dwelling-house, an ox-stall, a hogsty, a sheep-pen, and a calf-house: these buildings were generally surrounded by a ditch and rampart, and formed if necessary a place of defence as well as of residence. There is one very prevalent error with regard to raths in Ireland; namely, that they were Danish erections, and designed solely for military occupation. The term "Danish rath" is altogether a misnomer. The original titles of raths, according to the classification of the brehon law, were drawn solely from the circumstance of their erection and occupation by the natives themselves; as for example, among many others, the *Finné-rath*, a homestead occupied by the original kindred; a *Mer-rath*, one rented by stranger tenants for the first time; an *Iar-rath*, one occupied by stranger serfs on the chief's demesne lands; a *Saer-rath*, one of which the stranger tenant enjoyed the perpetuity; a *Forgu-rath*, a secondary tenement appurtenant to the *Saer-rath*, &c. &c. The entrance fine of such a tenement was denominated *fal*, and for the legitimate rath amounted to fifty head of cattle. But the most important term in this vocabulary is that applied to the stranger tenant himself. As distinguished from the *finné*, or original clansman, the stranger tenant was called *Fuidhir*, and his tenure *Fuidh*. Now these terms are pronounced respectively *Feuer* and *Feu*, the identical words still employed in Scottish law to indicate the freeholder and his freehold. Hence that they are the radical form of the other feudal derivatives, such as fief, fee, &c., seems more than probable; and when we come to consider more closely the relative situation of the Irish ree-feuer, it will appear that there is something in it very analogous indeed to the older forms of pure feudal tenure. First, the allodium of the soil vested in the representative of the tribe, so that the tenure of the ree-feuer holding of the chief might be considered as *in capite*, with a power in many cases of granting mesne tenures to others. Secondly, at the death of the chief a stated fine was paid to his successor. Thirdly, females could not inherit. Fourthly, raths were liable to escheat; and Fifthly, the tenant was bound to serve the chief in war, and to diet certain numbers of his soldiery at all seasons. Of the more minute characteristics of the perfect feud as introduced by the Normans into England, such as escuage, wardship, ransom, &c. &c., there are so far few discoverable traces, but enough has been shown to give good ground for considering the Irish law of feuers, connected as it necessarily was with the pastoral constitution of their society, as the original form of feudal tenure among all the Celtic nations. Feuers were classified according to the circumstances of their migration; as those who had voluntarily left their former tribe to seek their fortunes; those whose tribe had been dispersed in war, and those who had fled or been expelled their tribe for debt, for robbery, for piracy, or murder. The first three classes only had the privilege of becoming ree-feuers; criminal fugitives were admitted only to a temporary protection, which they paid for by cattle or hand-service, on the private demesne lands of the chief, until he should compound with his prosecutors, after which they usually became his serfs or bondsmen. In the 'Annals of Ireland, translated from the Irish of the Four Masters,' by Messrs. O'Donovan and Connellan, it is stated that the usual mode of descent was by gavel-kind. Bond-feuers were attached to the soil; the lands to which they were assigned being denominated *Betagh* lands, and they themselves being frequently granted with the soil, as appears in many ancient deeds, where they are specified under the name of *Betaghs*.

Thus then it would appear that the country was occupied by kindreds called *Finné*, holding for the most part in common, and by *Feuers*, who were either tenants by rent and service, or vassals of the chief. The tributes of chief to superior chief, up to the supreme king of the whole island, were regulated by established precedents. The collection of these rules for the kingdom of Munster is entitled 'The Book of Rights,' and is still extant.

So far of the common law; next as to the statute law of the Irish. Whether these particular enactments were decreed by a general assembly, as asserted by some, or by local chiefs, as affirmed by others, is a question not at present capable of satisfactory consideration. The books containing them, of whatever age, profess to be but transcripts and collections, with frequent references to similar compilations of still older date; but the text appears to be original, as its dialect is so antiquated as to require the assistance of frequent glosses, themselves very difficult to be deciphered, and even when translated not by any means easily understood. The collections are interspersed with numerous moral sentences, occasionally also with superstitious dogmas: as an instance of the first, "Heaven is like a chariot on wheels, the more you push against it the farther it flies from you;" and as an example of the second, "There are seven witnesses against a wicked king;

namely, division in his councils, strained interpretation of the laws in his court, dearth, barrenness of cattle or lack of milk, a blight of fruit, and a blight of seed sown in the ground: these are as lighted candles to expose the misgovernment of every king."

The number seven would seem to have been held in much the same esteem as the mystic number three. There are, for instance, "seven classes of persons whose anger is not to be resented; namely, bards, commanders, women, prisoners, drunken persons, druids, and kings in their own dominions." There are again "three deaths not to be bemoaned; the death of a fat hog, the death of a thief, and the death of a proud prince: three things again which advance the subject; to be tender to a good wife, to serve a good prince, and to be obedient to a good governor." In this last example the same idea is repeated in order to complete the triad. What virtue can have been supposed to reside in these peculiar forms of expression it is hard to conceive. The only assignable reason for their use seems to be that they were thus more easily committed to memory. The system however does not appear to have been used to any such extent in Ireland as in Wales; triads, in fact, form the bulk of Howell Dhu's laws, and those of the most arbitrary and absurd description.

But to proceed with the more practical and intelligible portion of these collections, the laws defining specific crimes and their punishments. It is said that previous to the reign of Felimí Reachtair, or the Lawgiver, the *lex talionis* prevailed in Ireland, and that he altered that code for a system of retribution by mulct about A.D. 164. Parricide, rape, and murder, under certain circumstances, still remained punishable by death; but whether in consequence of this reform in the old law, or by immemorial custom, all other offences were thenceforth provided against in the brehon law by definite fines. The retribution thus exacted was denominated *eneclan* for *eric*, terms applicable also to rents, prices, and value in general. This system of erics has been justly censured by all English writers on the history of Ireland. But in this, as in most other instances, the censurers of the Irish have exaggerated the evil by considering it as peculiar to that people. So far however from being confined to the Irish, this mode of retribution by eric has been practised at one time or other by almost all the nations of Europe. The Greeks, the Romans, the old Germans, the Franks, the Saxons, the Welsh, all punished our present capital offences by a fine. The only difference lies in the word to express it, *poine* (*poena*), *multa*, *weregild*, *manbote*, *sarhaad*, and *eric* being synonymous terms in their respective languages. In England at the time of the Conquest, every man had his value; in Wales, even to the time of its incorporation with England, not only had every man his own value in gross, but the particular value of all his members severally laid down by law, as six oxen and ten shillings for the two hands, a like sum for the two eyes, half that sum for one of either pair, so much for the ears, lips, nostrils, &c., and these again varied with the rank of the maimed individual. It is not then to be considered either unexampled or monstrous to find an Irish chieftain requesting of the lord deputy to fix his sheriff's eric, that he might know what he should have to pay, in case of that officer coming by his death at the hands of any of his people. The amount of these erics, the different persons liable for their payment and entitled to their receipt, the proportions of these claims and liabilities, the adjustment of value and the living money by which the various proportions of the mulct were paid, these and the further punishment of the offender in each case required a very minute and complicated system of enactments. That the old Irish were acquainted with coined money is asserted by numerous authorities; that they used large quantities of the precious metals as a medium of value is unquestionable; but as none save chiefs and lords of territories were required to pay tribute in metal, the dealings of the mass of the people were calculated for the standard of living money as closely as the nature of the medium would permit. Cattle were accordingly classified; and no doubt it would raise a smile on the countenance of a modern merchant to be told of calves, yearlings, heifers, strippers, in-calf cows, &c. representing the fractional parts of the standard of currency, but such has been the original pecuniary substitute in every country; and when we have the learned Selden declaring that "pounds and shillings were not abundant in England in 1004, but paid in truck and cattle," we can consider the practice in a less intolerant spirit than those who, writing but a few centuries after the use of coined money had become common among their own countrymen, have represented the barbarism of the Irish in this respect as a thing almost unheard of before. It has been seen that in proportion to the number of cattle possessed by each member of the tribe was his share of the common tillage lands. Thus cattle were not only the standard of value, but the qualification for, and a necessary concomitant of, property. The land was thus by a sort of legal fiction an appurtenance of the stock; so that to say of a person under this system that he possessed a hundred cows, implied not only that his herds amounted to so many head of cattle, but that in addition, and as a necessary appurtenance of his estate in them, he also possessed the grazing of a hundred cows, and the share proportioned to a hundred cows in the common tillage lands of his tribe. Every addition to the number of a man's cattle was therefore a virtual accession of land and produce, and *vice versa*; and thus a mulct of cattle fell as heavily on the granary as on the larder or dairy of the fined individual; for these proportionate partitions of the land took place at stated periods, and each man's harvest fluctuated with his

herds as they bore a greater or less ratio to the aggregate of all the cattle of the rest. The division of the ground into portions so uncertain precluded the use of permanent fences on those arable commons which were probably separated from the pasture by only one exterior circumvallation, while each man knew the portion that was to fall to his particular reaping-hook within. The adjustment of these portions must have been a matter of some difficulty; from an account of a partition of this kind given by Sir Henry Piers, who wrote a history of the county of Westmeath in the year 1682, it would appear that the plan usually pursued was this. The land was divided into equal shares, in the proportion, each to the whole, of the herd of the least proprietor to the whole *creaght* or common stock of all their cattle. These shares were drawn for by lot, in order to give to all an equal chance of getting the worse or better land. He then, it is supposed, whose herds were thrice as numerous as those of the least proprietor, drew three such aliquot parts; he possessing ten times as many, ten such, and so on, the shares being taken here and there as they turned up, and every man cropping his own portion as he thought fit. The system is still remembered in some parts of the country, and a mode of expressing the extent of land among the Munster peasantry is still to say "So much as follows so many cows." Hence, in all likelihood, the term *Bally-boe*, that is, cow-land, a term which has perplexed many writers, in consequence of the varying extent represented by it at different times and in different districts. It appears therefore that by levying all mulcts for infringements of the law in living money, the Irish brehons took the most effectual mode of making their punishments tell on the whole condition and standing of the offender in his tribe, for punishments so inflicted showed themselves, more or less, in every circumstance of his life and fortunes, and affected his landed property in all cases for a whole year at least.

In calculating by the measure, it was necessary again to fix a standard of available aliquot parts. The number three was found most convenient, and accordingly the *cumhal*, a general expression of fixed value, was made to consist of three in-calf cows, and by multiples and fractions of this quantity all other proportions of value were usually regulated. Seven *cumhals*, or twenty-one cows, was the usual eric for murder on the highway. This will appear, at first sight, a very inadequate retribution: but as it is not quite clear whether the relatives of the deceased could not severally recover an eric from the murderer, and as it is an accompaniment of the punishment in this offence, that the criminal loses all right in the common tillage lands of his tribe, no matter how numerous his herds may be, after satisfying the judgment of the brehon, his punishment may not perhaps have been so much disproportioned as it would otherwise appear. Still the possession of numerous herds might thus purchase the wealthy man a privilege of violence. To guard against this, the liability increased with the rank of the culprit. Taking the liability of the ordinary clansman at one, that of the wealthy boor (*bo-aireagh*, pronounced *booré*, that is, a person rich in cattle,) would be represented by two; that of the flaith, or petty chief, by three and a half; and so on to the righ or lord of his country, whose liability is raised in the proportion of seven to one. Robbery was punished, in like manner, with this salutary provision, that if the robber could not be discovered, the holder of the stolen goods should pay his eric. The sanctity of marriage was strictly guarded: the injured husband had his first redress at the hands of his father-in-law; failing him, he might levy retribution on his wife's brothers; failing them again, on her foster-children; and finally, if she had no relations, or if none of them were solvent, her tribe at large had to pay the penalty of her crime.

Next to these, the fines for trespass appear to have been attended to with peculiar strictness and care. Hitherto we have spoken of lands held in common, whether for pasturage or tillage, where there could be no fences, and consequently little trespass; but, before we enter on the code of trespass-eric, it will be necessary to recur to those lands which we have denominated the private demesne lands of the tribe in which the *Deirbh-finné* possessed their distinct inheritance. In the present state of the inquiry, it cannot be precisely ascertained how this inheritance was acquired; but such lands are frequently alluded to in the original laws, and distinctly recognised by Sir James Ware, who admits them to have been freeholds. These lands not being subject to yearly repartition, were permanently defined and fenced, and the exclusive possession enjoyed by their holders is evinced by the extreme jealousy of the law decreeing their inviolability. First, we have the legal fence defined; namely, a trench, two feet in width at bottom, three feet in depth, and three feet in width at top, with a ditch raised on one side, of these dimensions and materials, namely, twelve hands of stone-work three feet thick, twelve hands of sod over that, then wooden stakes two feet asunder driven firmly into the sod, laced with wattles, and rising three hands over all. For breaking through a fence so constructed, the legal fine was thus proportioned: for every breach up to the breadth of three stakes, a heifer or young bull; for every breach above three and under five stakes, a bull full grown; for every breach over five and under eight ditto, an in-calf cow; up to twelve ditto, five cows, and so on in progressive increase. That these lands were considerable enough to be extensively wooded, appears also from the penalties against trespass on timber. The classification and comparative valuation of trees in a country which has usually been considered a wilderness of

forests cannot fail to be interesting. Timber was divided into four classes—airigh, athair, foghla, and losa timber; and the fines for trespass on each were thus proportioned: airigh timber, namely, oak, ash, hazel, holly, yew, and fir—for cutting the trunk, five cows; for cutting or maiming the limbs, a heifer; for the branches, a two-year old. Athair timber, namely, alder, willow, hawthorn, quick-beam, birch, and elm—for cutting the trunk, a cow; for the branches, a heifer. Foghla timber, namely, black-thorn, elder, spindle-tree, white hazel, aspen, arbutus—for each a heifer. Losa timber, or fire-wood, namely, fern, furze, briar, heath, ivy, broom, dwarf thorn—the penalty for destroying [these to be at the discretion of the brehon. Full as the classification here is, it scarcely equals in minuteness that law of Ina, a king of the West Saxons in the tenth century, which estimates the value of a tree by the number of swine its branches could give shelter to.

But perhaps a more remarkable law is that of the Irish brehon regulating the property in bees. Honey and wax must have formed a large portion of the wealth of those days, else the various contingent interests in a species of property so hard to fix as that in a swarm of wandering bees had never been calculated and laid down with such scrupulous nicety. In the first place, the bees themselves are protected by severe enactments against injury of whatever kind. Next, they are to be left free, under heavy penalties, to choose their own place of swarming: "to blind the bees" by casting up dust, or taking any other means to force them to descend and swarm on one's own land, while they are flying out of the lands of another, was an offence for which the punishment was no less than expulsion from the tribe and territory. The bees having voluntarily selected and settled on a tree, it then depended on the rank and privileges of the owner as well of the bees as of the tree they had chosen, what was to be the portion of wax and honey reserved for each, and how long the original owner should continue to receive that share, as the bees in all cases ultimately became the property of him upon whose tree they had alighted. The commentators on the old text here complain very bitterly of the clergy, who, it would appear, were particularly fortunate in attracting such wandering swarms to their abbey orchards, where they did not scruple to cover them with sheets, and take other unfair means of securing their stay among them. If the bees, however, were found beyond the sound of a church bell, or the crowing of a cock, in the woods or meadows, the finder was entitled to the whole proceeds, excepting a ninth part, which he had to pay by way of tribute to the chief. If these laws have been rightly translated, the old Irish must have possessed the secret of abstracting the wax and honey without destroying the swarm. In no other collection of laws are the regulations regarding this species of property so copious; in fact, it would require all the space here devoted to this subject to explain the minute and complicated decrees of the brehon law regarding bees alone.

It is equally impracticable to enter fully into the law of water-courses, the enactments on which are very remarkable, inasmuch as the property of the whole water of a stream vests in him out of whose land it first springs, so that the owner of the fountain could levy tribute even on those bridges which crossed the river between banks belonging to other men, as well as on all houses (save those of the chief, the head villager, and the miller,) whose occupants drew water either from the fountain or the stream. Millers were a class peculiarly favoured in these laws: their mill-races were tax-free; their mill-wrights, while pursuing their trade, could not be prosecuted for trespass; and, as above stated, their households were exempt from tribute on all water drawn for their consumption. It is worthy of remark, that by the Jewish law the mill-stone could not be confiscated.

The law of rivers and sea coasts is also laid down at some length; but of the law of roads only one section hitherto has been found. This section, however, is well worth notice, as it contains proof of a much more general design in these laws than we might otherwise be disposed to give them credit for. It provides that the space of the cast of a dart shall be left from high-water mark along the sea-shore for the construction of a public coast-road round the whole kingdom. It is said that some traces of such a road are still to be seen upon the Irish coast. Vallancy states that in his day the country people called it *Brian Boru's road*; and other writers mention the remains of a great inland causeway somewhat similar to the British Watling Street, crossing the country from Dublin to Limerick, which was probably the effect of a similar provision for inland communication.

The law of fosterage is more fully stated. Every member of the *Dathaig-finné*, or gentry of the clan, was bound to send his male children to foster with some family of the *In-finné*, or commonalty; for it was provided that none but fosterers could claim full eric. The *Agairer*, or foster-fee, was a stated sum payable by instalments during the child's minority. While the child was thus under age, the foster-father was bound to pay one-half of his fines, in return for which the young noble or idil-man was ever after bound to protect his new kindred, and in particular to pay all fines incurred by his foster-mother, except in case of adultery, when the liability first fell upon her father and brothers, if alive and solvent.

The law of tuition provides for three chief branches of education, namely: knowledge of cattle, as being the first and most important in a pastoral community; next, knowledge of agriculture; and, finally, of

navigation; instruction in letters being an indispensable branch of each. These attainments were acquired under tutors hired for the purpose, and paid by the father or foster-father, according to the arrangement of the *Agairer*, the foster-father himself being always the youth's instructor in all military and athletic exercises. The tutors alluded to were the *ollamhs* or bards, who also acted as clerks and notaries under the brehon. The offices of these functionaries, as well as of the physician, were hereditary, but not, as is generally supposed, subject to the law of primogeniture; the judge, poet, or doctor, being at liberty to select from all of his own name those apprentices whom he might think most promising in his peculiar profession. The brehon, as a judge, was held personally in great reverence, and was always considered as a neutral in war.

The law of physic proportioned doctors' fees to the rank of the patient, and the nature of the complaint. If a cure was not effected, the doctor had no pay; but where the treatment proved successful the recompense was very liberal, as fourteen *cumhals* or forty-two cows for the cure of a bishop or provincial king, seven and a half *cumhals* for that of a lord of a country, three for that of a *bovaré*, and two for a member of the commonalty.

It is disputed whether the new series of enactments were sumptuary or merely valuatory. Dr. Ledwich adopts the latter opinion, but the tenor of the translated fragments would seem rather to imply the former. They are said to have been enacted by Mugdories, the daughter of Mogha Muadhad, a king who lived in the 2nd century. By them a certain value is established for various articles of dress and luxury; as, for example, a mantle wrought with the needle is valued at a steer or heifer. The dress of a petty chieftain's lady is estimated at three cows; that of a head villager's wife at two; that of a bard and his wife together at three; and that of a bishop at six. The bodkin or brooch of any one under the rank of a *bovaré* was in like manner priced at three heifers; that of a *bovaré* at five; that of a Flaith or petty-chief at ten; and that of a king or lord of a country at thirty. Of the same value in each degree was the bridle. The belt was estimated proportionately at about a third; and in like manner with regard to arms and armour, drinking-cups, &c. &c.

As to forms of trial, there is nothing preserved which so far throws any light upon this portion of the inquiry, except one very interesting fragment, namely, cases of disputed inheritance of lands were to be judged by twelve voices, one dissentient voice invalidating the verdict. This was the ancient law, and the commentator observes that the hardship of its extreme strictness occasioned its practical repeal.

Such, so far as has been hitherto collected from the ill-arranged and defective materials, would appear to have been the old system of rude jurisprudence under which the Irish people lived prior to the invasion of the Anglo-Normans in the 12th century. The conquerors brought their own laws with them; but the progress of the more complicated and formal feudal system of the continent in displacing its primitive originator and rival was necessarily very slow. The brehon law offered many attractions to ambitious individuals desirous of establishing a self-contained despotism in each of their several territories; and while the particular duties and services done by the new feudal law were rigorously exacted, the general privileges of the English constitution were denied. The subjects of the Anglo-Norman conquerors thus participated in the evils of both systems; for the protection of judicial trial by the law of England could not be claimed by the serfs of remote districts; and the power of the conquerors was too arbitrary to permit any operation of the brehon law within their bounds which was not for the sole interest of the lord; thus, the poor native of the pale was mulcted under both laws and protected by neither. It is not surprising, therefore, that the lapse of a Norman noble into mere Irishism, by which he acknowledged the brehon code alone, was anxiously encouraged by his dependents; and such were the inducements of the system itself for turbulent and ambitious spirits, that few of the adventurous nobles who first established themselves in Ireland resisted the temptation. To guard against defection so ruinous to the whole policy of the conquest, many statutes were enacted in the parliaments of both countries. These at first were for the encouragement of the English law only, but afterwards it became necessary to take measures of prevention as well as of discouragement. The first positive act against the practice of the brehon law within the pale was passed by the parliament held at Kilkenny by Lionel Duke of Clarence, in 1362; by which the offence is declared high treason. This was followed by the 18th Henry IV. c. i. ii. iii., and the 28th do., c. i., with similar prohibitions and penalties. The prohibition, however, had little effect. The open defection of the great families of De Burgho, Bermingham, and various branches of the Fitzgeralds, in Ulster, Connaught, and Munster, kept the dangerous example constantly before the eyes of the nobility on the borders of the pale, and each successive rebellion tended to increase the evil: for if the government were successful, the border barons, on whom the maintenance of that advantage afterwards depended, were proportionably more indulged; and, if the Irish prevailed, their yielding under such compulsion was the more excusable. A good example of the anomalous state of society produced by the intermixture of the two systems on the borders of the pale may be adduced from the reports made by various corporate towns of Leinster to the commissioners appointed by

Henry VIII. to inquire into the abuses of the Irish nobility in 1537. The following is an abstract of some of the most remarkable complaints. "All the freeholders, lay and spiritual, charged their tenants *coyne and livery*, with *foy and pay*, with *summer-oats*, with *cuties and cashies*, with *black-men*, with *black-money*, with the maintenance of *mustrons*, and with *carriage* and service in general. Lord Kildare and Lady Catherina Poer not only required coyne and livery for their own horses and boys, but also for those of all their guests, English or Irish, particularly when they kept Easter or Christmas. When either he (Kildare) or Poer, or Ossory, hunted, their dogs were supplied with bread, milk, or butter. When the deputy or any great man came to Lady Poer, she levied a subsidy at her pleasure for meat, drink, and candle, under the name of '*mertyagh*.' When Ossory or Poer married a daughter, the former demanded a sheep from every husbandman, and a cow from every village; and when their sons were sent to England, a tribute was levied on every village or plough-land. Lady Poer took of a tenant who had his horse or cattle stolen, 5 marks for his want of vigilance. Sir Thomas Butler exacted 10 marks at Easter, if his subjects had passed the year without galenglass or spearsmen. William Bermyngham required 16 quarts to the gallon, in payments by liquid measure. Some lords took the tenants' produce at prices fixed by themselves, and thereby were enabled to forestall the markets. The brehon, who was kept by Lady Catherina Poer, took for his judgment, called '*sylogag*,' 16*d.* of every mark sterling, both of the plaintiff and defendant, &c., &c." By these tyrannical practices, resulting from the union of the worst parts of both systems, the brehon law fell into extreme odium, but they are chiefly the exorbitancies and malpractices of the class which have been quoted by English writers who censure it; so that if the views here taken be correct, that odium has been in great measure undeserved. Indeed the nobles of the pale seem to have established a separate code of laws for their own government, known as the *Statutes of Kileash*; and we find them, in the reign of Henry VIII., inflicting a penalty of five marks on the individual who would sue by any other law. If these statutes be the index to such practices as those quoted above, it is little to be wondered at that the brehon law, which bore the blame of all, should have been denounced as it was. Great efforts were accordingly made, both in this reign and in Elizabeth's, to supplant the brehon law; the 3rd and 4th Philip and Mary, c. v. is also directed against some of its effects; but it was not till the 3rd of James that the final extirpation of the old law was effected. The whole kingdom being then divided into counties, with their several sheriffs and circuits of assize, the brehon law became a mere subject of inquiry to the antiquary, and as such, at the present day, possesses perhaps greater interest than any other branch of Irish or Celtic archaeology. We may now hope ere long to see a full and perfect translation, which cannot fail to throw much light on the accounts of the early state of civilisation in Ireland.

BREIDIN. A crystallisable substance, found in the resin of the *Canarium album*.

BREIN. A fusible, crystallisable, neutral body, existing in the resin of the *Canarium album*.

BREVE, in Music, a note double the length of a semibreve, and thus formed, || $\circ$ ||, or || = ||. The *breve* (from *brevis*, short), which in duration takes twice the time of the longest note now in ordinary use, was a short, brief note, three centuries ago, as the term clearly proves. Musicians have proceeded by degrees till the quarter-demisemiquaver is become our *minimum*, being $\frac{1}{256}$ of the *breve*. Indeed some have gone so far as to introduce the half-quarter-demisemiquaver; among whom is Beethoven.

BREVET, in France, denotes any warrant granted by the sovereign to an individual, in order to entitle him to perform the duty to which it refers.

In the British service, the term is applied to a commission conferring on an officer any degree of rank *in the army* above that which he holds in his particular regiment; which, however, does not carry with it the corresponding pay. Brevet rank does not exist in the royal navy, and in the army it neither descends lower than that of captain, nor ascends above that of lieutenant-colonel. It is generally given as the reward of some particular service, though it used to be the custom to give periodical brevets, by which all officers of a certain standing received a step of brevet rank.

Brevet rank does not promote an officer over the heads of those in his own regiment; but when serving on courts-martial formed of officers drawn from different regiments, or when in garrison, or when joined to a detachment composed of different corps, he takes precedence according to the rank given him in his brevet, or according to the date of any former commission; but while serving on courts-martial, or with a detachment composed only of his own regiment, he does duty and takes rank according to the date of his commission in that regiment. Brevet rank, therefore, is to be considered effectual for every military purpose in the army generally, but of no avail in the regiment to which the officer holding it belongs, unless it be wholly or in part united for a temporary purpose with some other corps. (See Samuel's '*Historical Account of the British Army*,' p. 615.)

Something similar to the brevet rank above described must have existed in the French service under the old monarchy; for, according to Père Daniel (tom. ii. pp. 217 and 227), the colonel-general of the

Swiss troops had the power of nominating subaltern officers to the rank of captains by a certificate, which enabled them to hold that rank without the regular commission. The same author states also that if any captain transferred himself from one regiment to another, whatever might be the date of his commission, he was placed at the bottom of the list in the regiment which he entered, without, however, losing his right of seniority when employed in a detachment composed of troops drawn from several different regiments.

The introduction of brevet rank into the British army, as well as that of the half-pay allowance to officers on retiring from regimental duty, probably took place soon after the revolution in 1688. But the practice of granting, when officers from different regiments are united for particular purposes, a nominal rank higher than that which is actually held, appears to have been of older date: for in the '*Soldier's Grammar*,' which was written in the time of James I., it is stated that the lieutenants of colonels are captains by courtesy, and may sit in a court of war (court-martial) as junior captains of the regiments in which they command. (Grose, '*Military Antiquities*,' vol. ii.) It was originally supposed that both officers holding commissions by brevet and those on half-pay were subject to military law; but, in 1748, when the inclusion of half-pay officers within the sphere of its control was objected to as an unnecessary extension of that law, the clause referring to them in the Mutiny Act was omitted, and it has never since been inserted. In 1786 it was decided in Parliament that brevet officers were subject to the Mutiny Act or Articles of War, but that half-pay officers were not. (Lord Woodhouselee, '*Essay on Military Law*,' p. 112.) Brevet command, or rather local rank, a species of brevet rank extending only to a particular country during the continuance of war, was frequently conferred on officers during the Peninsular and Crimean wars.

BREVIARIUM was used among the Roman writers to denote a book introduced by Augustus, containing the accounts of the empire, the enumeration of the military, &c. (Sueton. '*Aug.*' c. 28.) The design of this *breviarium* was to explain to the Roman people the manner in which the monies levied upon them were applied, not to the emperor's private use, but for public purposes. Tiberius laid aside the *breviarium*, but it was resumed by Caligula. (Sueton. '*Calig.*' c. 16.)

BREVIARIUM ALARICIANUM is now the usual name of the code which was compiled at the command of Alaric II., king of the Visigoths, from the Roman law and the Roman jurists. It was completed A. D. 506, in the twenty-second year of his reign. The code was confirmed by the nobles and bishops, and signed by Anianus, the referendarius of Alaric; a circumstance from which the erroneous inference has sometimes been made that he was the compiler of it. The title *Breviarium Alaricianum* was only introduced in the 16th century; it was sometimes called *Lex Romana*, and sometimes *Lex Theodosii*, in respect of the most important part of its contents.

The contents of the *Breviarium* are formed of abbreviations or compilations from the following sources: 1. *Codex Theodosianus*, 16 books; 2. *Novellæ* of Theodosius II., Valentinianus III., Marcian, Majorian, Severus; 3. The *Institutiones* of Gaius; 4. The *Receptæ Sententiæ* of Paulus; 5. *Codex Gregorianus*; 6. *Codex Hermogenianus*; 7. *Papinianus*, lib. 1. *Responsorum*. Accordingly the code was composed of Imperial Constitutions, or *Leges*, as they are properly termed in the *Breviarium*, and of the writings of Roman jurists, which in the *Breviarium* are termed *Jus*.

This Code is of some value for the history of the Roman law, as it contains extracts from portions of the Roman law which are wholly or partially lost, as the work of Paulus, and from the first five books of the *Theodosian Code*, which however, owing to recent discoveries, are less imperfect than they were. The discovery of the *Institutiones* of Gaius [GAIUS, P. C.] has rendered that part of the *Breviarium* in which Gaius was epitomised, of small value. The lacunæ in Gaius cannot be filled up from the *Epitome*, because the compiler paid little attention to retaining the words of the original, but the *Epitome* shows what matters were discussed in those parts of Gaius where the MS. is defective. The whole of the *Breviarium* is contained in the '*Jus Civile Antejustinianum*,' Berlin, 1815. For full information on this subject, the reader is referred to Savigny's celebrated work, '*Geschichte des Römischen Rechts im Mittelalter*,' v. ii. c. 8; or to the French translation by Monsieur Guénoux, v. ii. c. 8.

BREVIARY, or canonical hours, the name of the daily service-book of the Church of Rome, consisting of the offices of matins, prime, third, sixth, nones, vespers, and the complines; that is, of seven hours, according with the saying of David, Ps. cxix. 164: "Seven times a day do I praise thee."

The origin of the name is variously accounted for: some deriving it from the little books of psalms and lessons read in the choir, collected out of large volumes, which the old monks carried with them in their journeys; others from the shortened service which was used in the papal palace of the Lateran, afterwards brought into general use. Grancolas, in his '*Commentarius Historicus in Romanum Breviarium*,' 4to, Ven., 1734, says, "*Breviarium dictum est quasi Breve Orarium, sive Precum Epitome*;" an explanation countenanced by the circumstance that the name of *breviary* is not older than the year 1080, adopted after the offices which it contains had been revised and contracted.

In earlier times the designations of this service-book had been 'Horæ Canonice,' 'Opus Dei,' 'Divinum Officium,' 'Collecta,' 'Agenda,' 'Cursus,' &c. (Grancolas, *ut supr.*)

The Breviary originally contained only the Lord's Prayer and Psalms, to which were subsequently added lessons from the Scriptures. Various additions were afterwards made by the popes Damasus, Leo, Gelasius, Gregory the Great, Adrian I., Gregory III., and Gregory VII.; and in the progress of time, in compliance with the superstition of the day, the legendary lives of the saints were inserted, full of ill-attested and improbable facts. This gave occasion to many revisions and reformations of the Roman Breviary, particularly in the councils of Trent and Cologne, by popes Gregory IX., Nicholas III., Clement VII., Paul III., and Paul IV.; as likewise by some cardinals, and especially by Cardinal Quignon, who carried the reformation of it the farthest.

An additional reason for reforming the Breviary was found in the circumstance that different churches and orders of religious had their several offices, varying from each other, but still under the same name. Grancolas has separate chapters, *de Ecclesiis Orientalium Breviario*—*Distributio Officii apud Græcos*—*de veterum Occidentis Ecclesiis*, præcipue vero *Mediolanensis Breviario*—*de Breviario Ecclesiis Hispaniæ*—*Vetus Ecclesiæ Anglicanæ et Germanicæ Breviarium*—*de veteri Galliæ Ecclesiis* Breviario, præcipue vero *Parisiensis*—*de Breviario Monastico*, &c.

In England we have Breviaries more particularly appropriated to the cathedrals of York and Salisbury: an edition of the former, printed at York in 1526, is mentioned in Gough's 'British Topography'; editions of the latter, printed at Paris, occur in 1510 and 1536. The Breviary "in usum Sarum," was the service-book principally followed formerly in the English churches. But the variety of form, as already shown, was not confined to England; there was scarcely a church in the communion of Rome, in France, Flanders, Spain, Germany, &c., which had not something particular, however inconsiderable, in the form and manner of its Breviary.

Pope Pius V., who adopted the Breviary as decreed by the council of Trent, ordered all former Breviaries to be laid aside, by his rescript dated at Rome 7 id. July, 1568, whether made by bishops, orders of monks, or monasteries. Clement VIII., in another rescript dated 10th May, 1602, recognised Pius V.'s abolition of the Breviaries as used in different churches according to their particular forms of service, and confirmed the Breviary as fixed in 1568. Urban VIII. again confirmed it under a new revision 25th January, 1631. This last revision, by which the work was brought nearer to the simplicity of the primitive offices, is at present the Breviary of the Romish Church in general use. It was published in 1697, under the direction of Ferdinand de Bergem, bishop of Antwerp, entitled 'Breviarium Romanum, ex decreto Sacrosancti Concilii Tridentini restitutum, Pii V. Pont. Max. jussu editum et Clementis VIII. primùm, nunc denuo Urbani PP. VIII. auctoritate recognitum,' fol. Antw. 1697.

The obligation of reading the Breviary every day, which at first was universal, was by degrees limited to the beneficed clergy alone, who are bound to do it on pain of being guilty of mortal sin, and of refunding their revenues in proportion to their delinquencies in discharging this duty. Some of the monastic orders have, with the consent of the pope, their peculiar Breviaries, but they contain no essential variations.

In addition to Grancolas's work already quoted, and the rescripts prefixed to the Breviarium of 1697, the reader may consult Koecherid's 'Bibliotheca Theologiæ Symbolicæ et Catechetica, itemque Liturgica,' 8vo, Guelpherb., 1751, pp. 747-768, where he will find a critical account of the editions of the Breviarium since 1549.

BREWING consists in the process of extracting a saccharine solution from grain, and in converting that solution into a fermented beverage called beer or ale. This art, although a perfectly chemical one in nearly all its stages, has not until very lately been indebted to chemistry for any of the improvements which have been made in its details; this we may attribute to the rare occurrence of a practical chemist being engaged in the operation of brewing. The great brewers, however, have lately made improvements in this matter.

This art is of great antiquity; for we find that the Germans, in the time of Tacitus, manufactured an intoxicating beverage from wheat and barley; and Herodotus (ii. 77), five centuries earlier, says that the Egyptians made a drink of barley. The Saxons also had various drinks of the same class; some made from grain, as *mum*; others from honey, as *metheglin*; but in Germany, in particular, they were early famed for their beer and ale. The towns of Lübeck and Rostock stood foremost in the list for their double beer or Brunswick *mum*, as it was called, at which places it was manufactured to an enormous extent: the latter town exporting, about the end of the 16th century, as much as 800,000 barrels. Heavy duties were, however, levied in this country on these imports, amounting at last, in the beginning of the reign of Queen Anne, to the enormous sum of 15s. per barrel. This heavy impost, together with the improvement in the breweries of this country, soon put a stop to the introduction of this article. Within the last half-century the manufacture of beer and ale has increased to an amazing extent both in England and in Ireland.

The process usually followed by the brewer of the present day may be divided into eight distinct parts, independent of the malting: namely, first, the *grinding* of the malt; secondly, the operation of

mashing; thirdly, the *boiling*; fourthly, the *cooling*; fifthly, the *fermentation*; sixthly, the *cleansing*; seventhly, the *racking* or *vatting*; and eighthly, the *fining* or *clearing*. In considering these various subjects, it will be better first to go over the processes in their order, and then return to the particulars of the principal processes, as respects the heat and precautionary details, &c. In brewing the various beers, as ale, porter, and table-beer, three distinct kinds of malt are employed; the pale and amber malts, the brown or blown malt, and the roasted or black malt. The first of these alone is used for ales; and for the finer qualities or higher priced, the malt is dried very pale indeed. This first quality of grain gives the saccharine extract; the second, or blown malt, gives the flavour to porters and stouts; and the last variety is used only as a colouring matter. The roasted malt is also sometimes called patent malt. [MALT.]

The grain being selected, it is ground either by millstones, or by allowing the malt to pass between two cylindrical iron rollers, placed horizontally at a certain distance from each other, with the space between them regulated by adjusting screws according to the size of the grist required. Many brewers prefer a fine grist (as the crushed malt is called); while others, on the contrary, consider that a greater extract can be obtained from a coarse one. Some use the millstones in preference to the rollers; others like the rollers best; others again employ both. In the last-named case, the brewer uses a circular sieve called a separator, through which the grist passes from the millstones; and only the grains that may have escaped this operation are carried to the rollers to be crushed.

The grist being thus prepared is now ready for the process of mashing. The mash-tun is usually of wood, varying in size according to the quantity of malt to be wetted, and having two or more holes called taps in the bottom. From one to two inches above this bottom is a false bottom pierced full of small holes, on which the ground malt is placed; the hot water is then admitted, and the grist is intimately mixed with the water. For this purpose it is either worked by machinery consisting of a horizontal axle supplied with vertical arms around its circumference, and these again having comb-like projections, the whole of which is made to traverse round the tun; or the *goods* (as the malt is now technically called) is worked up by means of instruments termed mashing oars, so as to cause the whole to assume a perfectly homogeneous consistence. This being completed, the whole is allowed to stand at rest for a certain time; the taps are then opened at the bottom of the mash tun, and the infusion or sweet wort is allowed to run off into a vessel called the underback, from whence it is pumped or otherwise conveyed to the copper for boiling. When the taps are spent they are closed, and a fresh quantity of hot water is run on for a second mash. Brewing coppers for small breweries are generally open; but in the large establishments dome coppers are employed, and on the dome of the copper a vessel is constructed called a pan, by which both time and fuel are materially economised; cold wort or water is placed in this vessel at the same time that the boiling is going on in the closed copper below, the steam from which is also driven into the pan, so that in the course of the time required for the wort to boil, the fluid in the pan is raised to the boiling temperature also. When the whole of the worts are pumped into the copper the hops are thrown in, and the boiling then commences. Large coppers are supplied with an apparatus called a rouser, consisting of a vertical rod of iron extending to the bottom of the copper, with chains pending from the horizontal arms which branch off from it, and which are dragged round the bottom by machinery so as to prevent the hops from settling down and burning. When the boiling is complete, the whole contents of the copper are turned into the hop back or jack back, which is a large vessel, having a false bottom for large brewings, and a sieve partition at the corners for small ones.

As the boiled worts drain from the hops, they are allowed to run into or are pumped into the coolers. These hops, when sufficiently drained, may be again boiled with a second copper of wort, or with the return wort or table-beer. The coolers are large shallow vessels, placed in as open a part of the brewery as possible, so as to command a free current of air over the whole of their surface: they may be constructed of either wood or iron. The latter possesses many advantages from its cleanliness, and the exposure of a large radiating surface to assist the cooling. Fans and blowers are sometimes used to assist the rapidity of this part of the process. The fans are placed in the middle of the cooler and whirl round, producing a considerable movement and current. The blower consists of a light iron paddle-wheel working within a box closed at all parts, except round the axle of the wheel, at which the cold air enters, and at the opening of the wooden pipe through which it is expelled. When sufficiently cool, the worts are allowed to run into the fermenting tun. As great injury may arise from the worts remaining too long in the coolers, more particularly in summer, it becomes necessary to employ artificial means of cooling by refrigerators, the principle of which is this: a current of cold water flows through a main in one direction, while the hot wort is made to traverse in the opposite, either in an inclosed pipe within the liquor main, or around the exterior of the cooling surface; the water becomes warm by cooling the wort.

The next operation, that of fermentation, is carried on in a vessel called a gyle, or fermenting tun, which is either of a square or round shape: the latter is preferable on account of the superior cleanliness.

As soon as the worts begin to run from the coolers, and when a sufficient quantity is in the tun, the yeast is added, being first rendered thin by some of the wort, so as to be easily miscible when thrown into the remainder. When the fermentation has arrived at a certain point of attenuation, that is, when a certain quantity of the saccharine matter of the wort has been converted into alcohol or spirit, it is to be cleansed from the yeast; and for this purpose it is either run into smaller vessels, such as casks or rounds, or the yeasty head is skimmed off from the top; and this is repeated at intervals until the beer is clean. This operation of skimming is generally confined to the cleansing of ales. The rounds or casks are simply filled with the fermenting beer, and so arranged as to be always kept quite full, with a trough or stillion to catch the yeast as it works out at the orifice of these vessels. Great care is taken to keep these casks clean. The beer, being thus cleansed from all the yeast, is now to be either racked directly into casks for ale, or run into vats prepared for it. In extensive breweries a large vessel termed a tank is first used, into which the beer intended to be vatted is allowed to run so as to be perfectly well mixed, and also to deposit a further portion of yeast by standing. The beer is by this means also rendered flat, which is necessary for stock or store beer that is to be kept some time before coming into use.

The last operation the beer has to undergo is the fining or clearing, which is sometimes done by the brewer, sometimes by the publican. The fining material consists of isinglass of various qualities, digested and dissolved in acid beer or sours. Its operation is supposed to be this: the gelatine or soluble matter of isinglass is more soluble in cold acid beer than in sound beer, water, or any fluid containing spirit; and therefore when the finings are added to a well-fermented beer, the gelatine is separated from the medium which held it in solution, and by its separation it agglutinates or collects together all the lighter floating matters which render the beer thick, and ultimately falls to the bottom of the vessel with them, leaving the beer clear and transparent.

The main thing to be observed in all the operations described is cleanliness, without which it is impossible that sound beer can be brewed, let the skill of the brewer be ever so great. The grist should be coarse cut, or, if crushed by rollers, should have the cuticle broken without destroying or breaking in pieces the grain; when this is done, the taps will spend more freely, and a fine bright wort will be obtained. For blown malt, very fine grinding is desirable; and the roasted malt may be ground as fine as possible, so that it will pass the stones or rollers without caking. The temperatures of the mashing liquors for ale or pale grists range from 170° F. to 185°; while for porter, where mixed grists are employed, the mashing heat ranges from 156° to 165°. The length of time for the worts to boil should be about an hour and a half, or until the worts break bright from the hops when a sample is taken from the copper. The proportion of hops to be used must depend so entirely on the beer in process of brewing, and the number of the boiled worts, that no certain rate can be laid down; but 4 lbs. of new hops per quarter of malt should be ample for present-use beers; for keeping-beers for exportation as much as 28 lbs. per quarter have been used, but this is the extreme limit. In fermentation, hardly any two brewers follow exactly the same routine, some using very low heats, others very high; some cleansing early, others late; some skimming off the head, others continually beating it in: these, with a variety of other operations adopted at various stages of the process, give rise to the great variety of different flavoured beers which we have in this country. The temperatures for fermentation range between 56° and 62°; not higher than 60° for ale worts, or above 62° for porter. The stages of a healthy fermentation are, first, a creamy scum rising on the surface: this, after a time, begins to curl and become frosted in appearance; it then becomes rocky, and the air vesicles which appeared frosted enlarge; it then passes to the size of small bladders, and after a short time the head begins to fall: it however rises again, becomes yeasty, the bladders enlarge in size, the yeastiness increases, and, when ready for cleansing, it has a vigorous, rich, yeasty brown and bladdery head. The yeast, after a time, will wear out and cease to ferment the worts healthily; under these circumstances a change must be procured, and at times one or two, before the desired effect will be produced. The yeast used in setting the fermentation should be about 2 lbs. per barrel; but this will vary with the strength of the beer, the extent of attenuation required, and the quantity of worts that are to be fermented together. Good malt and hops are of course indispensable in all these operations, and good materials are at all times more economical than inferior articles bought a few shillings cheaper; a greater extract is obtained, and a far superior article manufactured. Many persons imagine that the peculiarity of the water in different districts produces the recognised difference in the flavour of the beer brewed; but this is erroneous. Good beer may be brewed from hard or from soft water, whether obtained from a well or a river.

Such is a simple outline of the processes for brewing beer and ale. The reader will have no difficulty in conceiving that the mechanism and details of the processes must vary greatly, although the chemical principles may remain the same. In Bavaria the brewing of beer is one of the chief departments of manufacture; they have black beer, white beer, brown beer, thin beer, strong beer, double beer, bitter beer, &c.,—differences which, in England, are expressed by various designations of ale, beer, porter, and stout. Bavarian beer and Scotch ale,

in a general way, differ from English beers and ales in being fermented at lower temperatures. Ale, in England, is brewed from paler malt than beer; porter is brewed from pale malt, coloured with burnt malt; stout is only a superior kind of porter; table-beer is simply poor or weak beer. Malt is the proper material for yielding beer; but imitative beers are brewed from bran, potatoes, spruce, sugar, and treacle. A few flavouring and sweetening ingredients are required and allowable in brewing; but much of the beer retailed in the public houses of London and other large towns is scandalously adulterated,—by the retailers rather than by the brewers, so far as is known. It has been ascertained, by chemical examination, that quassia, gentian, wormwood, broom-top are added to impart bitterness; capsicum, ginger, coriander, orange peel, carraway, to give pungency; opium, cocculus indicus, nux vomica, tobacco, poppy, henbane, to intoxicate; molasses, sugar, treacle, as substitutes for malt; sulphuric acid, alum, vitriol, salt, to impart various properties: some items in this numerous list are generally to be found. The Excise authorities have battled hard against these fraudulent dealings; but the subject is a difficult one to manage.

Much controversy arose in the metropolitan newspapers, a few years ago, concerning the price of London beer, which is as high when malt is cheap as when dear. The price has become, as it were, stereotyped. So attached are the inhabitants of the metropolis to this beverage, and so gigantic are the resources of the great porter breweries, that neither will the former abstain from porter because it is dear, nor will the latter lower the price. Any attempt to compete with the established houses in brewing porter (ale-brewing is subject to more competition) has hitherto failed; there are not more porter-breweries in the metropolis in 1859 than there were in 1839. This probably is due to the fact that most of the public-houses are more or less in the power of the brewers; while, on the other hand, new public-houses or beer-shops, unlike shops in other branches of trade, cannot be opened without magisterial sanction and licence. All these circumstances tend to restrict competition; and thus a gallon of porter costs one shilling when malt and hops are cheap as well as when double the price.

New inventions are occasionally patented in brewing, as in other departments of manufacture. Mr. Tizard, a brewer of Birmingham, has suggested a remarkable arrangement for fermenting the beer. He proposes the use of a subterranean fermenting room, to such a depth as to have a uniform temperature of 45° to 52° at all hours and seasons. This, in our country, would be at a depth of about 70 to 80 feet. The fermenting vessels are to be surrounded with cold water in this subterranean chamber. The cooled wort is to be conveyed by a pipe down into the vessel, and after the processes of fermenting, cleansing, and fining, it is to be drawn up again through racking taps, which only just dip below the surface of the liquid, so as not to disturb the lees of the liquor. This suggestion has, we believe, not been acted on. The same inventor, who is also the author of a Treatise on Brewing, patented in 1857 an apparatus for fermenting and cleansing beer: its principle is that of having a double cover, which rises and falls, and which holds within it either hot or cold water.

A cooler for brewing, introduced by Mr. Davidson, acts in the following way: the wort is pumped up at a slow and regulated speed into a recipient at the top of the machine; it there divides into a series of thin films or streams, and trickles down the inside of a number of thin metallic tubes, set vertically. An upward current of air passes through these tubes, meeting and cooling the hot wort.

The London porter breweries, adverted to in an earlier paragraph, are among the largest manufacturing establishments in this kingdom. The following refers to the statistics of Barclay and Perkins's brewery a few years ago; and as the quantity brewed by that firm annually is certainly not decreasing, the figures may supply a clue to the present scale of operations: About 100,000 gallons of water are required daily; two large steam-engines, of 45 and 30 horse-power, work the machines; there are 24 malt-bins, each as large as an ordinary three-storied house; more than 2000 quarters of malt are used per week; the great brewing-room is nearly as large as Westminster Hall; there are 10 brewing-coppers, each holding 12,000 gallons; the cooling-floor presents a surface of 10,000 square feet; there are 4 fermenting vessels, each of which will hold 1500 barrels of beer; the working-off of the yeast from the beer is effected in 300 vessels, containing 300 gallons each; there is a tank, for the reception of the beer at a certain stage in its progress, 120 feet long by 20 wide; the beer is stored in 150 large vats, of an average capacity of 30,000 gallons each; the largest vat contains 3000 barrels of 36 gallons, or 108,000 gallons in all, and weighs when full not less than 500 tons; the butts, puncheons, barrels, and other casks, in which the beer and ale are sent out to the retailers, are 60,000 in number; and lastly, 200 horses are employed to draw the drays in which the barrels are conveyed through the London streets.

Considered as a source of revenue, beer and ale have undergone some such changes as other articles of commerce. Beer was first made an exciseable article by the parliament in the 19th of Charles I., 1643. In December, 1660, persons by whom it was brewed for sale were required to pay an excise of 2s. 6d. per barrel on strong beer, and 6d. per barrel on small beer. In the following year the same duties were respectively imposed upon strong and small beer in Ireland; but beer brewed in Scotland was not chargeable with any duty until 1695, when the brewers paid 3s. 3d. per barrel on strong beer, 9d. per barrel

on small beer (to which rates the duties in England had been advanced in 1692), and 2s. per barrel on "twopenny ale." In 1697 the rates were increased in England and Scotland to 4s. 9d. on strong beer and 1s. 3d. on small beer. A further advance in 1710 carried the rates to 5s. and 1s. 4d. In 1761 the duties were fixed at 8s. per barrel on strong, 3s. on table beer, 1s. 4d. on small beer, and 3s. 4d. on twopenny ale. In 1802 the distinctions of small beer in England and Scotland, and of twopenny ale in the latter country, were no longer made, and the rates of duty were fixed at 10s. per barrel on strong, and 2s. per barrel on table beer, at which they were continued until October 1830, when the duty on all kinds of beer was wholly repealed. In July 1823, the legislature had sanctioned the sale of a quality of beer between the two kinds last mentioned, to which the appropriate name of "intermediate" beer was given, and upon this kind a duty of 5s. per barrel was payable, until 1830. The above-named rates were in addition to the duties charged in each division of the kingdom upon the materials of which beer is made. [HOPS; MALT.]

An attempt was made in 1806 to impose duty upon beer made in private houses; but this measure met with so much opposition, that it was abandoned by the chancellor of the exchequer, and the impost was confined, as it always had been, to beer brewed for sale by public brewers.

The quantities of "strong," "table," and "small" beer charged with duty in England, Scotland, Ireland, and Wales, between the years 1786 and 1830, never deviated far from 8,000,000 gallons per annum, yielding a revenue varying from 1,900,000l. to 3,500,000l., according to the rates of duty charged. The duty on malt and hops is still retained, but the beer duty has been repealed. Very little foreign beer or ale is imported. British malt liquor is exported, but in a small ratio compared with the home consumption. In the three years ending with 1858, the average annual quantities were thus presented:—

To Australia	176,000 barrels
To the East Indies	133,000 "
To all other countries	151,000 "
	460,000 "

BREZILIN. [BRAZIL WOOD, COLOURING MATTER OF.]

BRIBERY. [ELECTION.]

BRICKS. The small building materials obtained by moulding and drying, either with or without direct contact with fire, a plastic earth for the purpose of supplying the place of stones are called BRICKS, and their use seems to have been coeval with the earliest dawn of civilisation. We read, in fact, in Genesis xi. 3, and in the description of the building of the tower of Babel that bricks "burnt with fire" were even then known; and from Sir G. Wilkinson's work upon the 'Manners, &c. of the Egyptians,' 1st series, ii. pp. 96-99, it is evident that the art of preparing both the sun-dried and the kiln-burnt bricks was familiar to that nation. There are indeed still in existence both public and private buildings in Egypt erected with this material; and the recent discoveries of the ruins of Nimroud show that the Assyrians also were acquainted with its use. Herodotus mentions that in the construction of the walls of Babylon, bricks burnt in a furnace were employed; Xenophon also alludes to them; and Pausanias states that the walls of Mantinea were built of sun-dried bricks, if at least we may judge by the statement that when Agis was besieging the town, he destroyed the walls by turning the course of the river, so that it should wash away the walls of "crude bricks." The Romans, however, of the nations of antiquity seem to have used this class of materials the most habitually; and there are numerous and explicit allusions to the processes adopted in the manufacture in Columella, Varro, Palladius, Vitruvius, Pliny, &c. Wherever there was found to be any difficulty in procuring easily worked building stone, the Romans, in fact, resorted to the use of brick; and they even seem to have given it a species of general preference, for the majority of their great engineering works were executed with bricks, even when it was possible to obtain stone without any great additional outlay. The Roman bricks, however, were more like tiles, in the modern acceptation of the word, than those made at the present day; and, as we shall have occasion to observe, their use rendered necessary the adoption of a style of construction rather different from that of ordinary modern brickwork.

During the early part of the middle ages bricks were little used, and it would even appear that it was not until about the 11th and 12th centuries, that their manufacture was revived in Northern Italy, and in the Rhenish and Flemish provinces. From thence the use of bricks seems to have spread rapidly, until about the 16th century, when it almost universally superseded the use of stone, in countries even wherein the latter material was easily and economically obtained; perhaps in consequence of the absurd fiscal regulations of the times. Of late years the fashion has changed, and bricks are only used when there are local conditions of so imperative a nature as to render it inexpedient to employ the more costly, but more beautiful material. In every country, however, where fuel is cheap, and large deposits of plastic clay are to be found, bricks are almost exclusively employed, on account of their economy, and of the ease with which they are laid. The nature of the fuel, and still more the nature of the clay used, so materially affects the dimensions, and the details of the manufacture of bricks, that it will be impossible to notice all their varieties; it is

therefore proposed simply to describe the more general known descriptions made for the London market, under the various heads of walling bricks, paving bricks or clinkers, and fire bricks.

Ordinary walling bricks may, for convenience sake, be considered first, under the classification of "kiln-burnt" bricks, or "clamp-burnt" bricks, according to the method of their burning; or they may be considered under that of *malms* or *common* bricks, according to the nature of the clay which enters into their composition. The various-coloured bricks, red, white, blue, and black, are obtained from clays of peculiar descriptions, to which attention will incidentally be called in the sequel.

Kiln-burnt bricks are, as their name implies, those which are burnt in kilns; a method usually adopted when fuel is expensive, and the clay is sufficiently stiff and strong to require to be treated like pottery clay. The clays, in fact, which contain a large proportion of carbonate of lime are liable to fuse in the furnace, if exposed to great heat; and, therefore, the bricks made from them require to be burnt in kilns, wherein the heat may be regulated at will. The operation of kiln-burning is slower also than that of clamp-burning, and for this reason especially it is not resorted to in the neighbourhood of London, where the demand is so enormous. The bricks which are burnt in kilns are usually of a better and more uniform colour, and of a more regular form than those burnt in clamps; but they are not usually so well vitrified, nor are their powers of resisting atmospheric influences by any means equal to those of bricks burnt at higher temperatures. Moulded bricks, tiles, and drain-pipes, and in fact, all earthenware, of which it may be desired to retain the particular form impressed by the moulder, are invariably burnt in kilns.

The kilns may be either closed or open, though there can be no doubt as to the superiority of the former system. The closed kilns are made to receive about 24,000, or even 30,000 bricks at a time; but the dimensions usually adopted are to make the chamber for stacking the bricks 10 feet wide, 20 feet long, and about 13 feet 6 inches in clear of the arch. The open kilns receive from 40,000 to 50,000 bricks at the same time; and occasionally in Holland, they are even made large enough to receive three millions at once. In the latter case, however, the advantages of kiln-burning are entirely lost, so far at least as the influence of the burning upon the quality of the goods is concerned.

Clamp-burnt bricks are usually composed of a clay which is fusible with so much difficulty as to require that the fuel should even be mixed in the body of the brick itself; and it thus happens that, from the intimate manner in which the heat penetrates the whole mass, the bricks burnt in clamps are more thoroughly burnt, and consequently are of a more durable nature, than those prepared in kilns. The clamps, however (which are, in fact, only stacks of dried bricks with occasional layers of fuel interspersed), are exposed to great irregularities in the manner in which the combustion takes place; and the quality of the bricks varies sensibly according to the manner in which the combustion has so taken place. Where the fire has been too powerful the bricks run into a species of semi-vitrified state, and are known as clinkers; where the fire has not been powerful enough, the bricks are soft and incoherent, and in this state they are known amongst the London workmen under the names of *grizzles*, or of *place* bricks. The latter phrase, it must be observed, is applied also to the soft kiln-burnt bricks. Clamps are usually made to consist of 500,000 bricks; but very often as many as a million are burnt in one stack; the loss by fracture, clinkering, and underburning is hardly ever less than 10 per cent.

Malm bricks are those which present a warm buff colour, and a close uniform grain, when pains have been taken in their manufacture. They are usually made from the fine clays of the post tertiary periods, in which there is a considerable quantity of the carbonate of lime diffused through the mass in a highly comminuted state, or even occasionally in chemical combination. Where this diffusion does not exist naturally, it is imitated by adding chalk in the necessary proportions; and thence arises the subclassification of the *natural* and *artificial* malms. Great care is required in burning all the descriptions of malm bricks to exclude the ordinary atmosphere from them during the operation of burning; and on this account as well as on that of the chemical nature of the clay, malms are always burnt in kilns. It is also extremely important that no large masses of the carbonate of lime should exist in the bricks; for during the process of burning, the lime would naturally pass into the caustic state; and as this caustic lime eventually would absorb moisture from the air, it would expand, and disintegrate the body of the bricks. It has even happened that walls built of bricks made from clay containing a large proportion of carbonate of lime have swelled bodily, when erected in such positions as to be able to absorb moisture. The best malm bricks are made near Ware, in Hertfordshire; Erith, in Kent: the Suffolk bricks are also, in fact, a species of malms, but they usually are white, from the fact of their possessing an excess of the carbonate of lime in the composition of their clay. Indeed as the calcareous marls, from which malms are made, vary in their composition so much, that the carbonate of lime may be either 14 or 46 per cent. of the whole mass, the colour of the bricks may vary in as distinctly marked a manner. The quantity of oxide of iron present in calcareous marls also varies within a very wide range; or between 2 and 6½ per cent.

Common bricks are made from the coarser descriptions of clays, and the latter are generally so stiff as to require to be mixed with certain proportions of sand, or of coal ashes, to ensure their plasticity. The clay is dug, and exposed to the weather in small pieces, called, near London, *curfs*, in order, as the workmen say, "to mellow," and it is then mixed with the sand or ashes in such a manner as to ensure the equal distribution of those ingredients. This operation is called *soiling*, and it is succeeded by the *tempering*, which is effected by turning over the clay by hand, and subsequently by passing it through the pug-mill, previously to its being carried to the moulder's stool. It is true that most of these operations are required to be performed in the preparation of all kinds of bricks; but the preparation and previous manipulation of common clays require to be effected with more care than is necessary with the clays of a superior quality.

The common bricks are invariably burnt in clamps in England and in Belgium. In England the products are classed, according to their quality, either as *cutters*, or the fine grained rather soft bricks used for cutting ornamental work; *picked stocks*, of a bright uniform colour; *paviours*, or the hardest and most regular bricks, fitted for the purpose indicated by their name; *common stocks*, *grizzles*, *burrs* or *clinkers*. Many of these names are applied to the differently coloured bricks before referred to, and it may suffice here to say that the red, blue, or black colours in question result from the variable proportions of the hydrous oxide of iron in the clays, and they change as the clays themselves may be affected by the degree of heat to which the bricks are exposed.

Paving bricks are made from clays containing silica, in a form which would allow of its passing into a state of semi-fusion, and thus of producing a hard imperishable material. The best paving bricks are made from the mud of the Yssel in the Netherlands, and they are known in commerce under the name of Dutch clinkers; very good materials of this description are, however, made at Uppingham from the clays of the lower oolite; or in the neighbourhood of Birmingham, from the clays of the carboniferous series.

Fire bricks are those which are used in positions where they are required to resist the direct action of fire, and they must, therefore, be of an infusible nature. This term is, however, only to be used relatively; that is to say, it must be understood that the danger of fusibility will vary in every different description of furnace, and the bricks required to resist the heat of an engine furnace will be exposed to a heat which will be far less than that of a porcelain kiln. Whatever be the degree of heat to be resisted, the general characteristics of the clay fitted for fire-bricks are that it should be as free as possible from any mixture of lime, magnesia, or iron; and that the silica should be present in the soluble form. The best fire-bricks are made at Stourbridge, but articles of nearly equal value are made at Edinburgh, Newcastle, Glasgow, South Wales, and latterly the peculiar beds of the subereticous formations near Farnham, in Surrey, have been worked for the purpose of making fire goods of a very peculiar nature. Great pains are required to be taken in preparing the clay for fire-bricks, in order to avoid any unequal contractions or expansions; and it is essential that the bricks should be exposed, whilst in the kilns, to a greater degree of heat than they are likely to be called upon to resist subsequently. Fire-bricks are all moulded by hand, and kiln-burnt.

Dr. Richardson gives the following analyses of some of the fire-clays of Newcastle, which may be referred to as illustrating some of the extreme varieties of this class of materials.

Numbers	1.	2.	3.	4.	5.	6.	7.
Silica	51.10	47.55	48.55	51.11	71.28	83.29	69.25
Alumina	31.35	29.50	30.25	30.40	17.75	8.10	17.90
Oxide of iron	4.63	9.13	4.06	4.91	2.43	1.88	2.97
Lime	1.46	1.34	1.66	1.76			
Magnesia	1.54	0.71	1.91	trace	2.30	2.99	1.30
Water and organic matter	10.47	12.01	10.67	12.29	6.94	3.64	7.58

The dimensions of bricks vary, as was said before, not only on account of the quality of the clay from which they are made, but also in many cases on account of the fiscal or excise laws of the locality. Upon the Continent bricks are usually made about $8\frac{3}{4}$ inches in length, by $4\frac{1}{2}$ inches wide, and $2\frac{1}{8}$ inches thick; but in consequence of the old excise laws of our own country the dimensions of English bricks are almost invariably 9 inches in length, by $4\frac{1}{2}$ inches wide, and $2\frac{7}{16}$ inches thick. The ancient Romans, and even the modern Italians, have adopted very different dimensions from either of the above; for in their buildings bricks are occasionally to be found having a length of 30 inches, by a width of 9 inches, and a thickness of $2\frac{3}{4}$ inches; and in the old Roman wall of London itself the bricks were $17\frac{1}{2} \times 11\frac{3}{4} \times 1\frac{1}{4}$. The Austrian bricks are often $12 \times 6 \times 2\frac{1}{2}$; the old *Reuzen* bricks of Friesland were made $13 \times 6\frac{1}{2} \times 3\frac{1}{4}$; whilst the ordinary Dutch *waal steen* are $7\frac{3}{4} \times 3\frac{3}{4} \times 1\frac{3}{4}$. In fact, every imaginable proportion and dimensions have been adopted; but the principles which ought to regulate them are, firstly, that they should not be such as to interfere with the proper degree of burning; and, secondly, that they should be such as that a working man could easily handle the bricks without undue fatigue; consistently with these conditions, the larger the bricks are,

the better and more economical will they be, both in manufacture and in use.

In laying bricks, the most important precautions to be observed are, that the cementitious material should be equally and carefully applied, and that the joints of the bricks should never be immediately over one another; or, to use the workmen's phrase, the bricks "must break bond." There are two descriptions of bond commonly adopted in England, which are known under the respective names of the *Flemish* and the *English bond*, about the relative merits of which there is a great diversity of opinion. The Flemish bond is made by laying the bricks in a course, alternately lengthwise or across the line of the wall, as stretchers and headers; the English bond is made by laying all the bricks in one course as headers, and all those of the course immediately above it as stretchers; but in both cases care is taken that no vertical joint shall be carried through two consecutive courses, and that the face of the wall shall be carried up vertically, or in regular batter, when the face is not perpendicular. The large bricks of the Romans were, however, used under rather different conditions from those prevailing in modern buildings; for they were in fact used as bonding-courses in the midst of a large body of rubble masonry, in the majority of cases, and therefore they did not require the same minute attention to the arrangement of the joints which is necessary when the mass of a wall is composed solely of small, regular-shaped materials. When the Romans used bricks exclusively, they seem to have adopted rather what we should call the old English, than the Flemish bond. In many of the Roman brick arches, bricks radiating to the centre have been used; and indeed that wonderful people was evidently as well acquainted with the art of making moulded earthenware as are the best manufacturers of our own days. It would appear, also, that their engineers were aware of the fact that the strength of brickwork depends more upon the mortar used in its preparation, than it does upon the resistance of the bricks themselves; for they paid great attention to the composition and to the manipulation of their mortars, as we shall have occasion to remark in detail, in the articles CEMENT, LIME. In the middle ages, it may be added, the use of bricks took place under nearly the same conditions as in earlier periods, so far as the mode of placing them in the work is concerned; but the architects of Northern Italy and Germany obtained new and striking effects of colour by the use of moulded and glazed bricks; whilst in France and in parts of England architectural decorations were obtained by cutting the bricks themselves. The bricks which admitted this treatment were of course the fine grained, uniform, and rather soft bricks; but when proper precautions have been observed in placing them, time and exposure have produced far less effect upon their surfaces than might have been expected.

As the quality of bricks varies within so wide a range, and, as we said before, the quality of the cementitious material used with them limits the practical strength of this description of work, it may be dangerous to attempt to lay down any absolute rules with respect to the resistance brickwork can offer. Mr. Edwin Clark, however, in the course of his experiments at the Menai Tubular Bridge, ascertained that the average resistance of brick-work, set in Roman cement, to an instantaneous effort of compression, was equal to about 33.5 tons upon the superficial foot; and in the great St. Rollox chimney, near Glasgow, the weight actually brought upon the lower courses of brick-work is nearly 16 tons 14 cwt. per foot. In the trials to which some of the brick viaducts of the Havre and Rouen line of railway were exposed, after the fall of the Barentin Viaduct, the crushing weight thrown upon the piers of brick-work, set in ordinary chalk-lime mortar, was made equal to about 6.4 tons on the superficial foot; but at the time this trial was thought to be exaggerated, even though no accident ensued from it. M. Vicat carried on, some years since, a series of experiments on the subject of the strength of brick-work; and from them it would appear, that the instantaneous and the safe permanent resistances, per superficial inch, according to the nature of the mortar employed, may be considered to be as follows:—

	Instantaneous.	Permanent.
Chalk lime and common sand, fourteen years old	270 lbs.	81 lbs.
Ordinary hydraulic lime	1050 "	315 "
Eminently hydraulic lime	2043 "	613 "

These values are high; but if care be taken in the execution of the work, they may be adopted as maxima. M. Vicat also made experiments upon the resistance of similar materials to an effort of extension, and he deduced from them the following table:—

	Instantaneous.	Permanent.
Chalk lime and common sand, as before	57 lbs.	17 lbs.
Ordinary hydraulic lime	129 "	39 "
Eminently hydraulic	213 "	64 "

The resistance to an effort of torsion is usually considered to be equal to about $\frac{1}{5}$ of the resistance to compression.

A very important practical observation, with respect to the use of bricks in foundation works, is, that the under-burnt bricks are more easily acted upon by external agents, such as water containing carbonic acid gas in solution, than are either the unburnt clay or the thoroughly burnt bricks. It follows, therefore, that in such positions only the hardest and most perfectly burnt bricks should be used, especially if

the water attacking the foundations should be frequently changed; but if the water should be stagnant, it may happen, when the bricks contain a large proportion of soluble silica, that the free lime of the mortar may form with it a stable combination which will greatly increase the strength of the mass. This peculiar action is known amongst working men by the phrase of the brick-work being "water bound;" and it may be observed to occur when rather soft kiln-burnt bricks have been used in permanently damp ground, in connection with rich lime mortar. In tidal works, however, or in positions where the water is frequently renewed, none but the hardest bricks and the most energetic cements should be used; and this precaution must always be adopted in those parts of a building exposed to alternations of dryness or of humidity.

Brick-work, in the neighbourhood of London, is reckoned at so much per rod, or the unit of bricklaying accounts is the rod of 272 feet superficial, of work 14 inches thick; that is to say, of $11\frac{1}{2}$ cubic yards, or 306 cubic feet. Assuming that the bricks are laid with a close joint, to a gauge of four courses to $11\frac{1}{2}$ inches in height, there will be required 4500 stocks and 71 cubic feet of mortar in a rod. The weight of a cubic foot of brick-work in cement is about 105 lbs., and that of a cubic foot of brick-work in mortar is about 98 lbs. In most tables of specific gravities, that of brick-work is quoted as being 1.87; but this is rather in excess of the real facts of the case.

Brickmaking by Machinery. We must now attend to those remarkable modifications of the processes which have been due to the introduction of machinery. Rapidity of production is not the only reason for the adoption of machines. It has been found in some of the brickwork of railway arches and tunnels that the outer or most exposed bricks have a tendency to decay, from the alternations of temperature and moisture to which they are subjected; and it is as a means of lessening that tendency, by increasing the solidity and closeness in the adhesion of the clay of which the bricks are formed, that machine-made bricks have often been recommended.

About 1836 Messrs. Heaton of Birmingham, who had before introduced a mode of tempering the brick-clay by rolling, devised a machine for moulding the bricks as well as preparing the clay. The machine consisted of a horizontal wheel, round the margin of which were arranged a number of brass moulds, the proper size and shape for bricks. The bottom of each mould was loose and moveable vertically by a small apparatus beneath, connected with a little wheel. The wheels of all the moulds worked on a circular railway, having such an inclination as to leave the bottom of the mould in its proper position when at one part of the circular course, but lifting it up to the top of the mould when the latter had travelled round half a circle. When any of the moulds came to a particular part of the circuit, a loose board was put into it by an attendant, a stream of water was forced into it from a forcing pump, and the tempered clay, coming from the rollers through which it had been pressed, and passing through a hopper, was forced by a plunger into the mould; then, the mould advancing one step in its circuit, a knife-edge sliced off all the superfluous clay, and rendered the upper surface smooth. The mould continued to travel on in its circular path, and its bottom, with the newly-made brick, became lifted up gradually; until, by the time the half-circuit had been made, the brick was lifted wholly out of the mould: a man then took off the brick, and prepared it for burning in the usual manner. It was a necessary feature in this arrangement, that all the moulds were in different states or stages at any one instant of time; half of them contained bricks, half contained none; one was just receiving its supply of clay, while another, exactly opposite, was yielding a finished brick to the hands of the workman; and of the rest, some were having the loose bottoms slowly raised to elevate the bricks resting on them, while others were gradually resuming the form fitted for the reception of clay.

In 1838 M. Terrason introduced a mode of making bricks differing considerably from the above. There are three parts of the apparatus, destined respectively to kneading the clay, moulding the bricks, and transporting them when made to a yard or depository. In the first process, two horses, attached to the two arms of a lever, work some revolving cutters in a cylinder, by which the clay is thoroughly kneaded. The second machine, destined to mould the bricks, is placed near the former one, and receives the fillet of clay as it exudes from the cylinder. The mould for the bricks is simply an oblong channel or hollow frame, having neither cover nor bottom, but one roller working above it and another below it. The clay enters this trough, the width and height of which give the proper width and thickness of a brick; while the two rollers, pressing the clay above and below as it enters, give the proper flatness of form to the upper and lower surfaces, compress the clay into a solid consistency, and expel the superfluous portions. The clay, in fact, passes through a kind of rolling-press. When the oblong trough has been removed, by reciprocating action given to it by machinery, from this press, the board on which the clay rests becomes released from the side-boards of the trough; then on passing under a particular part of the apparatus, the oblong fillet of clay is cut into ten or twelve bricks, by the descent of as many wires stretched across above them. In the third machine, by means of a long row of cylinders working on an inclined plane, the board of bricks is carried to any convenient distance, where they are deposited previous to burning.

In the same year another machine was invented by Mr. Jones, in

which the clay, being mixed with a less quantity of water than usual, was kneaded in a pug-mill to a stiffer consistence than ordinary, thereby rendering a shorter period for drying sufficient. The rate at which the bricks were made by this machine was stated to be from one to two thousand per hour.

From about the year 1840 the suggested or patented improvements in brick-making have been very numerous; but they do not call for lengthened description. In Mr. M'Nab's method there is a sliding-frame beneath the bottom of the mill in which the clay is ground; and this frame contains two brick-moulds, so arranged that while one of them is under an opening in the bottom of the mill, receiving clay from thence, the other is outside the mill delivering a moulded brick; the two moulds being alternately placed in communication with the mill. The bottom of each mould consists of a moveable bed, which, when the mould has arrived outside the mill by the movement of the frame, forces the brick up out of the mould, to be removed by an attendant. Another method introduced about the same time, had a peculiar adjustment whereby a screw forces the clay out of the mould, and wires descend to cut it into bricks. A method patented by Messrs. Cook and Cunningham is on a different principle. Here a sliding mould-frame, containing two moulds, is applied to the side of the mill in which the clay is prepared. The clay is forced, by the rotation of arms within the mill, through an opening into a box; and a piston working in this box presses the clay into one of the moulds in the sliding frame. When one of the moulds has been thus filled, the frame moves forward, which brings the other mould under the box, while the first mould is carried over an empty moveable mould placed on a table; a piston presses the brick into the empty mould, and the mould thus set free returns to receive a fresh supply from the box. The mode is thus so far a continuous one—that while one mould is emptying its contents into the moveable one, the other is receiving a fresh supply at the box; while a boy receives the moulded bricks from the moveable mould as fast as they are deposited in it. Mr. White's patent, of the same year, related principally to an improvement in the mode of supplying the clay from the mill.

Mr. Gibbs has proposed a method in which both the materials of the bricks and the mode of manufacture are taken into account. He proposes to use Merstham sand or pulverised Merstham sandstone, combined with London clay or pipe-clay; in proportions varying according as bricks, tiles, or pottery are the object of manufacture. The mode of making bricks under the patent embraces two or three modifications, of which one consists in rolling the clay out into a sheet of uniform thickness, then cutting it by machine-worked knives or wires into brick-shaped pieces, and compressing these by a separate machine. An American method introduced more recently by Messrs. Beach and Lukens, seems to be founded mainly on the plan of Messrs. Heaton, but to contain a provision for transporting the bricks to any convenient spot by means of an endless belt.

Mr. Prosser has introduced a method of making bricks, tiles, and small articles of earthenware, from earth or clay almost in a state of dryness, by intense pressure in metallic moulds.

The *weight* of bricks, made by any method, is an important matter in relation to the purpose for which they are to be applied. In a conversation at the Institute of Civil Engineers, after the reading of a paper relating to bricks, several engineers objected to the use of bricks made wholly by machinery, on the ground that their extreme compactness made them heavier and more costly than common bricks, and delayed their drying. Mr. Hunt has, for this reason, brought into use a contrivance where hand-power and slight pressure are substituted for machine-power and heavy pressure. The decision as to the general introduction or not of machine-made bricks, will probably depend, as in most other cases, on the relative expense in comparison with the hand method; hitherto they have been rather too costly. At Roorkee, in the north-west of India, where extensive engineering works have been carried on, requiring a hundred million of bricks, great economy has been found to result from the introduction of a brick-making machine from England.

It may be well to notice one peculiar manufactured article, which receives the name of a brick from its shape, and not from its use or purpose. A manufacture peculiar to, and constituting a staple trade of Bridgewater, is the fabrication of that kind of white brick known as *Bath Brick*, so largely used in knife-cleaning; this branch of industry gives employment to many of the inhabitants. These bricks are formed of the sediment or sand of the river Parret, cast into moulds and dried.

Bricks, like many other articles of manufacture, underwent many varieties in the rate of duty imposed. The tax was first laid in 1784, at 2s. 6d. per thousand. In 1794 it became 4s., and in 1803, 5s. In 1835 the duty was increased to 5s. 10d., for common bricks of ordinary size. In 1803, bricks of larger size were taxed to the extent of 10s. per thousand. Polished bricks were 12s. 10d., and large polished 24s. 2d. The words of the Act referring to glazed bricks were "smoothed and polished;" and so strict were the revenue officers, that bricks struck with a bat or on a table to straighten them if warped, were considered to be "smoothed and polished," and were charged with the extra duty. At length, in 1850, this vexatious duty was removed; and a beneficial result was almost immediately perceived, by allowing scope for the exercise of inventive talent. The maker, under the old law, had no

encouragement to depart from the ordinary size and quality; seeing that the duty rapidly increased if the bricks were either larger in size or superior in quality. Just before the duty was repealed, it was charged on about 2000 million bricks annually; there are now no means of determining how many are made.

BRICKWORK. Brick walls are of various thicknesses; from four and a half inches to three or four feet, according to the nature and purpose of the structure. The most usual dimensions are four and a half inches or half brick; nine inches or one brick; fourteen inches or one and a half brick; and eighteen inches or two bricks. Except in large public works, walls are seldom built more than four bricks thick. In good work three bricks are well bonded together.

The word *bond* is applied to the mode of laying bricks side by side, and one on another, so as to produce the greatest strength, and the most symmetrical appearance. There are four kinds of bond—besides exceptional kinds which need not be noticed here—in general use in laying bricks; called English bond, Flemish bond, herring bond, and garden-wall bond. *English bond* consists of bricks laid lengthwise on the length of the wall, and crossed by bricks laid with their breadth on the wall. The former are called stretching courses, and the bricks stretchers; the latter are heading courses, and the bricks headers. This bond is much used in hydraulic engineering. *Flemish bond* consists in laying a header and stretcher alternately in the same course. This bond, which is considered by bricklayers the most beautiful, is not so effectual as the English bond. To unite more firmly the Flemish bond brickwork, especially in thick walls, and to remedy the weakness of the stretching courses, the bricks are often placed at an angle of forty-five degrees parallel to each other, and reversed in the alternate courses; this is done in the centre or core of thick walls, and is called *herring-bond*. It is advisable only to use this diagonal brickwork occasionally; because, though the bricks in the core have sufficient bond, the sides, on account of the triangular interstices, are very improperly tied to the core. Flemish bond is, moreover, varied according to the width of the openings in the wall or front of a house. The reveals of windows are bonded every alternate course, with a closure or quarter brick and a half brick. The reveals of doors are terminated with a half brick and closure. *Garden-wall bond* consists of three stretchers and one header in nine-inch walls; but when fourteen inches thick, the Flemish bond is used. In English bond, it is to be observed, that as the length of a brick is nine inches, and its breadth four and a half, it is the practice to prevent two perpendicular joints from falling over each other, at the end of the first stretcher from the corner header, by the introduction of a closure, or by a three-quarter brick or *bat* as it is technically called, instead of a stretcher at the corner.

The most difficult work for the bricklayer to execute is the groining or intersection of arches in vaults, where every brick has to be cut to a different bed or angle. This and the arches called gauged arches, either circular or straight, cut with the axe and rubbed on the banker or table, and afterwards set in lime only, called putty, require the neatest workmanship. Some straight arches are made roughly; that is, the bricks are inclined each way, parallel to each other on the respective skewbacks or shoulders of the arch, until the soffit-ends of the bricks touch, when the vacant space at top is filled with two bricks forming a wedge: this arch, like other straight arches, is constructed on a camber slip, or piece of wood slightly curved on the upper side, and serving as a centering.

The bricks for rubbed or gauged arches are cut with radiating lines. Those for cambered or straight arches are cut by the manual skill of the workman; and the lines do not radiate exactly to one centre, like the bricks in semicircular gauged arches. The following is the method adopted by bricklayers in cutting the straight arch: The straight arch, so common in houses in London, is first drawn out the

Mould.

[Cut of the mould with the bevels set off upon it.]

a represents the point at the top line of the mould, being a guide for the brick; *b b*, the angles set off by the bevel.

full size on a board; the top part is a straight line; the lower, the curved line of the camber-slip, a segment of a circle; and the sides, the inclination of the skewback of the arch, which is usually inclined about seven inches and a half from the upright of the reveal. The top and the bottom lines are then divided into an equal number of equal parts, and lines radiating are drawn as shown in the cut. The joints follow the curve of the camber-slip. The curved line at the bottom given by the camber-slip is cut by means of the bevel; every

angle of each brick being different, they are copied by the bevel, and set off in succession on the mould and numbered, so that for the rest of the operation, the workman has only recourse to the mould.

A larger, or what is called an irregular, segment is cut in the same manner. A semicircular arch being struck from one centre requires but one mould, without the aid of the bevel, as all the bricks are alike and have their ends at the same angle. All arches, it should be observed, are constructed on centerings of wood. In straight arches the camber-slip answers the purpose of a centering. Elliptical arches are cut like straight and semicircular arches, the ends like semicircular arches, and the centre like camber arches. Corbelling, or a projecting of brickwork, is often practised to gain space for flues and over corners of narrow streets.

In steining wells it is usual to employ brickwork where the soil is loose. For this purpose a centre is required, made with circular rings of wood boarded round the outside; upon these rings the bricks are laid. As the digger excavates the ground, the centre with the brickwork sinks and another is laid upon it till the whole work is completed.

Mortar is the common medium employed in the execution of brickwork. This mortar, in the neighbourhood of London, is composed of lime, gray or white, but gray or stone lime is the better; it is mixed with river sand, sea sand, or road sand, in the proportion of one of gray lime to two and a half of sand, and one of white or chalk lime to two of sand. In dry weather and for firm work the best mortar should be used, and the bricks should be wetted or dipped in water as they are laid, which makes them adhere firmly to the mortar. Brickwork in drains and foundations, where it is liable to be constantly wetted, becomes so firmly united with the mortar as not to be separated without the greatest difficulty.

In building walls, they should be carried up level all round simultaneously, and not one part higher than another, lest in the shrinking there should be a settlement, which would cause the parts to separate. In laying the foundation of walls the first courses are always laid broader than the wall intended to be carried up; these courses are called the footings; and the projections, called set-offs, are generally two inches in projection. Garden-walls are usually built with piers, projecting four and a-half inches from the face of the work at every ten or twelve feet. These piers are turned in at the top like buttress-heads, and the top of the wall is finished with a course of brickwork on edge.

When new walls are to be attached to old it is usual to cut a chase or draw a brick at every other course in the old work and *tooth* in the new work. When it is intended to add walls to other buildings these toothings are left. The flues for chimneys are twisted to prevent their smoking; they are always chalked on the wall of a house to which another is intended to be added.

A rod of brickwork was originally taken from the standard of 16½ feet square, and consequently consisted of 272½ square feet; but as the ½ was found troublesome in calculation, 272 superficial feet has been adopted as the standard for a rod of brickwork. The following is the method in practice for calculating the number of rods and feet in a brick wall, if of the standard thickness, which is 13½ inches, or a brick and a half. Multiply the length by the height, and divide by 272, which will give the rods; if it is more or less than the standard thickness, multiply the surface by the number of half-lengths of bricks in the thickness of the wall, divide the product by 3, and the wall will be reduced to the standard, which, if divided by 272, will give the work in rods: or if the work is cubed, it must be divided by 306 to reduce it to rods, &c. A rod of standard brickwork set with mortar will require 4500 bricks upon an average: the mortar required for the same is 1½ cwt. of chalk or white lime with two loads of sand, or 1 cwt. of stone lime with 2½ loads of sand. In walls a foot of reduced brickwork requires 17 bricks. A foot superficial of gauged arches requires 10 bricks. A yard of paving requires 82 paving bricks, or 48 stock bricks, or 144 Dutch clinkers laid on edge, or 36 bricks laid flat. The weight of a rod of brickwork is calculated to be 15 tons 7 cwt. 2 qrs. 1 lb., in the following quantities:—

	tons.	cwts.	qrs.	lbs.
4500 bricks	9	18	0	9
81 cubic feet of sand	3	8	3	20
40 ft. 6 in. of chalk lime	2	0	2	0
	15	7	2	1

Among the most remarkable specimens of ancient brickwork are the masses on the Palatine hill and the baths of Caracalla. The Roman brickwork in large works is excellent: the bricks are very hard, and so firmly cemented, that they cannot be separated without the greatest difficulty. Great care has been shown in the execution of the work; and one building, still existing near the grotto of Egeria, has pilasters, cornices, modillions, dentils, and other ornaments finely cut in a yellowish brick closely cemented together and still in high preservation. The most recent specimens of ancient Roman brickwork are the walls which surround Rome: there are also many specimens scattered throughout Italy. The bricks being generally thin and of the nature of tiles, this circumstance diminished the difficulty of constructing arches, of which the great arches of the Temple of Peace in the Forum Romanum are remarkable examples. The Tauk Kesra at

Ctesiphon (about 18 or 20 miles from Bagdad) is perhaps the largest ancient brick arch existing, being a semicircle 85 feet wide, 106 feet high, and 150 feet long.

The worst bonded specimens of brickwork executed by the Romans are those formed of triangular bricks filled with rubble. The reticulated work, which is constructed with stones, is often bonded with courses of brickwork. In Pompeii columns constructed with bricks have been discovered: in this city the brickwork of the public buildings has been very accurately executed.

The brick dome of Santa Sophia at Constantinople is made of porous bricks, light enough to float on water. The brick towers of Bologna are stupendous piles of brickwork. The brickwork in Holland is very accurate. There are many curious brick fronts in Germany, especially in Hanover, and some architectural display in brickwork appears in several of the smaller Italian towns. But the most singular and beautiful brickwork is found in North Prussia, in the Marien Kirche at Brandenburg, the castle of the Teutonic knights, and a variety of other buildings.

Brickwork was not common in London until after the great fire of 1666. There are early specimens of brickwork in some of the old baronial mansions, in which the chimneys are the most conspicuous features. But few of these houses are of greater antiquity than the time of Henry VII. and VIII.; and most of them date about the reign of Elizabeth. Hampton Court, built by Cardinal Wolsey, is a specimen of good ancient English brickwork. One of the most elaborately carved specimens of English brickwork with which we are acquainted is a tomb in the church of Wymondham, Norfolk, which is in the early Italian style, covered with grotesque ornaments. The practice of carving cornices, &c., in brick continued till about a century ago, when it ceased, owing to the more frequent use of stone. Inigo Jones used brick-moulded cornices in some of his structures.

It may safely be asserted that London now contains more brick structures than any other city in the world—so abundant is the supply of clay, and so distant are the quarries of stone. As a general rule, the private houses do not display any great excellence in brickwork; perhaps St. James's Square, and a portion of the buildings at Kensington Palace, are among the best. Several of the vast warehouses recently built in New Cannon Street present fine examples of brickwork, dressed with stone. Many of the new churches exhibit a careful use of red, yellow, and white bricks—the manufacture of which has greatly increased since the removal of the duty. Vast systems of

brickwork are comprised in the sewers of London; and still finer examples will probably be afforded by the great intercepting drainage now (1859) just commencing. The Thames Tunnel is a large and fine specimen of brickwork. Still more extensive are the viaducts of brick arches belonging to the various railways which enter the metropolis. The very perfection of brickwork, probably, is exhibited in the lofty factory chimneys, some of them 400 feet high, in Lancashire, Cheshire, Yorkshire, and around Glasgow.

BRIDGE. A construction by means of which a roadway or a foot-path is carried across a river, or other piece of water. In common language bridges differ from aqueducts, inasmuch as the latter convey water only; and from viaducts, because viaducts usually are erected in deep valleys wherein the watercourse occupies but a very small portion of the space traversed, whereas bridges are essentially erected in the watercourses it is desired to pass.

Although unquestionably the necessity for erecting some means of permanent communication between the respective banks of large rivers, must have been felt at an early period in the history of civilised nations, it was not until a comparatively late one that the art of bridge building can be said to have assumed any definite character. The Greek historians, indeed, mention the erection of very important bridges by Semiramis, Darius, Xerxes, Pyrrhus; and in Egypt, the irrigation canals must have rendered it necessary to construct many such passages. But it would appear that the style adopted in all these constructions was of the rudest and most unscientific character; and, in fact, it consisted simply in the erection of piers upon the tops of which were laid horizontal beams of timber, or large flat stones. During the monarchy and the early days of the republic of Rome, bridge building remained in this rudimentary state; and even subsequently to the completion of the Cloaca Maxima, wherein the principle of the arch is boldly and successfully applied, the earliest of the bridges over the Tiber was constructed of timber as above described. This would be the more singular if, as has been asserted, Tarquinius Priscus, during whose reign the cloacæ were made, actually built a stone bridge over the Tevere; but inasmuch as there are reasons for doubting the correctness of this story, it would be safer to consider that the erection of the first stone bridge of large span, was that of the Ponte Rotto, or the Senator's Bridge, built about the year 127 B.C., by Caius Flavius Scipio. This was rapidly followed by other works of the same description, such as the Ponte Mole, Janiculum, Fabricius, Sestius, &c.; and directly the Roman empire was definitely

50 100 200 feet.

Pons Senatorius, now Ponte Ratto, restored.

Alcantara.

established under Augustus Cæsar, the series of wonderful engineering works connected with the formation of roads, and the establishment of water supplies, which still challenge our admiration, were commenced. In fact, arched construction was essentially a Roman invention; and it was not until their civilisation had distinctly developed itself that the art of bridge building could be said to exist. It is true, however, that the Assyrians and Egyptians had applied the principle of the arch long before Rome exhibited any indications of its future greatness, as has been shown under ARCH, vol. i. col. 486.

It has been asserted that the Chinese have, for countless ages, possessed many of the arts and sciences which Europeans have only acquired within a few years and after a tedious and painful series of

experiments. Amongst the rest, it is said, that the art of bridge building was practised amongst them, at periods long antecedent to its cultivation in the West; and the bridges at Fou-tcheou-fou and at Suen-tcheou-fou are quoted amongst their earliest works of this description. There are no reliable accounts of these structures, but from the little which can be gathered from the travels of the Jesuit missionaries it would seem that the Chinese, at the time of their erection, were not able to execute great bridges in a superior style to that adopted by the Egyptians, Assyrians, or Greeks; for those above-named were simply formed by laying large horizontal stones upon upright piers. It is true that in China, bridges are said to exist in which pointed, semicircular, polygonal, and semi-elliptical arches are

to be found; but the date of these works is unknown; and from the very equivocal character of the chronology of the East, there must always prevail a degree of uncertainty with respect to the authenticity of the claims of those nations to extreme antiquity. Without therefore deciding upon the question of the claims of the Chinese to the discovery of the art of bridge building, we may content ourselves by asserting that it is to the Romans that Europeans owe that useful art, and that the models they left have served as starting points to the efforts of modern engineers.

Indeed during the more prosperous days of the Roman empire, the attention of the central administration was directed, with singular energy and perseverance, to the perfection of the means of internal communication: and the making of roads, of which the construction of bridges formed a necessary part, was carried to a very remarkable degree of perfection. The bridges of Rome itself have been already alluded to; but although numerous, and it may be added bold in

Vicenza.

their design and execution, they fell much behind the bridges erected in the provinces in both those qualities. Thus the bridge of Narni had a centre arch with a chord or span of not less than 131 feet; and the span of the centre arch of the bridge of Alcantara is 101 feet: but the bridge erected by Trajan over the Danube was the master-piece of Roman engineering of this particular description. It consisted of 20 semicircular arches of 180 feet 5 inches span, springing from piers 64 feet wide on the line of the axis, by 85 feet 3 inches thick, at a height of 46 feet above the water-line of the river in its

normal state. Unfortunately the later emperors were not able to carry on the vigorous policy of Trajan, and the bridge he had thus built at so great an expense to enable his own armies to attack the barbarians of Dacia, was so soon made use of by the Dacians themselves to attack the Roman dominions, that Adrian thought it advisable to destroy the glorious work of his predecessor. In France, Spain, Italy, Greece, Asia Minor, and even in Northern Africa, however, the Roman bridges have been fortunate enough in many instances to escape the ravages of time and of war; and the bridges of Vicenza, Boisseron, Sommiere, St. Chamas, &c., may still be referred to as illustrating the practical and æsthetical feeling of the Roman architects in designing such works.

During the stormy interval between the periods of ancient and modern history, the art of bridge-building shared the fate of the other material expressions of civilisation. It was occasionally practised, both by the architects of the Lower Empire, and by the more refined of the conquerors of Rome; indeed, some of the bridges of the time of Justinian, such as the aqueducts near Constantinople, or the restoration of the Ponte Salaro, were nearly as striking works of their kind as were the provincial bridges of the earlier Roman emperors. The extraordinary aqueduct of Spoleto has been usually attributed to Theodoric the Goth, who reigned, however, about the commencement of the 6th, instead of about the middle of the 8th century, to which latter period the construction of this aqueduct has been assigned; with about as much correctness, be it observed, as in the case of its author, for the style of architecture adopted in it certainly did not prevail until about 500 years later than its supposed erection. Whatever were the date of the Spoleto aqueduct, there are no authentic records of the erection of stone or brick bridges of any kind subsequent to the time of Charlemagne until about the commencement of the 11th century, when the order of the Frères Pontiers, or du Pont, was established, for the express purpose of remedying the defective state of the modes of communication, arising from the want of new bridges or the destruction of the ancient ones. The Pont St. Esprit over the Rhone, the bridges of Ratisbonne and of Avignon, were amongst the earliest works due to the efforts of this useful association; or, perhaps, as the authenticity of the existence of the separate order has been questioned, it would be more correct to attribute the execution of these bridges to the civilising influence of the Church in the middle ages. Slowly the civil authorities of western Europe followed the example set them by

Ponte Corvo.

the Churchmen; and we read of the erection of the old bridge at Bow, by the orders of Matilda, the wife of the Conqueror; of old London Bridge, about 1176; the old Bridge of Dresden, the Biddeford Bridge, and the singular triangular Bridge of Croyland, being erected in connexion with many analogous works about the 12th and 13th centuries.

The covered bridge over the Ticino at Pavia, and the long causeway and bridge of Orense in Galicia, Spain, are amongst the most remarkable structures of the middle ages; and they were worthily followed by the Ponte Corvo, over the Melza; the Pont Notre Dame, at Paris; the covered and the marble bridges of Florence; the Rialto of Venice;

the Ponte della Trinita, also of Florence; the Pont Neuf, of Paris; the bridges of Saintes, Maestricht, and des Tuileries. About the commence-

Ponte della Trinita.

ment of the 18th century, however, the greatest movement in the art of construction, as applied to the means of intercommunication, seems to have taken place; and the establishment of the corps of the Ponts

et Chaussées in France, about 1720, must be considered to have given a more scientific and organised direction to the study of the engineering profession, especially in that country to which all Europe then looked for instruction and example. The bridges of Blois, Orleans, Tours, Mohlins, and Saumur, were amongst the first works produced by the above-named body of engineers; and they were followed in rapid succession by the very beautiful structures erected by Peyronnet at Neuilly, St. Maxence, and the Pont de la Concorde, at Paris. Our own countrymen were not far behind their neighbours in the erection of these useful structures; and the bridges of Blenheim, Westminster, Blackfriars, Perth, Coldstream, Hexham, Kelso, &c., may fairly be compared with any similar works of France, or of any other country. But the

Coldstream.

introduction of cast iron amongst the ordinary building-materials of bridges, by Mr. Pritchard of Shrewsbury, about the year 1775, in the erection of the Coalbrookdale Bridge, laid the foundation of a new and singularly valuable style of construction. The example set by Mr. Pritchard was followed by Thomas Wilson, at Sunderland, in 1795; and shortly afterwards cast-iron was largely applied, both in bridges and in aqueducts, by Telford and his contemporaries in England. The German and Swiss engineers of the 18th century executed some remarkable specimens of carpentry, and some stone bridges of considerable dimensions. Amongst the former may be mentioned the Schaffhausen Bridge, erected in 1770, by Grubenmann; amongst the latter, the Dresden, Nossen, and Nürnberg bridges; attention will be called hereafter to some of these works.

Subsequently to the commencement of the present century, the

wonderful progress of civilisation (promoted by the improvements effected in the means of locomotion; firstly, by the introduction of carriage-springs, by the development of the canal system, by the application of steam to navigation, and finally by the execution of the railways which now intersect every part of Europe) has caused the art of bridge-building to advance with a rapidity hitherto unexampled. In proportion also with the improvement of the art itself, it would appear that the requirements of public authorities have increased; and thus the genius and skill of the engineers (as the members of the architectural profession who especially directed their attention to the construction of bridges and analogous works began to style themselves, by way of distinction) were taxed to the utmost. It was to these facilities for local communications that we owe the introduction of the suspension or chain-bridges; later still, the wrought-iron girder and

tubular bridges; and the lattice bridges, whether of wood or of iron, have also been invented to satisfy the constantly increasing requirements of the age. Many of the bridges erected in the course of this century are as remarkable as works of art as they are as works of construction; and it may suffice here to mention, in our own country, the Gloucester,

Dean's Bridge Viaduct, Lune Aqueduct, Llangollen and Pont-y-Cysyllte Aqueducts, London and Waterloo stone bridges, Southwark iron bridge, Menai, Hammersmith, Hungerford, and Pimlico suspension bridges, the High-Level Bridge, the Britannia, Conway, and Saltash tubular bridges, to illustrate the progress of the art. Amongst our neighbours, also, a

similar activity may be observed to have taken place as among ourselves; and the gigantic works executed in France, Belgium, Germany, Switzerland, Italy, and even in Spain, within the last few years, prove that those nations are as deeply impressed with the necessity for providing at almost any cost the means of easy and uninterrupted locomotion, which is indeed the end bridges are designed to subserve. The inhabitants of the United States have not been behind in this

race of improvement, and we owe to them several of the boldest innovations in the art of bridge-building, to which they have been driven by the peculiar conditions of their country. The Bridge of Trenton over the Delaware, the Upper and Lower Schuylkill bridges near Philadelphia, the great Portage Viaduct, and the Niagara Suspension Bridge may challenge comparison with any similar works erected in Europe.

Amongst practical bridge builders the following terms are generally applied to the various descriptions of bridges, and to their various parts; and the several meanings thus assigned will be attributed to the respective words in the sequel of this article:—

A bridge is said to be either a *culvert*, when it conveys a small stream of water under an embankment, or a raised causeway; or a *foot bridge*, when it is only designed for the passage of foot travellers; or a *bridle bridge*, when it is large enough for the passage of led horses; or an *occupation bridge*, when large enough for the passage of farm waggons, and exclusively reserved for the use of the neighbouring landowners. Public road bridges may be either *fixed*, *moveable*, *flying*, or *floating*; and according to the resource of the country wherein they are erected they may be constructed of stone, brick, wood, or iron; or again they may be constructed upon the principles of *suspension*, or of the application of the built, or girder beams. The extreme masses of masonry constructed to resist the thrust of a series of arches, are called the *abutments*; whilst the intermediate points of support of such a series are called *piers*. The lower surface of an arch is called the *intrados*, and the upper surface its *extrados*; the stones themselves which constitute the ring of an arch are called the *voussoirs*, and the central one is distinguished by the name of the *keystone*. The *haunches* of an arch are those portions respectively midway between the keystone and the *springing*, or *skewback*; and the filling in above the arch, to the underside of the roadway, is called the *spandril*, or the *spandril filling*, as it may be upon the face, or in the interior of the work. The construction between two piers, or between any two points of support, is called an *arch* in stone, brick, or cast-iron bridges; but a *bay*, in timber or wrought-iron ones. The distance between the points of support of a

bay, or arch, is called its *chord*, or *span*; and the vertical height from the underside of the centre of the intrados to the horizontal line passing from the respective springings of the arch, is called the *versed sine*, or *rise*; in the case of beams, the rise is, however, commonly designated the *camber*.

The first important point to be settled in designing a bridge is, the water way absolutely required under the most unfavourable circumstances of the particular case. This dimension will depend, 1st, upon the area of the district contributing to the stream; 2nd, upon the quantity and conditions of its rainfall; 3rd, upon the configuration, and the geological character of the watershed whose drainage is intended to be passed under the bridge. Every geological formation, in fact, parts with the excess of the rain which may fall upon it (beyond the quantity absorbed by the ground, or by the vegetation), under circumstances varying with the greater or less inclination of its surface, and with the accidental interferences that surface may offer to the escape of the surplus waters, whether arising from the state of the upper strata, the outlines of the valleys, or the vegetation covering their sides. Porous limestone, sandstone, or sandy strata, for instance, yield streams which are, generally speaking, constant in their volume, and are rarely visited by floods; whilst, on the contrary, the dense, non-absorbent granites, slate rocks, marbles, clays, and loams, give rise to streams which are notoriously capricious in their flow, and liable to serious and unexpected floods. It is, moreover, to be observed that the denser and non-absorbent formations usually occur in mountain chains, at considerable elevations above the sea level, and that their outlines are sharp and precipitate; whilst those of the absorbent strata are for the most part gently undulated. It thence happens that

not only is the rainfall upon the former more copious than that upon the latter, but that it runs off with greater rapidity. From this it also follows, that the water way to be given to bridges in districts composed of the non-absorbent strata, must be made greater than that which would suffice for the porous ones. M. de Belgrand, in an article inserted in the 'Annales des Ponts et Chaussées,' stated that the granitic rocks, being usually the most precipitous, were those which required bridges with the largest water way; but that with an equality of fall, the liassic formations required nearly the same, if not rather larger, dimensions; the clays, whether of the secondary, or post-tertiary series, were considered by him to require bridges somewhat smaller; whilst the oolites and the chalk admitted the construction of bridges with comparatively speaking small water-ways. It is observed, however, by M. de Belgrand that these theoretical rules must be modified by the distance the water has to flow before it arrives at the bridge. He stated that from the practice of the bridge builders in the valley of the Seine, the proportions of the water way to the area of the feeding ground of the streams, might be reckoned as follows; but evidently the conditions of the rainfall of the particular district under examination must affect the whole of this question, and the results indicated by M. de Belgrand must only be considered to show the relative proportions prevailing in the bridges of some parts of central Europe.

Very steeply inclined liassic deposits require a water way, per mile square of feeding ground equal to about $1\frac{1}{2}$ yard deep.

Granitic rocks	$1\frac{1}{2}$ yard deep.
Oxford clay	1.1 "
Common clays	.72 "
Chalk, or Oolites, only	.03 "

These dimensions are not quite in accordance with those usually adopted in either very flat, or very mountainous districts; for in Holland, it is the custom to make the water way of bridges in the proportion of about 0.15 yard superficial for every square mile of back country; and in many granitic districts the water way is not made greater than in the proportion of 0.45 yard superficial per square mile. M. de Belgrand's observations are, however, the first which have been made in any philosophical or consecutive spirit; and they may be the more safely adopted, because they would rather lead to an error in favour of the stability of the work than otherwise.

But in addition to the consideration of the area of water way to be provided, in order to allow the free discharge of storm or flood waters, it is necessary to provide against the possibility of the bed of the river being affected by the increase in the velocity of the stream produced by the contraction of its lateral dimensions. Whatever changes therefore may be introduced in the shape of the water way of a river, in order to admit of the construction of a bridge, it is absolutely necessary to limit the mean velocity of the stream, at the periods even of its greatest flow, within the following limits, according to the nature of the strata it may flow over (Neville's 'Hydraulic formulæ') :—

25 feet per minute in soft alluvial deposits.	
40 " " clayey beds.	
60 " " sandy and silty beds.	
120 " " gravelly.	
180 " " strong gravelly.	
240 " " shingly.	
300 " " shingly and rocky.	
400 " " and upwards in rocky formations.	

It is essential also to the stability of a bridge that, even in flood times, the water should not rise to the underside of the keystone; and in settling the dimensions of the water way attention must be paid to the contraction of the fluid vein, produced by the various points of support. The interference those points of support produce upon the onward flow of the river gives rise to a species of heaping up of the water, as it were, on the upside of the bridge, and a consequent increase of velocity on the lower side: both of these phenomena, which depend upon local conditions, require to be taken into serious consideration in every case under observation. It follows, however, from their existence that the fewer the points of support of a bridge are, the less interference it will produce with the hydraulic conditions of the stream; and that unless very cogent reasons of economy should exist to induce a preference for small arches, large ones should be adopted. In countries exposed to severe frosts and sudden thaws, it is moreover necessary to guard against any danger from an accumulation of floating ice on the upper side of the bridge; and it is desirable that as far as possible the springings of the arches should be kept above the flood line. This precaution is more necessary when the shape of the arch is segmental, or semicircular, than when it is elliptical; but whatever form be adopted, the danger from floating ice must always be guarded against.

The forms to be given to the piers and to the arches of a bridge will depend upon several practical considerations. With respect to the former, it may be stated that they will depend principally upon the opening of the arches, and the description of resistance they themselves (the piers) are required to offer to the stream, or to the dynamical action of the arches. Upon the up-side of the stream in non-tidal

rivers, and on both sides in rivers susceptible of tidal action, the piers must be terminated by what are technically called *cut-waters*, rising to the extreme height of ordinary floods; and from direct experiments it would appear that the most advisable horizontal section to be given to such cut-waters is that of an equilateral spherical triangle, whose apex is presented to the stream. In so much as the piers alone are affected by the openings, their dimensions and form must depend upon their being made equivalent at least to the vertical effort they must support; and it is only in extraordinary cases that they are made of sufficient dimension to resist the lateral thrust of the arches. In fact, there are few important bridges in existence, erected over large rivers especially, in which the piers would remain upright, if the thrust of the respective arches were not carried over, as it were, through the whole series to the abutments; and if one arch in such bridges were withdrawn, all the others would most probably follow. As to the shape of the arches, that may often depend upon mere economical considerations. Semicircular or segmental arches are executed with the least expense, because, if stone be employed, all the voussoirs can be worked from the same mould, or if brick be employed, the labour of laying can be performed by even the commonest description of workmen. But, on the other hand, arches of either of these descriptions require, as we have seen, that the whole structure of the bridge should be kept at a considerable elevation; and in the case of segmental arches the lateral thrust upon the abutments is greater than in any other form. *Æsthetically*, a semi-ellipse, or a segment subtending an angle of 60° , are unquestionably the most elegant forms; and in large semi-elliptical arches it is desirable that the outline should be struck from a sufficient number of centres to ensure the flowing regularity of the curve. The arches of the bridge of Neuilly were struck from eleven centres.

The most important considerations to be borne in mind in designing a bridge are, that the foundations of the piers and abutments should be sufficiently strong to resist the weight brought upon them, and any accidental effort to which they may be exposed from floods or other extraneous causes. As the functions of the piers and abutments are merely to support the vertical pressures of the arches, and to resist any tendency towards a movement of rotation on their own edges, arising from the lateral thrust of the arches, it follows that the lighter they are, and the greater the area over which they distribute the effort, the less will they load the foundations, and the more satisfactorily will they perform the duty required of them. The positive effort to which they may be exposed is ascertained first by calculating the extreme passing load; then that of the structure above the arch; that of the arch itself; and finally, the dynamical efforts of these various loads. As to the passing load, it is customary to calculate upon 240 lbs. per foot superficial of the whole area in ordinary bridges; and in railway bridges, exposed to the action of rolling loads travelling at great velocities, it will be safer to quadruple this calculation. As to the weight of the superstructure, that is of course ascertained from its mere density and cubical contents; and it may be assumed, practically, to be distributed equally over the arch. The weight of the arch will of course also depend upon its density and its cubical contents; and these may practically be ascertained by making the depth of the crown or keystone equal to from $\frac{1}{20}$ to $\frac{1}{35}$ of the clear span, and tracing the extrados of the arch upon the principle that the vertical depth over any particular point of the intrados shall be equal to the depth of the keystone, multiplied by the cube of the radius, and divided by the cube of the height of the point considered above the chord line. The sum of the above partial weights will act upon the resisting points of a bridge with an effort equal to its total weight multiplied by the leverage; and, consequently, the moment of resistance of those points must be sufficiently in excess of the destructive effort exercised by the load to support its continuous action. In order to secure this condition, the resultant of the ultimate thrust should fall within the vertical line drawn from the foundations of the abutments through their centres of gravity; and the moment of resistance of the abutments, from its gravity alone, should be at least equal to three times the maximum effort to which it may be exposed. Of course, in such cases, the resistance to lateral displacement will be increased by the friction of the materials of the abutments upon their beds; and the tendency of the piers to turn over upon their inner edges will be also resisted by the adhesion of the cement, or mortar, employed. It is essential to observe that the above reasoning pre-supposes that the foundations themselves are able to sustain the whole of the weight thrown upon them; but as the importance of this detail of bridge-building is so very great, it will be essential to dwell hereafter somewhat at length on this part of the art.

The above remarks are made upon the supposition that the arch is in itself an arch of equilibrium, and that it has been constructed with sufficient care and skill to allow of its retaining its form when the temporary support, or *centering*, upon which it was built, shall have been withdrawn. They would hold with equal correctness, however, if the materials of which the arch is composed were of such a nature as to render the assemblage equivalent to a solid beam; and this actually occurs when brick-work set in hydraulic mortar, or in cement, or any other analogous small materials, are used. In either case, the load ultimately thrown upon the arch must never attain such limits as to bring the line of pressure beyond the vault itself, either on the side

of the extrados or of the intrados; for if this should take place, the vault itself is liable to be overthrown, under one or other of the conditions indicated in the previous article, ARCH. It is tolerably well known at present that the theoretical and practical rules adopted by engineers for calculating the thickness of arches, and for settling the form of the extrados, give results which are in excess of those rigorously required; and M. Yvon de Villareau has even taken the pains to indicate the precise degree of waste, to be discovered according to his theoretical rules, in the most celebrated bridges actually executed. In a memoir, 'Sur l'Établissement des Arches de Pont,' Paris, 4to, 1854, that eminent mathematician has treated the investigation of the forms and thicknesses to be given to the vault upon a different system to the one usually adopted; for he takes as the unknown quantities in his investigations precisely those quantities which are assumed in the ordinary theory, and he seeks to determine the forms of intrados and extrados which would secure the greatest stability of a vault intended to support a load whose weight and mode of distribution are previously fixed; as also he supposes that the span and the rise of the arch are fixed. The reasoning upon which he supports his opinions is of the most elaborate description, but it involves the discussion of problems of such extreme complication, that it would be impossible to condense them within the limits of this article. The reader is therefore referred to the original treatise; and for the present it may suffice to say, that M. de Villareau has arrived at the conclusion that, theoretically, the rise of complete arches should be made to vary between $\frac{1}{3}$ and $\frac{1}{4}$ of the span, without attaining either of those limits; and that the rise should approach the proportion of $\frac{1}{3}$ in arches of small spans, and of $\frac{1}{4}$ in arches of larger spans. Semicircular arches, he considers, ought only to be adopted in cases when, as in tunnels, the load may be considered infinite. A series of tables are appended to the memoir, in which are stated the values of the quantities applicable to the elements of the calculations required in the cases of segmental arches, or in semi-elliptical ones; and a section of an arch of the latter form, of 200 feet span, and 53 ft. 3½ in. rise, with a thickness of the keystone not exceeding 6 ft. 2 in., is also given. Such an arch would indeed exceed in boldness anything hitherto attempted; but it is to be observed, that the whole of M. de Villareau's theory depends upon the correctness with which the surfaces of the joints of the voussoirs are originally reduced to their element which meets the curve of the centres of gravity, and the contact is subsequently restored upon equal portions of the plane of the joint on either side of that primitive element, so that the pressure must finally be distributed over the whole of the new joint. These conditions are only attainable with extreme difficulty, for defects of execution, or in the quality of the materials, would materially affect them; and indeed the movements which take place after withdrawing the centres of a bridge, are often of so serious a nature as to render it inexpedient or unwise, to adhere to the results of even the most rigorous mathematical investigations.

In the execution of an arch it is desirable, and indeed almost necessary, that the voussoirs should be in uneven numbers, disposed symmetrically upon either side of the keystone; and if there should be simply a band of ashlar voussoirs upon the edge, filled in with smaller rubble, or brickwork, the joints of the latter must range with those of the bands. Of late years, some very large bridges, such as the Maidenhead bridge of the Great Western railway, or the Pont aux Doubles, at Paris, have been executed entirely of small materials, which, in fact, do not act in any way whatever as arches; for the adhesion of the cement employed converts the whole mass into a solid body, which retains its form through the inherent powers of resistance of the cementing materials themselves. But whether the arch be composed of voussoirs able to move upon their beds, or of what may be styled artificial monoliths, the construction of the centres upon which the arch is to be formed, must always command serious attention on the part of the engineer. The principles upon which these centres are constructed, are much modified by local circumstances; for according to the facilities these may present for establishing intermediate points of support, it may be necessary to adopt particular descriptions of framing. The essential conditions of a centre may, however, be very briefly stated; they being in fact simply, that they should not be susceptible of deformation under the influence of the partial loads they will have to support, and that they should rigorously conform to the projected outline of the intrados; they must also be susceptible of being removed, after the completion of the work, without disturbing the arch itself. The centres are usually composed of timber framing, or trusses; either bearing upon the extremities of the opening, or upon intermediate points of support. Until within a few years the frames were made to rest upon wedges, and when the vaults were completed, these wedges were loosened by being driven back with hammers; but in the construction of some of the modern railway bridges of France, a system of placing bags filled with dry sand under the points of support, has been introduced with success. This ingenious system obviates the danger of jarring the fresh masonry in driving back the wedges, and it has the advantage of enabling the workmen to stop the descent of the centres at any time they may think proper. A description of it will be found in 'Les Annales des Ponts et Chaussées,' for November, 1849.

Whatever be the form, or the mode of bearing adopted, in executing the centres of a large bridge, it is necessary that it should be cross

braced, so as to hinder anything like lateral displacement of the trusses. It is equally important that the frames should not be allowed to rise under the action of the partial load; and, therefore, the crown of the centre must be tied down to the springing, and the crown itself must be weighted whilst the vault is being brought up symmetrically on the sides. As all wood framing is liable to some description of compression under the action of great loads, and as the materials of which every arch is composed are susceptible also of some degree of compression, it is customary to give an additional height to the centre beyond that which would rigorously be required if its outline were made to correspond exactly with the curve intended to be given to the intrados. There does not appear to be any rule for settling the height to be thus allowed; and evidently it must depend mainly upon the skill and attention of the workmen; but from the following table of the settlements of some arches, recorded by Claudel ('Formules à l'usage des Ingénieurs,' Paris, 1854), it will at once be seen that there is an absolute necessity for observing the precaution in question:—

Name.	System.	Span.	Settlement.
Nemours . .	Segmental.	53 ft. 2 in.	8 inches.
Nogent . .	Elliptical.	95 " 10 "	1 ft. 6 in.
Neuilly . .	"	128 " 0 "	2 " 2 "
Mantes . .	"	128 " 0 "	1 " 11 "
St. Sauveur . .	"	76 " 4 "	0 " 10½ "
Jéna . .	Segmental.	91 " 10 "	0 " 5 "

The principles which must be applied in the construction of centres have been ably discussed in Robison's 'Mechanical Philosophy' (vol. i. p. 661, ed. 1822), and it will be necessary to revert to the subject in the article on CARPENTRY. For the present, then, it will suffice to say that, in fact, the framing of a centre must be itself an arch able to support the weight of the vault; and that it is essential to convert all the strains upon the various parts of which it is composed, as far as possible into efforts of compression. Cross strains must be carefully avoided, and it is not even desirable to trust to the timber to any great extent, as furnishing ties to the rest of the framing.

Timber bridges have been used very frequently in countries wherein that particular material is abundant, and where neither the importance of the traffic nor the wealth of the country would justify the outlay required for the erection of a permanent structure of masonry. Thus in Switzerland, Germany, America, and in our own colonial possessions wooden bridges are commonly met with; but the very perishable nature of the material must always render its use objectionable in the great majority of cases. When, however, local considerations render it desirable to resort to the use of wood, the principles which should guide the engineer in designing the bridge must be substantially the same as he would adopt in designing any other piece of carpentry, but perhaps it is more essential that he should guard against the effects of atmospheric action upon the various parts of the framing he uses, than it would be necessary to do in ordinary cases. Thus it should be established as a rule that the piers and abutments of wooden bridges must be of masonry of impermeable materials; that no important part of the framing should be bedded in the masonry in such a manner as to prevent the free circulation of air around it; that no water should be allowed to lodge in the joints, or to remain in the bearings, of the framing; and that all the movements which naturally take place in the wood should be allowed to take place without interference from the mode of construction. The framing itself must be put together upon the ordinary mechanical principles adopted in carpentry; but it may be desirable here to state, that in the earlier bridges the timber was used simply as girders or straight horizontal beams; then Palladio and the Italian architects introduced a system of trussing with tie-beams; the German and Swiss engineers habitually resorted to trusses without tie-beams, and in which the thrust was carried down to the feet of masses of masonry by means of inclined struts, a system which has been applied with infinite modifications by the engineers of other nations; and latterly, the American engineers have resorted to the use of what may be called built beams, applied, in fact, as girders.

Of course the use of timber baulks as girders, can only be admitted when the openings are small, and the loads to be carried are not very great. In such cases the girders must be considered to be beams resting at each end on fixed supports, and loaded with a weight dependent upon the purposes the bridge is intended to fulfil. The resistance of a beam under such circumstances is directly proportional to its breadth multiplied by the square of its depth, and inversely proportional to the distance between the points of support. In most books upon construction are to be found tables of the multipliers to be used for ascertaining the transverse strength of the different kinds of wood, and in practice these tables are applied upon the supposition that the safe load should not exceed from $\frac{1}{4}$ to $\frac{1}{5}$ of the breaking weight ascertained thus:—

$$\frac{\text{tab. No.} \times \text{breadth} \times \text{depth}^2}{\text{length}} = x.$$

Timber.	Transverse Strength.	Crushing Force, per square inch in lbs.
Ash	2026	9023
Beech	1560	9048
Birch	1900	4567
Elm	1030	10331
Mahogany	..	8198
English oak	1800	..
African	2000	..
Red Pine	1340	5375
Teak	2460	12101

In calculating the strength of lateral trusses, reference must be had to the principle upon which they are designed, and the motives which may determine the choice of any particular system are so numerous that it would be dangerous here to lay down any abstract rules on the subject, further than to say that the simpler a truss is, and the fewer the number of its parts, the better will it be fitted for its work, both in so far as its resistance to the efforts it is intended to support, or its susceptibility of repair, are concerned. The object aimed at in designing a truss is to form artificially a rigid beam, through which the weight is ultimately resolved into a vertical pressure upon the points of support; and the parts of the truss must be so put together as to allow the various efforts of compression and tension to balance one another in a permanently safe manner. Some of the timber bridges upon the Utica and Syracuse railway afforded excellent illustrations of the mode of putting together trusses of this description, and the reader is referred to Weale's work on 'Bridges,' 8vo, London, 1843, for an account, and illustrations of them; but the lattice, or Thorn's bridges, and the Long's bridges, as they are called in America, are the boldest specimens of this mode of spanning large openings yet attempted. The formula adopted by the French engineers for calculating the resistance of the former bridges may here be quoted, as this mode of construction has found so little favour in the eyes of our own engineers that no work upon the subject can be referred to. It is to M. Garella (in 'les Annales des Ponts et Chaussées,' for 1842) that we are indebted for the formula in question, which is (in mètres)—

$$2P = \frac{Rc(b'^2 - b''^2)}{3b'a}$$

and in it $2P$ = the safety load; R = a co-efficient of the strength of timber; c = the united thicknesses of the whaling pieces; b' = the height of the truss; b'' = the distance, vertically, between the whales; and a = the half span. The formulæ for calculating the strength of ordinary trusses are reserved for the articles CARPENTRY and TRUSS.

Amongst the timber bridges in which the load is supported by a framing under the line of the roadway, by means of which framing the load is thrown upon the abutments without the intervention of any tie-beam, the most remarkable are perhaps the bent timber bridges erected upon the system first introduced into England by Messrs. Green, of Newcastle. In these bridges the principal portion of the weight is thrown upon an arched rib, formed of thin planks, bent flat, and fastened to one another with treenails, thus producing a beam of great strength and elasticity; but the very elasticity of the beams is an element of their destruction, for on every occasion of their changing their form, the various parts of which they are composed become more or less opened, and thus allow moisture to penetrate to their interior. It has thence happened that, in railway bridges especially, where the movements are unusually great, the arched ribs of thin planks, and also, it may be added, of square timber, rapidly decay. In a treatise by Colonel Emy, 'Sur la Charpenterie,' Paris, 1837; and in a brochure by Colonel Ardant, 'Sur les Charpentes à grand Portée,' Paris, 1840; the various conditions affecting arched timber beams are elaborately discussed; and in Krafft's work 'l'Art de la Charpente,' Paris, 1805, will be found a full description of the German and Swiss bridges, constructed upon the various systems hitherto adopted, when it has been impossible to introduce tie-beams.

Metallic bridges, which are not built upon the suspension principle, are either of cast or of wrought iron, or of a combination of iron and wood work. As cast iron is better adapted to resist efforts of compression than efforts of tension, it is preferable to use it only in positions where it is exposed to the former kind of action, and therefore it is that habitually cast-iron bridges are of the form of arcs of circles, and composed of a number of voussoirs. With spans inferior to 24 or 30 feet, however, straight cast-iron girders are often used to carry the roadway of bridges; their dimensions of course being ascertained by the rules commonly adopted in calculating those for ordinary cast-iron beams. Mr. Eaton Hodgkinson has given some empirical rules upon this subject, which may be briefly stated to be, that the area of the bottom flange should be as nearly as possible six times that of the top one; and that the breaking weight in the centre (of a girder uniformly loaded and supported at both ends) may be ascertained as follows: Calling the sum of the area of the bottom flange multiplied by the depth of the beam a ; the length of the bearing between the

points of support, b ; both of which are expressed in inches; then $x = \frac{ab}{1028}$; the safe load for a railway bridge, however, is only $\frac{1}{3}$ th of

the breaking weight thus ascertained. Mr. Beardmore states that the above formula may be applied to ordinary wrought-iron beams by making the co-efficient 1500 instead of 1028.

When the opening of a bridge exceeds the dimension above quoted, it is necessary to resort to a cast-iron arched beam; or to one or other of the descriptions of wrought-iron girders lately introduced upon the lines of railway, which have modified the arts of construction in this country, perhaps quite as much as they have altered the relations of society. Wherever there is a sufficient clear space under the bridge to allow the traffic to be carried on uninterruptedly, it is preferable, within certain very wide limits of span, to use cast-iron arches; and the very remarkable bridges of Southwark, Newcastle High Level, Laira, Nevers, Tarrascon, &c., may be referred to as illustrating the principles and the practical details of such works. In these cases, all the action upon the cast-iron arches resolves itself into one of compression, which is precisely the most favourable condition for the use of this metal; but as it is essential in a cast-iron bridge to keep the springing of the arch above the water-line, it very frequently happens that it is impossible to keep the whole of it below the line of roadway, or the line of the application of the live weight. In such cases it is necessary either to suspend the roadway from a cast-iron arch rising above the roadway itself, which will render inevitable the introduction of a horizontal tie; or to resort to the use of framed beams, lattice, or tubular girders. The bridge over the Regent's Canal of the North-Western Railway is a good illustration of the former system; the Newark Dyke, the Boyne and the Britannia bridges, are respectively illustrations of the three systems of wrought-iron bridges above-mentioned. It would be preferable to describe the principles which are considered to apply to these various systems under the head of girders *triangular*, *lattice*, and *box*; or the reader may refer for an investigation of their conditions, to the works of Messrs. Edwin Clarke, Fairbairn, Hodgkinson, Tate, Latham, Humber, Moseley, &c., wherein their respective merits are fully and elaborately examined. And it may suffice here to say that, up to an opening of 150 feet, any of those three systems may be adopted in bridges having the supporting beams above the roadway, according to local considerations of economy; above 150 and under 300 feet span, the choice is limited to the lattice and plate-iron tubular bridges; whilst above 300 feet span the tubular bridges only are admissible. When the latter extraordinary dimensions are attained, the stability of the structure can only be ensured by the use of deep tubes, consisting of an upper and a lower boom, calculated to resist the respective efforts of extension and of compression to which all girders are exposed; and either of close-plated sides, as in the Britannia, or of open framework, as in the Saltash bridge. In the former of these colossal structures, both the upper and the lower booms were composed of a series of rectangular cells; whereas in the Saltash Bridge the upper boom was composed of a large elliptical tube connected with the tie girders by means of a series of suspension rods. It is asserted that by this arrangement a considerable economy is produced in the iron-work of the bridge.

A very efficient system of trussing, known under the name of the Bowstring girder, has been applied in some of the modern railway bridges which do not exceed 120 feet span. The principle upon which it is based consists, as its name implies, in a curved boom, with a tension-chain at the feet, solidly attached to the boom by a lateral framing; the roadway is carried in these bridges directly upon the tie-chains, so that the other parts of the framing act as parapets. A very good example of this description of bridge is to be seen upon the Bow branch of the Blackwall Railway. The advantage of this system consists in its admitting of the nearest practical approach, in the outline of the girder, to the form of a solid of the greatest resistance with the least amount of material, and in thus diminishing the permanent load of the whole structure.

Until the recent introduction of the plate-iron girders, the only mode by which a roadway could have been carried across a very wide span, when it was impossible to construct a cast-iron arch beneath, either on account of the deficient headway, or on account of the difficulties in the way of fixing centres, was by the application of the system of chain or suspension bridges, first applied on a large scale by Telford upon the Holyhead road, the scene of the greatest achievements of modern engineering. In suspension-bridges, the roadway is suspended by vertical rods to chains of flat iron links, or to iron-wire ropes, which hang from cradles or saddles carried by masonry or iron piers, and are continued on the opposite side to what are called the anchoring-wells. The chains in such cases have permanently to support an effort compounded of, 1, their own weight; 2, of the weight of the suspension-rods, which varies with the lengths of the latter; and 3, of the weight of the roadway, which may be considered to be uniform in the length of the span. But in addition to this permanent effort, it is necessary to take into account the rolling load, the action of wind upon the whole structure, and, as in the case of all iron bridges, by the way, the effect of variations in the temperature upon the various parts of the work. Local circumstances, also, may render it necessary to modify the general system of suspension-bridges; for at times it may be desirable to dispense with the piers and back chains, whilst in others

it may be necessary to introduce a series of spans. In the latter cases, the chains may either be attached to the respective piers, or they may be carried over a series of saddles; and, in fact, there are so many reasons for modifying the details of these bridges, that they can only with difficulty be brought under any general rules.

According to Navier (whose work, 'Mémoire sur les Ponts Suspendus,' Paris, 1830, is still the text-book upon this subject), the formulæ which may be considered to represent the maximum tension in the direction of the arcs, and the horizontal tension at the top of

the piers are $T = \frac{P}{4} \sqrt{\frac{d^2}{f^2} + 1}$; and $Q = \frac{Pd}{8f}$; in which P is the total maximum load upon the arc; d , the span; and f , the versed sine. From these formulæ it appears, that the greater the versed sine the less strain is there upon the piers, or upon the chains themselves; but, at the same time, the length of the chain is necessarily increased, and the horizontal vibrations of the whole system are also rendered more dangerous, whilst the transverse vibrations are likewise increased. For these reasons, the ratio of the versed sine to the span of suspension-bridges is usually made to vary between the maximum of 1.7, to the minimum of 1.25; and in the Fribourg Bridge, the largest span hitherto attempted, the ratio is 1.14. The latter ratio is the one most commonly adopted. In all cases, and whatever be the material of the chains, the suspension-rods are placed at equal distances horizontally.

There is a remarkable difference in the theory and practice of English and of Continental engineers, with respect to the manner of resisting the vibrations to which the floors of suspension-bridges are exposed. English engineers, indeed, consider that the weight and rigidity of the whole structure are desirable conditions; whereas foreign engineers make the several parts as light and as elastic as possible. So many accidents have happened to suspension-bridges constructed on either of these principles, that it would be impossible to say which of them is the more correct; but it certainly would appear that when drawn iron suspension-rods are used instead of wire ones, it is very desirable to keep the roadway as stiff as it can be made, for if any undulations of great amplitude, such as have been described by Mr. Provis in his account of the Menai Bridge, should occur, the rods are very likely to break. Great stiffness may be given by trussing the hand-rail; by carrying the platform through the piers; and by introducing a system of cross-bracing under the roadways. These precautions, however, may be adopted upon either the English or the foreign systems above mentioned.

One of the most important parts of a suspension-bridge is the anchoring of the end of the chain, so as to interfere as little as possible with the contraction and expansion of its metal, and yet to resist the tension. Great precautions require to be taken, especially in the tying-down wells, to protect the chains from oxidation; and it may be interesting to add, that some of the worst accidents to suspension-bridges have arisen from the destruction of the sunk part of the back chains, precisely from this cause. This was the case with the bridge at Angers, which fell in consequence of the rusting of the wire-ropes in the wells; and so much are the said wire-ropes exposed to this particular danger, that it would appear to be desirable to exclude them entirely from that part of the work. In the open air, or in positions where they can be easily examined, however, iron-wire ropes present many advantages over the solid bar-iron chains or suspension-rods.

The wire-ropes used on the Continent consist, in fact, simply of annealed wires in close juxtaposition, bound round at intervals so as to prevent any longitudinal or lateral motion. They were originally introduced by M. Seguin, and described by him in a 'Mémoire sur les Ponts en Fil de Fer,' Paris, 1826; and have been successfully applied in an infinite number of cases, amongst others, in the Fribourg and the Niagara bridges: the latter is even used to carry a railway. A description of the Fribourg Bridge will be found in the 'Annales des Ponts et Chaussées' for 1835; a description of the great bridge, since fallen, of La Roche Bernard was published by M. Leblanc in 1841; and a description of the Niagara Bridge is to be found in Weale's 'Papers and Practical Illustrations of Public Works, 1856,' to which the reader is referred for details of the mode of forming the ropes, and of calculating their resistance. In the 'Annales des Ponts et Chaussées' for 1842 there is also to be found a description of an ingenious system of forming the cables and suspension-rods of hoop-iron instead of wire, which had been shortly before applied by Messrs. Flachet and Petiet in the construction of a bridge at Suresnes, near Paris; and there are to be found in the same valuable publication, especially of the period between 1832 and 1849, a series of interesting notices upon the various descriptions of suspension-bridges, and the accidents to which they are exposed. The latter have, unfortunately been very numerous of late years; and there certainly is at present, in consequence of these accidents, a tendency in the public estimation to undervalue this very useful and economical method of bridge-building. Even chain suspension-bridges have shared the disfavour of the iron-wire ones; and, in Paris especially, they have been pulled down with a most imperial disregard for expense; but certainly, if due precautions be observed, there can be no reason for the sudden revulsion in public opinion which has taken place with respect to suspension-bridges of all kinds; and the use of the woven-wire ropes especially would seem to obviate many of the objections which practically apply to the ordinary parallel stranded ropes used by the French engineers.

The "Dredge's Suspension-bridges," which were very favourably received in England a few years since, have been even more unfortunate than the other modifications of this style of bridge. They were principally remarkable for the attempted application in them of the theoretical principle that the strength, and consequently the weight, of the chain in any part of its length should diminish in proportion to the strain likely to be thrown upon it, and also for the peculiar inclined position of the suspension-rods. Such a system, however, is deficient in its powers of resistance to either horizontal or transverse waves, precisely at the point where their action is the greatest; and the consequence has been that, in the small bridges of the Regent's Park for instance, the platforms have been obliged in many cases to be supported by an intermediate framing.

It must be observed that, whatever be the description of chain employed in a suspension-bridge, the greatest danger to which that class of structures is exposed arises from regular impulses repeated at isochronous intervals. Occasionally the gusts of wind in storms occur thus; and the regular cadence of a body of troops passing over a suspension-bridge will also excite a vibration of a very dangerous character. In the case of the Pesth Bridge, however, the dimensions given to the various parts of the work have been sufficient to enable that structure to resist even the passage of troops in large bodies, in the hurry of a fierce fight.

The French government do not allow greater permanent weights than those quoted below to be applied to the respective materials named in the table; and they require that the dimensions of the various parts of the works should be calculated so as to present the sectional areas corresponding with the safety loads thus indicated.

Chain cables, safe load, per inch superficial	17,073 lbs.
Iron wire cables, safe load, per inch superficial	25,610 "
Vat hoop iron cables, safe load, per inch superficial	19,913 "

Rope bridges are so seldom used that it may suffice to refer to Sir Howard Douglas's work on Military Bridges for the details connected with them. Skew bridges, being only practical varieties of ordinary bridges, will be noticed under that head. [SKEW BRIDGE.]

Hitherto nothing has been said in this article about the mode of executing the foundations of bridges, for the reason that the same principles applying to those portions of all such buildings, it was considered desirable to notice first the modes of forming the superstructures, because they, in some cases, affected the details of the foundations intended to carry them. Now, the foundations of a bridge are required to resist two kinds of effort; namely, the vertical pressure of the load ultimately brought upon them, and the lateral thrust of the arches. Moreover, they must be executed in such a manner as to be able to resist any tendency on the part of external agencies to undermine the natural surfaces upon which they rest: this latter consideration applies with particular force to the foundations of bridges when erected in running water.

The powers of a foundation to resist the lateral displacement of the superstructure, depend, it may here be observed, upon the dead weight of that superstructure and the resistance of the bearing surface to motion, either through the adhesion of the material, or through the friction it may produce. This part of the investigation would be better treated under the head of FRICTION, and therefore the subsequent remarks refer only to the resistance of foundations to vertical loads.

The vertical pressure must of course be resisted by distributing the weight it represents over a base of practically incompressible materials. Of the natural soils there may be considered to be three great divisions, so far as regards their powers of resistance to efforts of compression; and they respectively require to be treated according to their powers of resistance. The first of these divisions is composed of the hard rocks, which can only be worked by the pick or by the use of gunpowder. The second is composed of sands, gravels, loams, clays, and other such easily worked materials, but which are practically incompressible when prevented from spreading laterally. The third is composed of the light earthy soils, of peat, mud, or other substances which are almost of a semi-fluid nature; and it is precisely with the latter that the greatest difficulties are encountered, at the same time that they are the most frequently to be met with in the beds and banks of rivers. As the differences between the various classes of foundations are so distinctly marked, and are so important in their practical bearings, the greatest care must be exercised in ascertaining the conditions actually prevailing in any case under investigation; and as it may at times happen that the top or upper bed of any particular situation may rest upon a softer and highly compressible substratum, it is essential that the observations upon the foundations of an intended bridge should be carried down to a very considerable depth, by means of shafts, wells, or borings. It may also happen that the natural stratum of any particular place may be able to resist the decomposing action of the air so long as the stratum itself is undisturbed; but that directly the outer surfaces are removed, as will often be the case when excavations are made for the purpose of receiving new foundations, the inner portions of the stratum will begin to decay. In fact, very careful examinations must be made of the geological nature and the mechanical structure of the materials about to be built upon, and the load brought upon them must be proportioned to their least powers of resistance. The boring tools must in such cases be skilfully and liberally applied, in order to

ascertain the real character of the formations upon which any great structure is about to be erected; for the indications obtained by means of trial piles are very likely to prove deceptive, because the resistance to their descent may frequently be so great in an upper stratum lying upon a soft under stratum, as to lead to very false conclusions on the subject of the ultimate resistance to a vertical load.

If the natural foundations should however have been studied carefully, in the manner above recommended, they must be treated according to their peculiar characters, as follows: The rocks and other resisting strata must be carefully levelled, without destroying the asperities on their surfaces which might be likely to increase the friction upon the bed. Any great inequalities of surface may be overcome by the application of a bed of concrete; but whenever this material is used, it must be composed of the best description of hydraulic lime or cement, and prepared with great care, so as to avoid anything like unequal settlements. When the natural foundations are composed of the sands, loams, and such heterogeneous materials, it becomes necessary to adopt precautions for the purpose of preventing any tendency to undermining; and with this intention, the position about to be covered must be surrounded with an inclosure of wood or iron piling; and, in rapid rivers especially, the level of the new foundations must be carried down so far as to obviate any danger of their being laid bare, by the removal of the subsoil, by the waters likely to find their way under them. The load must be distributed evenly over surfaces of this description, either by means of a timber platform, a coating of concrete, or a bed of large stones.

When the natural foundations consist of compressible strata, such as peat, soft mud, or other analogous alluvial deposits, of a considerable thickness, it becomes necessary to resort to the use of piles of wood or of iron; and when, as in the majority of the river-beds of India, there is a great depth of running sand, it may become necessary even to sink wells, which are subsequently to be filled in with concrete. When wooden piles are used, care must be observed in the selection of the kind of wood employed; for beech, the material most usually adopted on the Continent, decays rapidly when exposed to alternations of wetness and dryness; elm resists more satisfactorily in situations so exposed; whilst oak and fir, especially if free from sap in the commencement, will last longer than either of the above woods. There is another danger to which wood piles are exposed,—namely, the attacks of the boring worm; and as it appears that the process of creosoting renders wood so distasteful to those creatures that they will not touch it when so prepared, it would seem to be essential to subject all piles to that process. It is said that the boring insects exercise their ravages more particularly upon piles driven into the strata able to furnish them with the carbonate of lime requisite for their growth; but, unfortunately, they are nearly as destructive to piles driven into silicious sands, and the only places which seem to enjoy immunity from their attacks are those situated near the outlets of sewers or drains containing much sulphuretted hydrogen.

Piles are called, according to the positions they occupy in a foundation,—1, *Gauge piles*, or those driven for the purpose of defining the limits of the ground, or of guiding the position of the rest of the work; 2, *Sheet or close piles*, which form a continuous inclosure, the term close piles being used when whole baulks are employed, and sheet piles when timber of smaller scantling is employed. These various descriptions of piles are united by *whales*, or horizontal ties, by cross braces, and occasionally by struts. Their entry into the ground is facilitated by cutting the ends into a pyramidal form, and by fastening either cast or wrought iron *shoes* upon the point; the heads of the piles are *hooped* with wrought iron, in order to prevent their being split in driving. Occasionally however piles are driven with a broad flat end, as in foundations upon a great thickness of compressible mud; and Peyronnet considered that this system was advantageous when the middle of the piles was situated at nearly the mean level of the water. It is important, when piles are thus driven with the small end downwards, to begin by the outer ones, and then proceed inwards.

The weight to be brought upon the top of a pile is usually calculated upon the supposition that it would derive no support from the ground into which it is driven; and Rondelet has given a series of tables in which he states the safe load to be placed on piles of certain heights and scantlings, calculated upon the principle of their being able to support those loads in the open air. It may briefly be stated that, provided the height of the pile should not exceed 16 times the scantling (or diameter), it may safely be loaded with from 430 to 500 lbs. per superficial inch of the sectional area.

When the piles are driven into soft ground of considerable depth, it is customary to leave off driving when a certain resistance to their progress is attained. This resistance is made proportionate to the weight of the ram, and to the height through which it falls; but it must be observed, that there is danger in the use of any description of machinery by which frequent heavy blows are struck upon the pile-heads; for in such cases, their heads may either be set on fire, or knocked up into a spongy mass, or the piles may be split. Moreover, as there is a tendency, when frequent heavy blows are struck upon the piles, to produce a state of vibration in the ground around them, which may seriously interfere with their descent, it would appear to be preferable to employ for pile-driving only such machinery as is capable of striking heavy blows at tolerably distant intervals. Of course, however, this rule

must be considered to be exposed to many exceptions, and great judgment will be required in the choice of the mode of pile-driving to be employed in any particular case. The very valuable machinery introduced by Mr. Nasmyth has, for instance, failed as signally in some cases as it has succeeded in others.

Some very ingenious systems of sinking what may be termed hollow cylindrical piles of large diameter (which are subsequently filled in with concrete in the same manner as the brick wells before alluded to, as being used in India), have lately been introduced in England. The first serious attempt of this nature was made by Dr. Potts, who caused the cylinders to descend by pneumatic pressure, and upon this system founded very successfully some of the bridges on the Richmond, and the Chester and Holyhead lines of railway. Great improvements upon this system have been made by Mr. Hughes, who directed the works of the Rochester bridge, under Sir William Cubitt; and more recently still, the continental engineers have applied upon a great scale the method of sinking cylinders by the use of pneumatic machinery. A description of the methods respectively adopted may be found in a small brochure published by Mr. Hughes; and in vol. xvi. of the 'Annales des Travaux publics de la Belgique,' for 1857-58.

The observations above made with respect to pile-driving were made upon the supposition that the piles were to be placed in such positions as to allow of their being driven in the open air; but if they should be entirely under the water-line of the river to be built in, it may be necessary to construct a coffer-dam, or a temporary enclosure, for the purpose of pumping out the water, and allowing the workmen to operate freely in the dry. The principles upon which coffer-dams are formed, are discussed under that head [COFFER-DAM]; but it is necessary here to remark, that their use is not now considered to be so indispensable as it was formerly. When the extreme limit of the scour to which a river's bed is exposed has been ascertained, and a solid substratum is known to exist below that limit, it is found to be sufficient, especially in the cases of bridges of large span, to surround the intended positions of the piers by an enclosure of close piling, and then to dredge out the alluvial matter, or silt, upon the top of the resisting substratum, and to fill in the space thus cleared with good hydraulic concrete, nearly up to the water-line. Nearly all the large bridges lately erected upon the continent have been founded in this manner; and though the majority of the older members of the engineering profession in England still adhere to the more expensive system of coffer-dam foundations, there appears to be no substantial reason for the non-adoption of the continental system in our own country. In fact, it has been applied by Messrs. Vignolles, Page, &c., hitherto with success. The important conditions to be aimed at in forming such foundations are, firstly, that they should be protected from any possible danger of undermining; and then, that the concrete filled in between the sheet piling should set rapidly, and permanently. So much indeed depends upon the composition of the concrete used in all descriptions of foundations, that it is advisable to devote a separate article to its consideration. [CONCRETE.]

In the old Westminster Bridge, Labeleye introduced a system of foundations, which perhaps may still be safely applied in some positions, but which has proved to be signally unfit for the beds of rivers exposed to great scouring actions. He used, in this, large caissons, or boxes, of the extreme size of the intended piers; and he caused them to be sunk upon a bed supposed to have been prepared by dredging, to receive them: the masonry of the piers was then continued upon the floor thus formed. Unfortunately the natural bed of the Thames at the place where Labeleye tried his experiment was of a very variable character, and the unequal resistances it has offered to the weights brought upon the caissons have allowed the piers and arches to move in so dangerous a manner that the bridge must be pulled down within about a century from its construction. De Cessart applied the same system to some of the bridges over the Loire; and Smeaton continued its use in our own country, in the foundations of Ramsgate pier, for instance; but at the present day, engineers have almost unanimously condemned a mode of construction known to be exposed to very serious and irreparable accidents.

Floating, turning, lifting, and pontoon bridges being merely local modifications of this class of constructions, are briefly noticed under their respective heads.

We add a table of the form, material, and size of the principal bridges, aqueducts, and viaducts, of which the construction and proportions have been obtained:—

The column marked 1, indicates the total length between abutments; 2, the No. of arches; 3, the form of arch; 4, the chord of principal span; and 5, the ver. sin. of principal span.

The capital letters in the first column indicate the material:—B. brick; I. iron; W.I. wrought iron; C.I. cast iron; M. marble; S. stone; T. timber.

BRIDGE HEAD, or *Tête de Pont*, is a fortification covering that extremity of a bridge which is nearest to the position occupied by the enemy, in order, by securing the line of communication, to facilitate the advance of an army or protect its retreat.

When a bridge is built across a river which runs through or along one side of a fortified town, the ramparts of the town in the one case, and those constructed for the defence of any buildings beyond the river in the other, may be considered as constituting the bridge-head; and then the works enter into the class of permanent fortifications. In other circumstances their form depends upon the nature of the ground, and upon the importance of the pass to be secured. If a retreating army is likely to be exposed to a serious attack when about to cross a river, the works must be strong enough to keep the enemy in check, and sufficiently extensive to contain the whole army, till the passage can be effected.

The simplest kind of bridge-head is one which has the form of a *redan*; that is, a breast-work, with two branches disposed on the plan like the sides of the letter A, and terminating on the bank of the river. But when a more perfect defence is required, the bridge-head may have the figure of a horn-work, or of a bastioned front; the area to be occupied by the defenders being inclosed, except at the gorge or river side, by the rampart or breast-work. When, however, the bridge-head is to be sufficiently capacious to serve as an intrenchment for the whole of an army, it may consist of a series of redoubts or redans flanking each other reciprocally, and disposed on a curve line whose extremities rest on the river; and whatever be the nature of the work, when its capacity is considerable, it is always advisable to have a redan or small fort immediately covering the bridge, acting as an interior retrenchment, with its faces so disposed that their fire may defend the intervals between, and flank the exterior redoubts. This retrenchment serves, after the main body of the army has passed over the river, for a small division acting as a rear-guard, to protect the retreat of the troops employed in defending the principal works. The passages by which an army or detachment, in retreating, enters a bridge-head consisting of a continuous parapet, should be situated in the re-entering angles of the work, if such there be, where they may be well flanked by crossing fires from the collateral faces; and they should be defended by a direct fire from traverses in the interior.

To prevent the enemy from advancing towards a bridge along the bank on which the works are situated, that bank, both on the right and left of the bridge, should be well defended by a fire of musketry or artillery; consequently the parapets adjacent to the river should be as near as possible perpendicular to its direction. And it is evident that the most favourable situation for a military bridge is at a bend of the river where the concavity is towards the enemy's position, for the fortifications will thus conceal the bridge from his view; and on either side of the work the brisures intended to defend the ground immediately in front may be directed towards the river, by which they will be secure from an enfilading fire of the enemy.

Should any commanding ground permit the enemy to direct a plunging fire of artillery upon the bridge or within the works, and

should it be found impossible to give to the parapets a height sufficiently great to intercept that fire, batteries or redoubts must be constructed in convenient situations on the rear side of the river, in order by their fire to prevent the enemy from occupying that ground. Those works will also serve to defend the faces of the bridge-head when attacked; a traverse also should be raised on the same side of the river, perpendicularly to the length of the bridge, in order to enfilade the latter in the event of the enemy attempting to force a passage over it before it can be destroyed.

When there are islands in the river, it is advisable to establish the bridges so that they may connect the islands with the opposite banks, for thus the bridges, being shorter than if they were to extend quite across the river, may be more numerous, consequently the passage of the river will be facilitated and more effectually defended. There should be a separate bridge-head for each bridge, besides the general bridge-head on the farther bank; and any collateral islands there may be should be fortified, both to prevent the enemy from occupying them, and thus obtaining a view of the bridge, and to afford the means of flanking the principal bridge-head.

The most important bridge-heads in Europe are on the Rhine, at Ehrenbreitstein, Mannheim, Kehl, and Huningen; all these have been celebrated in the wars of which the frontiers between France and Germany have so frequently been the theatre.

BRIDGE, MILITARY. Military bridges may be classed under the following heads: Pontoons; Boat; Rope; Boat and Rope; Cask; Trestle; Raft; Pile and Spar; Flying Pivot; Flying Trail.

Pontoon and cask bridges are described under **PONTOON**; flying pivot and flying trail bridges, which are in fact nothing more than ferries, under **FLYING BRIDGE**.

Boat bridges are formed by an army, when unprovided with pontoons, from any small craft which can be collected on the river to be crossed; and when a bridge of this kind has to be formed in presence of an enemy, feints should be made at various points of the river, to deceive him as to the real place where, by a rapid movement, all the accessible boats are collected. Decked boats, as used for cargo, are the most adapted for the purpose; and in order to make good the irregularities in the heights of the various kinds, trestles are placed along their centres to carry the superstructure, the baulks of which should never rest on the gunwales. The bridge constructed over the Indus by Capt. G. Thomson, H. E. I. C. Engineers, which is described at page 92, vol. iv. 'R. E. Corps' Papers,' is an excellent example of boat bridges, for which no particular size and construction can be given, as they vary so much with circumstances and the *matériel* procurable.

Rope bridges are principally applicable for spanning the broken arch of a bridge, or for crossing a narrow river with steep banks. That constructed by Col. Sturgeon over the broken arch at Alcantara (in 1810), which spanned 100 feet, is an example both of method of construction and applicability of this material, where, as in this case, timber cannot be procured, or great portability is desired. Boat and rope bridges are often of great use. The bridge over the Adour, designed by Col. Sturgeon and executed by the Royal Engineers, is perhaps the best example ever constructed. The method of stretching the rope-work was much the same as that used at Alcantara, and will be found described in Sir H. Douglas's work on military bridges. The boats used were 48 *chasse-marées*, which were anchored stem and stern, to meet the run of the tide both ways, at first with one, but afterwards with two anchors, on account of the violence of the current. Trestle bridges are chiefly applicable to streams in mountainous countries, liable to sudden rises, and therefore often unfordable; and where the previously mentioned means are not procurable. The trestles are made of any rough timber, sufficiently high to carry the superstructure above any probable rising of the water, and are kept firm by being loaded with stones at the bottom, and by strong ropes or cables passed across and fastened to the tops. Sir H. Douglas mentions a trestle bridge constructed across the Agueda by Col. Sturgeon, which was 396 feet long, and carried on eighteen trestles.

Raft bridges are ill adapted to an army, as they are very unmanageable, especially when the passage is contested, and besides having little buoyancy, become waterlogged when kept long in the water. They have the advantage, however, where timber is plentiful along the bank of a river, of being made on the spot and requiring few skilled workmen, a few cables being the only *matériel* brought from the rear.

Pile and spar bridges are a more permanent description of bridge, though occasionally, when the stream is wide and deep, and the bottom suitable for pile-driving, they may be of great service to the military engineer.

For further particulars on this most important subject in military science, the student is referred to Sir Howard Douglas on Military Bridges, and the R. E. 'Aide Mémoire,' from which the above has principally been taken.

BRIDGES are of two classes, public and private. Public bridges may be considered either as county bridges or as highways, although the principle of that distinction does not seem very clear. Every county bridge is a highway, inasmuch as it is a bridge over which a highway passes; it is therefore in that respect strictly a highway: so also is every other public bridge over which a highway passes. The usual distinction drawn between them is derived from the nature of

the space over which the bridge gives a passage. A county bridge, or, in other words, a bridge which the county is bound to repair, is usually defined to be "a common and public building over a river or water flowing in a channel more or less definite; whether such river or channel is occasionally dry or not." This is evidently a very loose definition, for it does not prescribe the width of the river or the nature of its channel; but it seems clear that a county bridge must pass over a water, as the county would certainly not be bound to repair a bridge erected across a ravine, or over an ancient road crossed by a new road, having no reference to water. A county bridge may be either a foot, horse, or carriage bridge. A private bridge is any bridge which does not answer the description of a county bridge or a public highway. It is subject to no other laws than the general laws of property.

The liability to repair a county bridge depends either on the common law or on the statute law. By the common law the expense of maintaining both county bridges and highways is to be defrayed by the public, this having been part of the *trinoda necessitas* to which every man's estate was formerly subject. [TRINODA NECESSITAS.] But the burden of repair of county bridges is thrown on the whole county, that of highways on the inhabitants of the parish wherein such highways lie. *Prima facie*, therefore, by the common law the whole county is liable to repair a county bridge; but they may rebut this presumptive liability by showing that for some reason or other the burden has been shifted from them on another. They may either show that a hundred, or a parish, or some other known portion of a county is by custom chargeable with the repair of a bridge erected within it; or that some person, individual or corporate, is liable to that expense. In the case of private individuals, such liability may depend either on tenure, that is, by reason that they and those whose estates they have in the lands or tenements are liable in respect thereof;—or on prescription. In the case of corporate bodies, on prescription only. With regard to corporate bodies, Lord Coke says, "If a bishop or prior, &c. hath at once or twice of almes repaired a bridge it bindeth not (and yet is evidence against him, until he prove the contrary); but if time out of mind they and their predecessors have repaired it of almes, this shall bind them to it." (2 'Inst.' 700.) Any bridge answering the definition above given of a county bridge may become a charge upon the county even though not originally built by the county; as, for instance, if it be built by the crown or a private individual: but not every bridge which answers the above definition is therefore chargeable to the county for repair, unless it be also used by and useful to the public. The public use and benefit seem to be the criterion: and if a private individual build a bridge of any sort, which is principally for his own benefit and only collaterally of benefit to others, he will be liable to the repair, and not the public: but where the public derive the principal benefit, they must sustain the burden of repairing it, on the ground that it would greatly discourage public-spirited persons from erecting useful bridges if they were ever after to be burdened with the costs of repair. The county are even liable to the repair of a public bridge erected by commissioners under an act of parliament, even though the commissioners are empowered to raise tolls in order to support it, or though other funds are provided for the repairs; unless there be a special provision for exonerating them from the common law liability, or transferring it to others. This common law liability of a county to repair a public bridge is so strong, that although it has been erected and constantly repaired by trustees under an act of parliament, and although there are funds for the repairs, the county are still liable to it. And where trustees under a turnpike act build a bridge across a stream, where a culvert would have been sufficient, but a bridge was better for the public, it was held that the county could not refuse to repair such bridge on the ground that it was not absolutely necessary.

The first statute on this subject is the 22 Henry VIII. c. 5, called 'the Statute of Bridges.' This statute is merely in affirmance of the common law. In course of time, owing to the indistinctness of the principle on which public bridges were divided into county bridges and highways, it was found expedient to pass an act to clear up the doubts and difficulties arising from this principle. In order, therefore, to ascertain more clearly the description of bridges hereafter to be erected, which inhabitants of counties shall and may be bound or liable to repair and maintain, it is enacted by stat. 43 Geo. III. c. 59, s. 5, that no bridge hereafter to be erected in any county at the expense of any individual or private person, body politic or corporate, shall be deemed to be a county bridge, unless it shall be erected in a substantial and commodious manner under the direction or to the satisfaction of the county surveyor, or person appointed by the justices of the peace at quarter-sessions to superintend and inspect the work. This act applies only to bridges newly built, and not to those repaired or widened.

It was found in very early times that many practical difficulties arose from the indistinctness of the common law as to the precise limits of a bridge—that is to say, as to the precise point where it ceased to be a bridge and began to be a highway; and vice versa. This indistinctness gave rise to many disputes about the liability to repair, and it was found expedient to enact, by stat. 22 Henry VIII. c. 5, § 9, that such part and portion of the highways as lie next adjoining to the ends of any bridges within this realm, distant from any of the said ends by the space of 300 feet, be made, repaired, and amended as often

as need shall require; and that the justices of the peace should act respecting the repairs of such highways as they were empowered to act respecting the bridges themselves. The effect of this statute was merely to limit or fix the length of road which the county was to repair at 300 feet. By the common law the county was bound to repair the roadway at the end of every county bridge, but the length was not precisely determined till the passing of the above statute.

But this liability of the county has been very much narrowed by the stat. 5 & 6 Will. IV. c. 50, § 21 (the General Highway Act), which, with respect to bridges to be built after the 20th of March, 1836, enacts, "that if any bridge shall hereafter be built, which bridge shall be liable by law to be repaired by and at the expense of any county, or part of any county, then and in such case all highways leading to, passing over, and next adjoining to such bridge shall be from time to time repaired by the parish, person, or body politic or corporate, or trustees of a turnpike road, who were by law, before the erection of the said bridge, bound to repair the said highways: provided, nevertheless, that nothing herein contained shall extend to exonerate any county or part of any county from repairing the walls, banks or fences of the raised causeways and raised approaches to any such bridge or the land arches thereto."

Till late years no persons could be compelled to build or to contribute to the building of any new bridge, except by act of parliament; and even when the county was bound to repair a bridge, it was not therefore bound to widen it. Nor could the inhabitants of a county by their own authority change the situation of a bridge. But by the stats. 14 Geo. II. c. 33, § 1, and 43 Geo. III. c. 59, § 2, the justices in quarter-sessions are enabled to compel the county to widen or change the situation of old bridges, or build new ones. (See also 54 Geo. III. c. 90, which extends some of the provisions of those statutes.)

The 13 and 14 Vict. c. 64, provides that certain bridges which have been included within the boundaries of cities or boroughs, shall be repaired and maintained under the sole control of the council of such cities or boroughs.

The Railway Clauses Consolidation Act, 1845 (8 & 9 Vict. c. 20), contains various provisions as to the erection and maintenance of bridges over and under railways.

With respect to the appointment of surveyors of county bridges, their duties and powers, and the modes in which such powers are to be exercised, see stats. 22 Hen. VIII. c. 5, § 4; 43 Geo. III. c. 59 (coupled with stat. 5 & 6 Will. IV. c. 50); 54 Geo. III. c. 90; 55 Geo. III. c. 143. The provisions of these statutes are very numerous.

For the mode of taxing and collecting the moneys necessary for the repairs of bridges and the highways at the ends thereof, see stat. 22 Hen. VIII. c. 5; Anne 1, stat. 1, c. 18; 12 Geo. II. c. 20; 52 Geo. III. c. 110; 55 Geo. III. c. 143.

By the 4 & 5 Vict. c. 49, the justices at quarter-sessions may borrow money for repairing county bridges on the credit of the county rate.

In case of non-repair or nuisances, either to bridges or highways, the modes of prosecution are the same: namely, by criminal information, presentment, or indictment. Generally speaking, an action cannot be maintained against the county by an individual for the non-repair of a county bridge, unless in some cases of special damage accruing to such individual from the non-repair.

A criminal information is very rarely resorted to, and only in cases of either very aggravated neglect or where there seems to be little chance of obtaining justice by preferring an indictment.

The presentment of a public bridge for non-repairs, &c. may by common law be before the Queen's Bench or at the Assizes. By the stat. 22 Hen. VIII. c. 5, § 1, presentments may be made before the justices in general sessions, and they may proceed therein in the same manner as the judges of the Queen's Bench were in the habit of doing, "or as it should seem by their directions to be necessary and convenient for the speedy amendment of such bridges." See also for minor regulations respecting presentments, 1 Anne, sess. 1, c. 18; 12 Geo. II. c. 29, § 13; 55 Geo. III. c. 143, § 5.

The indictment of a county bridge is subject to the same rules as any other indictment. And though the whole county be liable to the repairs, any particular inhabitant of a county, or tenant of land charged to the repairs of a bridge, may be made defendant to an indictment for not repairing it, and be liable to pay the whole fine assessed by the court for the default of repairs, and shall be put to his remedy at law for a contribution from those who are bound to pay proportionable share in the charge.

The malicious destruction or damaging of public bridges is said to be punishable as a misdemeanour at common law, since it is a nuisance to all the king's subjects. By 7 & 8 Geo. IV. c. 30, § 13, it is enacted, "that if any person shall unlawfully and maliciously pull down or in any wise destroy any public bridge, or do any injury with intent and so as thereby to render such bridge, or any part thereof, dangerous or impassable, every such offender shall be guilty of felony."

(For further information see Lord Coke's *Second Inst.*; Burn's *Justice*; Russell *On Crimes*. For the law of bridges, viewed as highways, see WAYS.)

BRIEF (in law), an abridged relation of the facts of a litigated case with a reference to the points of law or evidence supposed to be applicable to them, drawn up for the instruction of the advocate who is to conduct the proceedings in court. Briefs vary in their particular

qualities according to the nature of the court in which the proceedings are pending, and of the occasion in which the services of the advocate are required; but in general they contain the names and descriptions of the parties, the nature and precise stage of the suit, the facts of the litigated transaction, the points of law intended to be raised, the pleadings, the proofs, and a notice of the case which may be raised on the other side.

BRIEF, commonly called **CHURCH BRIEF** or **QUEEN'S LETTER**. This instrument consisted of a kind of open letter in the royal name, and sealed with the privy seal, directed to the archbishops, bishops, clergymen, magistrates, churchwardens, and overseers of the poor throughout England. It recited that the crown thereby licensed the petitioners for the brief to collect money for the charitable purpose therein specified, and required the several persons to whom it was directed to assist in such collection. The origin of this custom is not altogether free from doubt; but as such documents do not appear to have been issued by the crown previously to the Reformation, they may possibly be derived from the papal briefs, which, from very early periods of the history of the Church, were given as credentials to mendicant friars, who collected money from country to country, and from town to town, for the building of churches and other pious uses. It is probable that, as soon as the authority of the pope ceased in England, these briefs began to be issued in the name of the sovereign. They appear to have been always subject to great abuse; and the stat. 4 Anne, c. 14, after reciting that "many inconveniences arose and frauds were committed in the common method of collecting charity money upon briefs," enacted a variety of provisions for their future regulation, and, among others, prohibited, by heavy penalties, the practice, which had previously prevailed, of farming briefs, or selling, upon a kind of speculation, the amount of charity money to be collected. Still these provisions were evaded, and heavy abuses arose; and the collection by briefs in modern times was found to be a most inconvenient and expensive mode of raising money for charitable purposes. ('Burns's Ecclesiastical Law,' tit. Brief.) The machinery provided by the statute of Anne was abolished by 9 Geo. IV., c. 42, which enacted "That, as often as his Majesty shall be pleased to issue his royal letters to the Archbishops of Canterbury and York respectively, authorising collection within their provinces for the purpose of aiding the enlarging, building, rebuilding, or repairing of churches and chapels in England and Wales, all contributions so collected shall be paid over to the treasurer of the 'Incorporated Society for promoting the enlargement, building, and repairing of churches and chapels,' and be employed in carrying the designs of the society into effect." This statute does not interfere with the authority of the crown as to granting briefs; Queen's letters have accordingly been issued till within the last few years; but they are now considered permanently abandoned.

BRIEF (PAPAL) is the name given to the letters which the pope addresses to individuals or religious communities upon matters of discipline. The Latin name is "brevis," or "breve," which in the latinity of the lower ages meant an epistle or written scroll. The French in the old times used to say "brief" for a letter, and the Germans have retained the word "brief" with the same meaning to this day. The difference between a Brief and a Bull in the language of the Papal Chancery is this: the briefs are less ample and solemn instruments than bulls, and are like private letters addressed to individuals, giving the papal decision upon particular matters, such as dispensations, release from vows, appointments to benefices in the gift of the see of Rome, indulgences, &c.; or they are mere friendly and congratulatory letters to princes and other persons high in office. The apostolical brief was formerly written on paper, but is now usually written on parchment; with the difference that the bull is written on the rough side in ancient characters, the brief is written on the smooth side in the modern characters; it is sealed in red wax with the seal of the Fisherman (*sub annulo Piscatoris*), which is a symbol of St. Peter in a boat casting his net into the sea. (Ciampini, 'Dissertatio de Abbreviatorum Munere,' cap. iii.) A bull is a solemn decree of the pope in his capacity of head of the Roman Catholic Church: it relates to matters of doctrine, and as such is addressed to all the members of that church for their general information and guidance. The bulls of excommunication launched by several popes against a king, or a whole state, are often recorded in history. The briefs are not signed by the pope, but by an officer of the Papal Chancery, called 'Segretario dei Brevi:' and they are indited without any preamble. The bulls are always on parchment, and sealed with a pendent seal of lead or green wax, representing on one side the heads of St. Peter and St. Paul, and on the reverse the name of the pope, and the year of his pontificate: their name comes from the Latin 'bulla,' a carved ornament or stamp. The bulls of indulgences are general, and addressed to all the members of the church; the briefs of indulgences are addressed to particular individuals, or monastic orders, for their particular benefit.

BRIEVE, a term once of much more frequent use in the law of Scotland than it is at the present day. It would appear that when the supreme civil court consisted of a committee of Parliament, permission to sue before that body was granted by brief from the Chapel Royal of Chancery, containing the questions on which a decision or answer was required. It is now a writ, served by authority of the crown, directing an inquiry to be made by means of a jury, into certain matters specified. Of the inquiries conducted by briefs, the most

important was, till lately, the brief for service of heirs. This form was necessary for establishing the title of an heir in his ancestor's landed property. The brief for this purpose was abolished by 10 & 11 Vic. c. 47. [HEIR.]

The briefs still known in the law of Scotland are:—the brief of Tutor, by which an inquiry is made as to the person legally entitled to be tutor (guardian) to a pupil (that is a child under 14 years of age if a male, 12 years if a female), the briefs of Idiocy and Furiosity, by which inquiry is made as to the question of a person's imbecility or insanity, before he is judicially deprived of the management of his affairs; the brief of Terce, for establishing the right of a widow to terce (dower); the brief of Division, dividing the lands of heirs portioners (coparceners).

BRIG, BRIGANTINE. [SHIP.]

BRIGADE. This term is generally applied, in military affairs, to the union of two or more battalions or regiments in one corps; but sometimes to the union of a certain number of men or guns in one subdivision. Thus from two to six battalions of infantry, or squadrons of cavalry, constitute a brigade. The British Rifle Brigade is composed of four battalions. The term brigade is also applied to a small party of Sappers consisting of eight men, which is divided into two demi-brigades of four men each, one demi-brigade only being employed in the execution of a trench by single sap. Six pieces of ordnance form a brigade of artillery. According to Père Daniel, commanders having the charge of several regiments, and the title of brigadiers, were instituted, in France, by Louis XIV. In the British service the commander of each brigade is entitled brigadier-general: his rank, which is only a temporary one while immediately in command, is immediately above that of colonel; and, to assist him in the performance of his duties, there is appointed a brigade-major, who is usually a captain, or if a subaltern, he holds in the brigade the rank of junior captain. An effective field-officer of a regiment is not eligible to this post.

The British army is not usually organised into brigades in time of peace except at the camps, but on active service the commanders of regiments make their reports to the brigadier-general; the latter transmits them to the general of the division, and through him they are communicated to the adjutant-general or to the commander-in-chief.

Not only the number of battalions which are united to form a brigade, but also the number of brigades which constitute a division, is various; both brigade and division depending upon the strength of the several regiments and upon the nature of the service. It may be sufficient to mention, that at the battle of Corunna, where the British army consisted of about 25,000 men under arms, the first line was formed of three divisions, the division constituting each wing consisted of three brigades, and the centre division of two; some of the brigades were composed of four battalions, some of two, and one of them of three. The infantry in the second line was, in like manner, unequally divided; the centre consisted of two brigades of cavalry, one formed of three regiments, and the other of two; and there were eleven brigades of artillery.

As the separation of an army into two or more principal divisions permits the greater changes of disposition in the line to be effected with a unity of design which is essential to their utility, so the secondary evolutions are accomplished with a corresponding advantage by the subdivision into brigades. The battalion being considered the unit of the modern tactical system, the brigade is the first multiple, the division the second, varying in numbers according to the exigencies of the service. The head of the army having communicated the general plan of the action to the officers who are immediately under him, relies on them for the execution of his plans, and is thus relieved from the necessity of following with his own eyes the movements of each particular battalion; while those officers, having the power of distinguishing themselves, either by a faithful adherence to the orders they may receive, or by the exercise of their judgment in modifying such orders according to the varying circumstances of warfare, are thereby prompted to display all their energies in making the necessary dispositions, and subsequently in animating the troops who are to execute them.

BRIGANTES, a tribe of ancient Britons who occupied that part of England which includes the counties of York, Lancaster, Cumberland, Westmoreland, and Durham, with the exception of the SE. corner of Yorkshire between the Humber and the sea as far as Flamborough Head, which was inhabited by the Parisii (Camden's 'Britannia'). The Brigantes first occur in Roman history under the reign of Claudius, when, having partially risen against the Romans during the war between the latter and the Iceni, they were defeated by the Prætor M. Ostorius, when some of their leaders were killed, and the rest submitted and obtained peace (Tacitus, 'Annal.' xii. 32.) During the civil wars of the empire, after Galba's death, the Brigantes revolted against their queen Cartismandua, who was an ally of the Romans, and who had forsaken her husband Venutius for a lover. Cartismandua escaped with great difficulty and by the assistance of some Roman cohorts, and Venutius remained master of the country of the Brigantes, and at war with Rome (Tacit. 'Hist.' iii. 45). Under Vespasianus the Brigantes were totally defeated by the Prætor Petilius Cerealis, after a severe struggle, and the Romans took possession of the greater part of

their country. Tacitus describes them as the most numerous tribe in the whole province of Britain ('Agricola,' xvii.) We find the Brigantes mentioned again under the reign of Antoninus Pius, when they made incursions into the neighbouring territory of Genunia (Pausan. viii. 43), which was subject to the Romans, for which they were attacked and defeated by Lollius Urbicus, and part of their territory was taken from them.

We find in Ptolemy a tribe of Brigantes in Southern Hibernia, between the rivers Birgus (Barrow) and Dabrona (Blackwater), occupying the space included in the modern counties of Waterford and Tipperary. They are supposed by some to have emigrated from Britain.

The Brigantes must not be confounded with the Brigantii, a tribe in Vindelicia, near the borders of the lake of Constance, whom Strabo (iv. p. 206, Causaub.) mentions as terrible robbers, whose name was the dread of the neighbouring countries, and who in their incursions into Italy used to commit the greatest cruelties, killing all the men and male children, and even the pregnant women. Whether it was from the traditional character of these Brigantii, or that the word itself meant in its original language marauders, or "free hands," as some have interpreted it, the name appears to have been held ever after in disrepute, and we find the French in the middle ages using the word Brigands as synonymous with armed adventurers. The English also used to say of a bold lawless fellow, "he plays the Brigands." (Camden.) In the wars of the French Revolution and of Napoleon, the appellation Brigands became common in the French invading armies to signify all those who resisted them without being regular soldiers, whom accordingly they did not consider as entitled to any of the courtesies of modern warfare.

BRIGHT'S DISEASE. [KIDNEYS, DISEASES OF.]

BRIMSTONE. The chemical relations of this important substance are treated under SULPHUR; but, as the Customs' authorities still employ the old-fashioned name of brimstone, we may briefly notice here the vast extent of the trade. In the three years 1856, 1857, 1858, the quantity of brimstone imported was as follows:—

1856		1,410,607 cwts.
1857		987,811 "
1858		1,156,476 "

averaging no less than 130 millions of pounds per annum. The chief employment is in the manufacture of gunpowder, ignitable matches, and sulphuric acid.

BRISTLES. The hog's bristles used in brush-making are brought in large quantities from Russia and Poland. As taken from the animal, they consist of various colours intermixed; but before use, and in some cases before importation, they are sorted by hand into the several varieties of colour termed in the trade black, gray, yellow, white, and lilies—the last-named of which are the lightest of all; but, excepting in the case of lilies, a bundle of any one of these kinds will be found to contain many shades or varieties of colour, which are carefully intermixed in the process of dressing whenever it is intended to use them together. In *dressing*, the bundle is repeatedly opened and combed with an instrument resembling a wool-comb; and, when a further separation of tints is not intended, the darker and lighter bristles are distributed as equally as possible among one another by separating and doubling the bundle. In all these operations the root-ends are carefully kept together, and in the dressing the bristles are separated into lots according to their length. If intended for fancy purposes requiring great neatness, the dressed hairs are subjected to the process of *picking*, which is frequently performed by children; in this process, every hair that differs much in colour from the mass is picked out by hand. Some bristles are also scoured or bleached, by which process they may be rendered almost perfectly white. Brush-making is the chief purpose to which bristles are applied; and the extent of some of the minor trades in this country is well illustrated by the fact that, in the three years ending with 1858, the average import of bristles was 2,500,000 pounds annually.

BRISURE, a term borrowed from the French and applied, in permanent fortification, to any part of a rampart or parapet which deviates from the general direction. Thus, in a front of fortification with retired flanks, the part of the curtain immediately contiguous to each flank, which is traced obliquely to the central part and in the direction of the produced face of the collateral bastion, is called the brisure of the curtain. An example of this kind of brisure is shown at *e* (fig. 1), in the article BASTION. In field fortification the faces of a star fort and of any indented line of parapet are called brisures.

BRITANNIA METAL, *Tutania*. An alloy of zinc, tin, copper, antimony, and lead, or bismuth in various proportions. The following are formulæ in common use:—

No. 1.	No. 2.
Tin, Brass, Antimony, Bismuth,	Arsenic, Tin, Antimony, Bismuth, Brass,
} of each equal parts.	} of each equal parts.

The above alloys are to be added to melted tin till a specimen on

cooling presents a good colour and proper degree of hardness for working.

No. 3.	No. 4.
Tin 74.7	Tin 50
Lead 16.3	Brass 40
Antimony 4.5	Antimony 10
Brass 4.5	
	100
100.0	

Nos. 3 and 4 require no farther preparation. Lead should never be present in larger quantity than 18 per cent., as even dilute vinegar would then quickly act upon and dissolve the alloy. Britannia metal is extensively used for the manufacture of such articles as coffee-pots, tea-pots, spoons, forks, &c. It is well adapted for these purposes on account of its silver-white colour; it also may be worked with considerable facility, and is susceptible of a high polish. The same care is necessary in the use of vessels made of this metal as of those made of copper, pewter, &c., namely that they be kept clean, and the access of acid substances prevented.

BRITISH GUM, *Dextrine*, *Starch Gum*, *Leicomene*, *Roasted Starch*, *Gum*, *artificial*.

A cheap substitute for gum arabic. The manufacture of this substance has lately been brought to a high state of perfection. It is obtained from starch by the action of dilute acids, diastase or heat.

To 1000 parts of starch are added 2 parts of nitric acid, diluted with sufficient water to moisten the whole mass. The mixture when dry is heated for two or three hours at a temperature of about 150° F., the heat being finally raised to 230° F.

To 400 parts of water heated in a copper to 85° F., 5 parts of crushed malt are added, and the mixture raised to 140° F., 100 parts of starch are now stirred in, and a temperature of about 150° F. maintained till the whole is changed into a viscous fluid. This usually occurs within half an hour. Immediately this state is arrived at, the heat is rapidly increased to 212° F. The diastase in the malt is thus prevented from converting the dextrine into glucose, or grape sugar: a transformation that would otherwise quickly take place. The liquid thus obtained is cleared by repose or filtration, and concentrated to a proper consistence by evaporation. The gum obtained usually contains small quantities both of starch and sugar, from which it cannot be freed without considerable trouble: their presence, however, is of little consequence for most applications of dextrine.

A third process, and the one most usually adopted, consists in simply heating the starch to a temperature a little above 300° F., till it assumes a buff colour, and is soluble in water.

British gum resembles gum arabic in all its common properties, and is used as a substitute in nearly all the applications of the latter, more especially to thicken the colours and stiffen the goods of the calico-printer, the dyer, and the paper manufacturer. It may be readily distinguished from the natural variety by the high power possessed by its solution of rotating a ray of plane polarised light to the right hand, hence the name "dextrine;" a solution of gum arabic rotating the ray to an almost equally powerful degree, but in precisely the contrary direction. Another test by which to distinguish these two gums from each other is to heat the aqueous solution over the water bath with caustic potash or soda, and a few drops of solution of sulphate of copper, when dextrine will cause a red precipitate of suboxide of copper, gum arabic not affecting the solution. Heated with strong nitric acid dextrine yields oxalic, and possibly succharic acids. Gum arabic under similar circumstances yields mucic acid.

Dextrine when pure has the same chemical composition as starch, namely, $C_{12}H_{10}O_{10}$. It is very soluble in water, less so in dilute spirit, and insoluble in absolute or tolerably strong alcohol. It is not coloured by iodine. Boiled with dilute acids it is converted into grape sugar. Subacetate of lead causes no precipitate in solutions of dextrine till ammonia is added, when a white compound falls, having the composition $C_{12}H_{10}O_{10}$, 2 Pb O. With protochloride of tin it also yields a precipitate, but none with sulphate of iron.

BRITISH MUSEUM, THE. The national museum of Great Britain, which comprises the national library, owes its origin to the will of a private individual. The founder, Sir Hans Sloane, was a native of Ireland, but of Scotch extraction, the son of a Scotchman who had emigrated to Ulster in the reign of James I. The greater part of his unusually long and fortunate life was spent in London, where for a quarter of a century he was president of the College of Physicians, as well as physician to the king, and succeeded Sir Isaac Newton as the president of the Royal Society. He died at Chelsea on the 11th of January, 1753, at the age of ninety-two. More than fifty years before he had acquired, by the bequest of his friend Mr. William Courten, an extensive and valuable museum of natural and miscellaneous curiosities, which he spent much of his time and fortune in augmenting. This collection, which had altogether cost him 50,000*l.*, he directed, by his will, to be offered to the British government for the sum of 20,000*l.*, which he stated to be in his belief not one fourth of the intrinsic value, and in case the offer should not be accepted on the part of the government within a twelvemonth, then in succession to the Academies of St. Petersburg, Paris, Berlin, and Madrid, for the same sum, with the proviso that in case of refusal by all these it should be disposed of for the benefit of his daughters. Fortunately

the proposal was at once accepted, and an Act of Parliament (26 George II. c. 22) secured the prize. The same Act of Parliament showed that a new spirit had been awakened in the legislature by providing for the purchase of the great Harleian collection of manuscripts for the sum of 10,000*l*. A few years before the great Harleian library of printed books, brought together by the same collectors, Harley the statesman Earl of Oxford and his son, had been allowed to be dispersed, to the irreparable loss of the national literature. The act directed also that the Cottonian library, which had become public property in 1700, apparently by donation from its proprietor, Sir John Cotton, should be added to the new establishment, which was to bear the name of the "British Museum."

Sir Hans Sloane had in his will named fifty persons whom he requested to act as trustees of his collection, and thirty other persons of high official rank and distinction, whom he requested to act as "Visitors," in the sense in which that word is used in connexion with the colleges at the universities, in which the Visitors have the right of examining into the observance of the statutes. The Act of Parliament made no appointment of visitors, but vested the government of the museum in a body of forty-one trustees, of whom six were family trustees, or representatives of the Sloane, the Cotton, and the Harley families; and twenty official trustees, as the Archbishop of Canterbury, the Lord Chancellor, the Speaker of the House of Commons, the Secretaries of State, and others, who were to elect the remaining fifteen in consideration of personal merits and fitness.

One of the first duties of this body was to consider where the new establishment should be located. Sir Hans Sloane had contemplated its conservation at the manor-house of Chelsea, which was included in the sale of the museum, but on consideration the trustees decided against this arrangement, and presented the manor-house to the family. Two mansions were offered the trustees for purchase—Buckingham House in St. James's Park, which afterwards became the Queen's House, and has since become the royal palace, and Montague House in Great Russell Street, immediately adjacent to Bloomsbury Square, at one corner of which Sir Hans Sloane had resided till at the age of eighty he relinquished his profession and retired to Chelsea. For Buckingham House, with its grounds and gardens, the price asked was 30,000*l*., and for Montague House, also with noble gardens covering seven acres and a half, little more than 10,000*l*. Montague House was selected, and the choice was a most fortunate one. At that time the building stood on the very outskirts of town, so much so indeed that the "fields behind Montague House" were still the favourite resort of duellists, and the view from the back windows stretched without interruption to the sister hills of Highgate and Hampstead, which bounded the horizon. It was nevertheless close to the main thoroughfare of Holborn, and to the Oxford Road, as Oxford Street was then called, and the only drawback to the advantage of the situation was that the wretched district of St. Giles's was in the immediate vicinity. In the century which followed, the open fields to the northward, eastward, and westward, were covered with miles of building, but this immense extension of the metropolis had the advantage of making the situation of the Museum more central. The new buildings in its immediate neighbourhood, forming the pleasant district called "the Squares," are of the tranquil and respectable character, best suited to the contiguity of a museum. The destruction of the old dens of St. Giles's, and the formation of New Oxford Street on their site, have placed it in the enviable position of standing in a quiet street, yet in the immediate neighbourhood of one of the most brilliant and crowded thoroughfares in London, and if the proposed continuation of Tottenham Court Road to Trafalgar Square be ever effected, it will be within a few minutes' walk of the point where two great thoroughfares from east to west, and from south to north will intersect each other.

The building which first received and for many years contained the British Museum was reputed to have been erected by a Frenchman, and was certainly adorned exclusively by French artists, a circumstance which gave rise to the popular but improbable notion, that the cost of it had been defrayed by the king of France. Ralph Montague, afterwards Baron and Duke of Montague, ambassador from James II. to Louis XIV., had about 1674 erected on the site a mansion of more than ordinary splendour from the designs of Robert Hooke, the mathematician, but in 1686, owing to the negligence of a servant the building was burned to the ground. It has been often stated that the architect of the new structure was Pierre Puget, of Marseille, eminent as a sculptor, painter, and both civil and naval architect, and that he was sent from Paris expressly to superintend it, but in the 'Biographie Universelle,' no mention is made of his having come to England, and the building bore no trace of the peculiar style which induced some to call him the French Michel Angelo. The new mansion was raised on the foundations of its predecessor. Towards Great Russell Street, it simply presented a sparingly ornamented brick wall, with an entrance in the centre surmounted by a small cupola, and with two peaked turrets at the ends. On passing through the gateway, the visitor found himself under an Ionic colonnade on one side of a large courtyard, on the northern side of which, immediately fronting him was the main building, a somewhat plain and unpretending edifice of brick, with stone dressings, 216 feet in length and 57 feet high, with a flight of steps leading up to the main door. On the two other sides of

the courtyard were the offices of the mansion, which, during the time of its occupation as the Museum, were appropriated to the residence of some of its officers. A view of the front on a large scale may be found in Strype's 'Survey of London,' for 1754. The visitor, who crossing the courtyard entered the building, found himself in a stately hall at the foot of the grand staircase, which was one of the most striking features in the interior architecture, and a representation of which is given in Ackermann's 'Microcosm of London.' Its walls and ceiling, and the walls and ceilings of all the principal rooms were adorned with fresco paintings by three French artists, Charles de la Fosse, Jacques Rousseau, and Jean Baptiste Monoyer, executed with admirable skill, and representing flowers and dead game, as well as several of the stories in Ovid's 'Metamorphoses.' The show rooms, twelve on the ground-floor, and as many on the first floor, were in general stately and well lighted, the front row looking on the courtyard, and the back on the garden. A ground-plan of the whole was published in Dodsley's 'London and its Environs,' in 1761, and another in Britton and Pugin's 'Public Edifices of London,' in 1823.

Such was the Museum, which after some years of preparation was opened for public inspection for the first time on the 15th of January, 1759. The establishment then consisted of three departments only, the printed books, the manuscripts, and the natural history. The earliest regulations for the admission of the public were extremely different from those now in force at the Museum, but they bear some resemblance to those which are still observed at the Soane Museum in Lincoln's-inn-Fields. It was provided by the regulations that "admission to such studious and curious persons who are desirous to see the Museum" should be obtained by means of "printed tickets, to be delivered by the porter upon their application in writing, which writing shall contain their names, condition, and places of abode, also the day and hour at which they desire to be admitted." This list was to be submitted every night to the principal librarian, or in his absence to another officer of the Museum, who, if he considered the parties admissible, was to "direct the porter to deliver tickets to them according to their said request, on their applying a second time for the said tickets," observing, however, that not more than ten tickets were delivered for each time of admission. The parties who produced these tickets were to be allowed three hours of inspection of the Museum, spending one hour in each department, and being taken in charge by a different officer for each, and the regulations for their reception are so detailed as to occupy about four pages octavo in Dodsley's 'London and its Environs.' How they operated in some cases may be learned from the account of a visit which was paid to the Museum by Hutton, the historian of Birmingham, in December 1784, and which he described in his "Journey from Birmingham to London," published in the following year. Hutton, who had but a few days to stay in the metropolis, was unwilling to quit it without viewing the Museum, but "how to accomplish it was," he says, "the question. I was given to understand that the door, contrary to other doors, would not open with a silver key, that interest must be made some time before, and admission granted by a ticket on a future day. . . . By good fortune I stumbled on a person possessed of a ticket for the next day, which he valued less than two shillings; we struck a bargain in a moment and were both pleased." When he gained admission, he was hurried through the rooms, he tells us, in about thirty minutes by a surly conductor, who was both unwilling and unable to explain the curiosities, and he left in great dissatisfaction. "I had laid more stress," he says, "on the British Museum than on anything I should see in London. It was the only sight that disgusted me." The system which he thus described continued for many years longer, probably till 1803, when several alterations in the management took place. In the first 'Synopsis,' or official guide to the Museum, published in 1808, it is stated, that on the first four days of the week, 120 persons may be admitted to view the Museum, in eight companies of 15 each; but no mention is made of the necessity of their previously obtaining tickets. In the 'Synopsis' for 1810, a great advance appears: "According to the present regulation," it is stated, "the Museum is open for public inspection on the Monday, Wednesday, and Friday in every week (the usual vacations excepted), from ten till four o'clock, and all persons of decent appearance who apply between the hours of ten and two are immediately admitted, and may tarry in the apartments or the gallery of antiquities without any limitation of time, except the shutting of the house at four o'clock." From that period the regulations have been constantly growing more liberal, and the increase in the number of persons admitted in the course of a year is striking, though there has been some ebb as well as flow. The numbers in several twelvemonths, as given in the returns, are as follows:—

From May, 1807, to May, 1808	13,046
From March, 1817, to March, 1818	50,172
From Christmas, 1827, to Christmas, 1828	81,228
From Christmas, 1837, to Christmas, 1838	266,008
From Christmas, 1847, to Christmas, 1848	897,985

In the year 1850, the numbers were just above a million; in the following, or "Exhibition year," when multitudes flocked to the Crystal Palace, the astonishing number of 2,527,216 was attained, a cipher surpassing that of the whole population of London. Since

then the amount has never risen to 700,000. In 1858 it was 519,565. The greatest number, however, that ever entered the Museum in one day was on the Boxing-day of Christmas, 1858, when there were upwards of 42,000. It is a circumstance that says much, that with this vast multitude of visitors, the only conspicuous act of destruction of the Museum property that has occurred was the act of a madman—the breaking of the Portland vase in 1845. The demeanour of the public in general has been excellent.

The Act of Parliament for founding the Museum had directed 100,000*l.* to be raised for the purpose by way of lottery, a method to which no objection appears to have been suggested in any quarter. Out of this sum, 10,250*l.* were paid to Lord Halifax for Montague House, and 12,873*l.* were expended in its repairs, which, characteristically enough, had been estimated in 1754 by three surveyors at 3800*l.*: 30,000*l.* were set apart as a fund for the payment of salaries, taxes, and other expenses. The salaries established at the outset appear on a very moderate scale indeed: the principal librarian received 212*l.* a year, the under-librarians for the three departments into which the Museum was divided 108*l.* each, and the assistant-librarians 69*l.* 6*s.* 8*d.* They continued apparently at this rate for about forty years; but a nearer examination shows that during most of that period the attendance of the officers was only given on two days in a week for two hours each time, and on three days in the following week for two hours each, and so by alternate weeks throughout the year; or, on an average, that the attendance of the officers was for five hours a week, instead of, at present, six hours a day. For any extra attendance they received extra compensation. No intention appears to have existed at first to make augmentations of the Museum to any considerable extent: according to a return made to the House of Commons in June, 1847, the amount of money expended in purchases in the year 1766 was only 2*l.* 8*s.* 6*d.*, and in 1768, 1*l.* 10*s.* 6*d.*, in each case for additions to the department of printed books. The sums expended did not continue so excessively low as this; but only on five occasions during the forty-one years which elapsed from the opening of the Museum to the close of the 18th century is the regular annual expenditure of the Museum on purchases recorded to have exceeded 400*l.*

With the beginning of the 19th century the character of the Museum began to change, and, gradually, from a stationary it became an eminently progressive institution. The adoption of the more liberal system of admission, both to the Museum in general and to its reading-room, appears to have given an impulse to improvement by arousing the interest of the public in its welfare, and thus favouring the application to the legislature for grants for its increase. The votes for purchases began to grow perceptibly larger towards the conclusion of the reign of George IV., and after the passing of the Reform Bill. For the ten years which ended in 1806, the total given in the return to the House of Commons, in 1847, is 4401*l.* 8*s.* 8*d.*; for the ten years to 1816, 78,173*l.* 18*s.* 1*d.*; but this is evidently swelled by the grant of 35,000*l.* for the Elgin Gallery, the largest grant for a purchase the Museum has ever received. In the ten years to 1826, the total had again sunk to 30,583*l.* 5*s.* 5*d.*; in those to 1836 it rose to 49,434*l.* 11*s.* The average of the grants in the succeeding ten years was over 16,000*l.* a-year. In the estimates for 1859, the amount proposed to be granted for purchases and acquisitions is 21,955*l.*: of which 10,000*l.* are for the Printed Book Department; 2550*l.* for that of Manuscripts; 820*l.* for the Minerals; 820*l.* for Geology; 1525*l.* for Zoology; 175*l.* for Botany; 3050*l.* for Coins and Antiquities; 2115*l.* for Prints and Drawings; leaving 1000*l.* for freight and carriage.

Many of the great purchases of the Museum have been effected by special grants, which will be found recorded in the outline of the history and state of the separate departments which follows this sketch of the general history of the establishment. We will now pursue the history of the building.

Large acquisitions of antiquities in 1801 and 1805 led to the establishment of a separate department of antiquities in the Museum, and to the erection of a new edifice of thirteen rooms in the gardens to receive the new treasures. This building, which communicated by a passage with old Montague House, was of an entirely different architectural character, and offered to the London public for the first time a series of classical saloons suited to the idea of a Museum. It was opened in 1807, and did credit to its architect, Mr. Saunders. The subsequent acquisition, in 1816, of the Elgin marbles, which were for some years exhibited in a wooden shed, rendered familiar the contemplation of further extension of the building; and the presentation of the library of George III. in 1821 made it imperative to provide a suitable room for its reception, which was one of the conditions of the gift.

The design for the King's Library, which was prepared on that occasion by Sir Robert Smirke, the architect of the Museum, formed part of a general design for rebuilding the whole Museum, involving the demolition not only of Montague House, but of the saloons for the department of antiquities constructed by Mr. Saunders. Sir Robert's proposals were adopted by the Trustees and in the course of the twenty-five years from 1823 to 1847 were carried into execution. In place of the former brick wall in Great Russell Street a splendid partially-gilded railing now allows the passenger to survey the magnificently enriched front of the new edifice, presenting a recessed portico and two projecting wings, each clothed in Ionic columns, the

whole forming a forest of columns forty-four in number, which from fronting to the south have a play of light and shade such as no other portico in London presents. On each side, a range of officers' houses encloses the court-yard, through which the visitor proceeds to the principal entrance, where, as before, he finds a spacious hall, with, on the left-hand side, the principal staircase. The building erected by Sir Robert Smirke consists of four ranges of apartments,—east, west, north, and south,—which enclose a hollow square or large open quadrangle in the centre. The eastern range, which was built and in use some years previous to the gradual erection of the others, contains some apartments appropriated to the manuscript collection, and also the Royal Library, a magnificent apartment 300 feet in length and 40 wide, with inlaid floor and coffered ceiling. The northern range of apartments, is allotted to the general library, and is less ornate in appearance than the eastern range, but contains one room called "the Main Library," of the dimensions of 84 feet by 80, which is of a striking character. The western range, erected partly on the site of Mr. Saunders's building, presents one large apartment 300 feet in length, appropriated to Egyptian and other sculpture. The southern range, which was the last to be completed, occupies the site of old Montague House, and contains the great hall and staircase, to which we have now returned by performing the circuit of the building, with to the east of the hall a room containing the Grenville library, and to the west of the hall a saloon containing antiquities. The whole of this long extent of building on the principal floor is of the height of 31 feet, lighted by large windows, which are at the height of nearly 14 feet from the floor. Its general character is classical, and its features almost invariably square or oblong, the arch and circle being apparently avoided with care throughout; and from the height of the windows, which are in some cases flanked by columns outside, there is in some portions a deficiency of light. The less important range of rooms on the floor above is lighted invariably by skylights, an arrangement which allows more wall-space for the exhibition of objects. Commencing with the eastern range, as in the case of the floor below, we first find a long gallery of the same dimensions, except in height, as the Royal Library, over which it stands. This room was originally designed by Sir Robert Smirke for the reception of the National Gallery of pictures, but was never used for that purpose, having first been appropriated to the mineralogical, and afterwards, as it is now (in 1859), to the ornithological collection. The rooms in the other three ranges of building are all much of the same character, and in no instance of very large dimensions; they are all fitted up with plain glass cases against the walls and in the middle for the exhibition of the objects they contain,—the mineralogical and part of the natural history collection in the northern range, the antiquities in the western and in the division of the southern gallery to the west of the great staircase, while the botany occupies the division to the east. The ranges of apartments on this floor, while of good dimensions and not unornamental, can hardly be considered as advancing any pretensions to high architectural character.

Such is the great edifice of Sir Robert Smirke, which, even if it stood thus without any additions, might yet claim to be the first in importance and splendour of the unecclesiastical edifices of the British metropolis, with one exception which was not in existence or contemplation at the time his design commenced—the Houses of Parliament. But even before the grand square had slowly worked its way to completion, it was discovered that the space its apartments afforded was insufficient for the continually increasing needs of the Museum. A gallery or saloon for the Elgin marbles was constructed by erecting a fresh building to the west of the western range, and other similar rooms for the reception of other collections have since been added communicating with it. Further accommodation for the library was procured by building what is called "the Arch-room," in continuation of the northern wing towards the west. In this case the wishes of the librarian, as well as the architect, were taken into consideration, and the result was gratifying even in an architectural point of view. Room for books was gained by a second gallery on arches, and additional light by the insertion of a large arched window in the principal floor, the only window on that floor which the building contains. The visitor who stands at the point where the eastern and northern ranges of building intersect, and first surveys in one direction the long array of 300 feet of glazed book-cases in the Royal Library, meets, as he turns in the other direction, the flood of light from the great window, at the end of the long perspective of more than 450 feet of book-filled recesses, which stretch from one end to the other of the northern range. These improvements owe their origin to the librarian, Mr. Panizzi; and to him is due also the suggestion of an additional room for books at the eastern or exterior side of the King's Library,—a room which, though only of half the height and half the breadth of that beside which it stands, and thus only a quarter of its dimensions, was finally adapted by an economical disposition of its space to receive fully the same number of volumes. When even all the room thus gained had been appropriated, and more was still wanting for the library, which began to overflow into the basement, a serious question arose, of how to provide space for the increase of the Museum. Some discussion has arisen as to the priority of suggestions on the subject, and Mr. Hosking, an architect, who published a pamphlet of 'Observations on the Reading-room' in 1858, assigns the earliest notion

of building in the hollow square or quadrangle of the main building to Mr. Edward Hawkins in 1842; but the idea will be found in a series of letters on the Museum, which were published anonymously in the 'Mechanics' Magazine' for 1836 and 1837, but have since been acknowledged by Mr. Watts, now one of the officers of the Printed Book department. "The space thus unfortunately wasted," says Mr. Watts, speaking of the quadrangle ('Mechanics' Magazine,' vol. xxvi. p. 457), "would have provided accommodation for the whole library. A reading-room of ample dimensions might have stood in the centre, and been surrounded on all four sides by galleries for the books communicating with each other and lighted from the top." "Perhaps the best plan," he suggests, in another part of the same paper, "would be to design another range of building entirely inclosing the present at the eastern and northern sides, as the Elgin gallery, &c., do on the west." Each of these plans was proposed many years after to the Lords of the Treasury by the trustees of the Museum; but that of encircling the present Museum with a belt of additional buildings would of necessity have required the demolition of the ranges of valuable private houses which at present occupy the site; and as the expense of thus clearing the ground was estimated at a quarter of a million, the plan was rejected as too costly. In 1852, and again in 1854, Mr. Panizzi proposed the plan of covering the quadrangle, which was at length adopted, and in the very centre of the Museum now rises a reading-room of truly "ample dimensions, surrounded on all four sides by galleries for the books, lighted from the top."

The new reading-room is now one of the principal architectural features of the Museum, and is the only one that is visible at a distance, the dome that crowns it forming part of the view of London from Hampstead Heath, and from the Norwood hills near the Crystal Palace. The approach to the room from the entrance hall of the museum is by a long passage, which is adorned with a bust of Mr. Panizzi by Marochetti,—an excellent likeness,—the result of a subscription proposed by Mr. Winter Jones, the present keeper of the printed books. On crossing the threshold the visitor finds himself in a large circular apartment crowned with a dome of the most magnificent dimensions, the largest indeed, with one exception, in the world. The diameter on the floor is 140 feet, the height from the floor to the top of the dome 106 feet; while the Pantheon at Rome, the room which it most resembles, is 142 feet in both dimensions, the drum or cylindrical portion rising to half that height before the arch begins to spring. It is contended by Mr. Hosking, who proposed in 1848 to erect on the same spot a hall for the reception of antiquities, of the exact proportions of the Pantheon, but on a reduced scale, that this departure from these proportions destroys the beauty of the reading-room; but the general opinion appears to be rather one of regret that the architect of this portion of the Museum, Mr. Sidney Smirke, did not increase his dimensions by a few feet; so that the dome, which surpasses in size that of St. Peter's at Rome, and of course its nearer neighbour St. Paul's of London, might, surpassing that of the Pantheon also, be indisputably the largest in the world. Several who have seen both buildings declare that the reading-room, as it is, produces the impression of being the larger of the two, and its arch of blue and gold gives it much the superiority in richness and lightness. Instead of the somewhat monotonous diminishing squares of the Pantheon dome, a range of twenty lofty windows, 27 feet high and 12 feet wide, run round the circle of the reading-room, and in conjunction with a lantern light of 40 feet diameter at the crown of the arch, pour a flood of light below. Under the windows the room presents a continuous circular wall of books, 25 feet high. They are disposed in presses or bookcases, accessible from the floor, or from low galleries running round the apartment, and comprise in the part open to the readers, about 20,000 volumes of books of reference and standard works, and in the part round the galleries more than 50,000 volumes of the principal sets of periodical publications, old and new, in the English, French, Italian, Spanish, German, Danish, Swedish, Dutch, Russian, Polish, Bohemian, Hungarian, Welsh, Latin, Greek, and Hebrew languages: a collection already more rich and varied than was ever before assembled under one roof, and receiving daily increase. The floor of the room is occupied with 19 large and 16 smaller tables, fitted up with ample accommodation for more than 300 readers; but, by the simple expedient of raising the partition down the middle of each of the larger tables so high that a reader cannot see his opposite neighbour, so much privacy is produced that on entering the room when it is quite full a stranger might at first suppose that it was nearly empty, and no seated reader sees more than three or four of his fellow-readers at a time. The tables are all arranged so as to converge towards the centre of the room, and near the centre are the two circular ranges of stands for the catalogue, a portion of which is thus actually at the end of every table. Directly in the centre is the table of the chief superintendent of the reading-room, a duty at present assigned to Mr. Watts, the assistant keeper of the Printed Books, who has already been mentioned as having first suggested the idea of a central reading-room. From his position, and still more from the galleries, an interesting view is commanded of all the tables and their occupants, often between two and three hundred in number, and comprising among them some of the best known names in the world of literature and learning—names that are familiar now to all the readers of Europe and America, and will be familiar in all probability centuries hence, from the very labours in which they are aided by the Museum reading-room. From the nature

of the library around them, not only such men as Carlyle and Thackeray, Kossuth and Montalembert, but the humblest labourer in the literary vineyard, from the most distant corners of the world, may be certain that on the walls around there exists some record of his labours, or the copy of some lines traced by his hand. The name of Mr. Panizzi will be inseparably connected with this, the most magnificent temple ever erected to literature, which, without his powerful influence, would probably never have existed.

The reading-room and the new library which surrounds it are constructed almost entirely of iron and brick, to guard against the danger of combustion. Even the shelves, which it is estimated will extend to about twenty-five miles in length, are partly constructed of metal. Beneath the room is a large array of pipes for heating the room in cold weather with warm water, and there are ingenious contrivances for cooling it when required. The expense of the new reading-room and its appurtenances, including the new library around it, which is to afford space for more than a million of books, amounted at the time of its being opened to the readers, on May 18th, 1857, to 150,000*l*.

All the available space under the control of the Museum being now occupied with buildings, and a strong demand still existing for space for the extension of the departments of antiquities and natural history, the question is again under consideration how this demand is to be met—whether by an extension of the present edifice, or by removing some portion of the contents of the Museum to another locality. A copy of communications made by the officers and architect of the British Museum to the trustees, respecting the want of space, was laid before the House of Commons in March, 1859. The plan at present in contemplation is understood to be that proposed by Mr. Panizzi so early as 1836, of removing the whole of the departments of natural history to some other spot, and thus allowing space for the growth of the antiquities. There is a precedent in the history of the Museum for the transfer of a portion of its property to the custody of another institution, while still retaining it under the control of the trustees. Sir George Beaumont's pictures, given by him to the Museum, are still the property of the Museum, though preserved in the National Gallery. Whatever may be the decision arrived at, it appears probable that the Museum is on the eve of another change, as important as any it has undergone.

While in other respects the Museum has witnessed so many alterations, it is remarkable that the constitution and character of its governing body remain after the lapse of more than a century nearly the same as at its origin. The Board of Trustees consisted of forty-one members,—it now, by gradual additions of official and family members, consists of fifty. The power of patronage, or of nomination to the different posts of the Museum, with the exception of that of principal librarian, is vested by act of parliament in the hands of the three principal trustees, the Archbishop of Canterbury, the Lord Chancellor, and the Speaker of the House of Commons. There are twenty-two other official trustees, the Lord President of the Council, the First Lord of the Treasury, the Lord Privy Seal, the First Lord of the Admiralty, the Lord Steward, the five principal Secretaries of State, the Bishop of London, the Chancellor of the Exchequer, the Lord Chief Justice of the Queen's Bench, the Master of the Rolls, the Lord Chief Justice of the Common Pleas, the Attorney- and Solicitor-General, the Presidents of the Royal Society, of the College of Physicians, of the Society of Antiquaries, and of the Royal Academy. Since 1832 one trustee is appointed by the sovereign, and this post which remained vacant for years after the death of the Duke of Cambridge in 1851, was filled up in 1859, by the Queen's appointment of the Rev. William Cureton, who from 1837 to 1850, was the assistant-librarian of the Manuscript department. Of the family trustees, two are representatives of the Sloane, two of the Cotton, and two of the Harley family, one of the Townley, one of the Elgin, and one of the Payne Knight family; the Earl of Derby and the Earl of Elgin are at present two of the number. The fifteen elected trustees are chosen by the other members of the board, and to attain this honour has been called "the blue riband of literature." The list of them offers the names of many illustrious persons, and in particular of many eminent benefactors to the Museum. Dr. Birch, and Sir William Musgrave, the Rev. Clayton Mordaunt Cracherode, Mr. Tyrwhitt, Sir Joseph Banks, Sir George Beaumont, and the Right Hon. Thomas Grenville, all bequeathed important donations to the Museum, and several made presents of value during their lifetime. The list of the fifteen elected trustees is at present as follows: the Earl of Aberdeen, the Marquis of Lansdowne, the Duke of Sutherland, Lord Macaulay, Sir David Dundas, Sir Philip Egerton, the Duke of Somerset, Sir Roderick Murchison, the Very Rev. H. H. Milman, Dean of St. Paul's, Lord John Russell, the Right Hon. William Ewart Gladstone, Sir George Cornewall Lewis, the Right Hon. Spencer Walpole, Viscount Eversley, and George Grote, Esq. The business of the Museum is laid before a standing committee of the trustees, consisting of the three principal trustees, and of fifteen others selected from among themselves by the main body.

At two different periods the management of the Museum by the trustees has been made the subject of public inquiry,—by a committee of the House of Commons, moved for by Mr. Hawes in 1835-36, and by a Royal Commission presided over by the Earl of Ellesmere in 1848-49. On each occasion the body of evidence taken occupied about
